When properly made semi-steel exceeds in both temperature and fluidity any other mixtures melted in the cupola. Semi-steel is made in the same cupola with regular gray iron mixtures—no extra coke—special appliances—fluxes—or new equipment are necessary.

It is made in the same heat with other mixtures—it may be melted in the early part of a heat—in the middle or last part of the regular heat. Or you may begin with 30 to 40 per cent. steel on the bed charge—run as much of this grade as required and then follow with 20 to 25 per cent. steel—or vice versa.

Mr. McLain claims that every industry has its science and up-to-date foundry practice is no longer guess work—it is a science. But science does not replace common sense; and in an industry like the metallurgy of iron and steel there can be no set rules that will cover the operations or the operators in the manufacture of every grade of castings. We need men with common sense to apply scientific facts to their individual requirements and local conditions.

He also claims that any man who believes that he can simply throw some steel scrap in with the pig iron and make good semi-steel has much to learn. But such is the custom in a large number of shops in which Mr. McLain is called in an advisory capacity.

Our Government has specified twelve million semi-steel shells to be made, and this would require an approximate of 400,000 tons of pig iron, so it behooves every up-to-date foundryman to be able to meet Government specifications and help win the war.

Another feature of semi-steel is the extraordinary uniformity of a series of samples. Although the castings are of exceedingly varying weights, some having thick sections and others very thin sections, the metal microscopically is exceedingly uniform, much more so than you find in gray iron, for the majority of foundrymen realize that where the section of a casting is light there is a tendency for the iron to be hard and brittle unless the chemical composition is modified to suit the weight of the casting.

Mr. McLain does not claim to be the first man who used steel in cupola mixtures, as for over fifty years steel was carelessly used in large castings where it did not matter how it was melted: but he has the honor of being the first man who was successful day after day in using *large percentages* of steel in castings of *light* section.

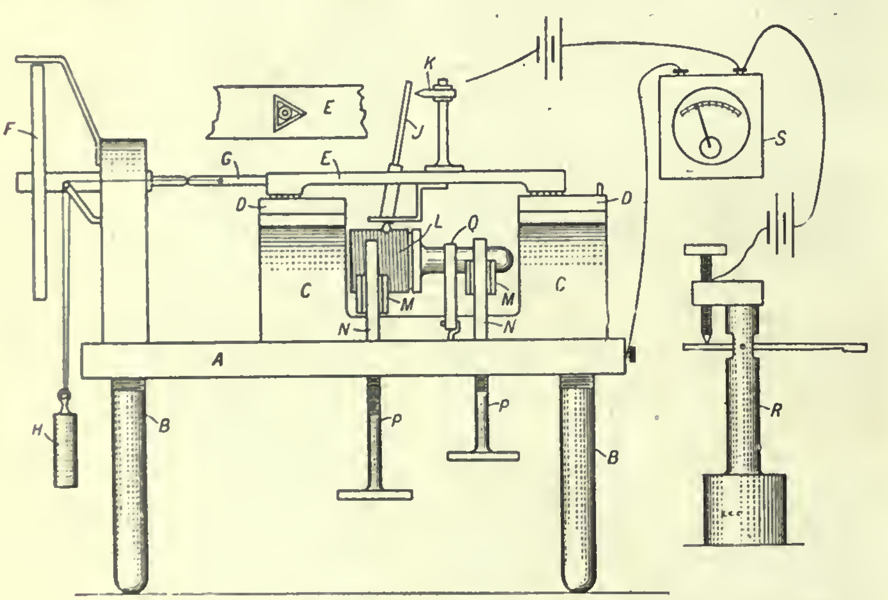
Volumes might be written about semi-steel, but the very fact that the Convention is to be held in Milwaukee will enable hundreds of foundrymen to view an exhibit of semi-steel castings made by graduates of McLain's system.

Hamilton.—The amount of work being carried on by the Dominion Foundries and Steel have made another extension necessary to their plant. This will take in three storeys and will cost about $75,-000.

PITCH MEASURING MACHINE FOR SCREW GAUGES

IT is now generally agreed that the inspection of screw gauges for the correctness of the pitches of their threads should be carried out from thread to thread, and should not be made over a given number of threads or over the threads lying within a given length, say, half an inch. The possible errors in the pitch of a thread are of two kinds, namely, variable and progressive. The error is variable if the pitch varies from thread to thread in an erratic manner. Such error may arise in a screw gauge from distortion after hardening or from faulty adjustment of the thrust bearing of the leading screw or grinding machine on which the gauge has been made. With a progressive error the pitch increases or decreases from thread to thread at a uniform rate. This defect may be due to a bad leading screw or to the lap used for finishing the gauge not having identically the same pitch as the thread on the leading screw, a possibility that may arise if the gauge and the lap are not made on the same machine.

In practice both types of error frequently occur in combination, the result being, of course, a variable error. It thus clear that the mean of the total error, measured over a number of threads, can only be a true measure of the error in any one pitch if that error is purely of the progressive type. If the pitch error is variable, or variable and progressive, the individual errors over, say half an inch, being sometimes positive and sometimes negative, may, in an extreme case, add up to zero, and in any event add up



—DIAGRAM OF THE BENGHAM-POWELL PITCH MEASURING MACHINES.

to some figure which, when divided by the number of pitches in the length chosen, cannot in general be regarded as a satisfactory measure of the error of any one pitch in the length.

Reflecting Indicator

These facts have led to the general abandonment of methods of inspecting the correctness of pitch on screw gauges based on the use of vee-pointed blocks separated by plain blocks—such as Johannsen gauge blocks—of known thicknesses. Thus the instrument now in use for this purpose at the National Physical Laboratory examines each pitch separately in succession. It consists, briefly put, of a lever carrying a ball at one end, which ball, by the action of a spring bearing against the lever, is held pressed into the threads of the gauge to be tested. As the gauge is moved past the lever the ball rides in and out over the crest of the threads down into their troughs and out again. By watching the movement of a spot of light reflected from a mirror attached to the lever, the instant at which the ball crosses the crest of a thread can be very clearly determined by means of a micrometer attachment on its carriage, and is, of course, a direct measure of the pitch between the two crests. The reversal in the motion of the spot of light which occurs when the ball reaches a crest is stated to be sharp and clearly defined, and to afford an accurate means of measuring the pitch. The method is applicable both to plug and to ring screw gauges. An instrument of this design is now in use at the laboratory of the United States Bureau of Standards.

The pitch measuring machine illustrated diagrammatically in Fig. 1 is the patented invention of Mr. H. T. Bingham Powell, the inspector in charge of the department of gauges and standards of the British Ministry of Munitions of War in the United States. It agrees with the Teddington machine in measuring by micrometeric means the individual successive pitches of the thread, and in employing a ball as a basis for so doing. But in all else it is essentially different.

The machine comprises a base A in the form of a surface plate supported at the corners on legs B screwed for levelling purposes. At the rear of the base plate a pair of overhanging cast iron brackets C are fixed, each bracket carrying a facing D of hard steel, in which double vee-ways are formed to accommodate a number of bearing balls. A carriage E, the ends of which are also formed with double vee-ways, bridges the brackets

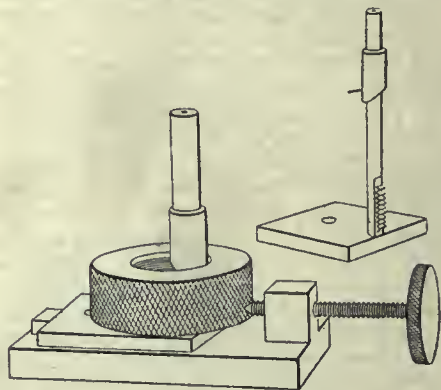


FIG. 2—TAKING A THREAD CAST.

and slides on the balls. The movement of the carriage is effected and measured by means of a micrometer head F, the spindle of which is rounded at the end and bears against the rounded end of a spindle G fixed to the carriage. The two spindles are held constantly in contact by means of a weight H united to the spindle G by a double cord passing over hooks. The micrometer head permits the easy reading of a movement of the carriage amounting to one ten-thousandth of an inch. On the axis of the carriage is a vee-shaped opening, within which there is placed a spindle J formed with a small ball at its end. The lower end of the spindle is of larger diameter than the portion above the vee-opening, and is guided between the forks of an L-shaped piece attached to the underside of the carriage. The opening between the forks is only about 1½ ten-thousandths of an inch greater than the larger diameter of the spindle. The spindle is thus practically entirely free to rise or fall or swing in the vertical plane, but is constrained from moving sideways. The end of the spindle works in conjunction with a knife-edged electrical contact K mounted between insulators on a post fixed to the top of the carriage.

The screw gauge L rests on vee-blocks, the edges of which are formed with ways so that the blocks may slide on posts N fixed into the base plate. Each block is raised or lowered by means of a fine screw P situated midway between its two posts. The gauge is held in place on the blocks by means of a stout rubber band Q passed over its handle and over hooks fixed in the base plate.

Operating Considerations

Before the apparatus is used it is most important to make sure that the tops of the threads on the gauge lie truly in a horizontal plane. For this purpose there is provided an "electric level" R, consisting of a post, the base of which is rested upon the surface plate A of the machine. The post caries a pivoted lever, one end of which is acted upon by an insulated adjusting screw. This screw is connected to a battery and a galvanometer S. is therefore in electrical connection with is connected to the surface plate A, and The second terminal of the galvanometer rises into contact with the end of the pivoted arm, and just breaks the galvanometer circuit at the point of the adjusting screw. The level is threafter transferred to the other end of the threaded part of the gauge and there used in a similar manner.

The ball point on the spindle J is then placed in the first thread on the gauge, and the carriage E moved by the micrometer wheel until the end of the spindle just makes contact with the knife edge K, a condition noted by the occurrence of a deflection at the galvanometer. The reading of the micrometer is noted and the point of the spindle transferred into the second thread. The carriage is again moved until electrical contact is once more just established. The difference between the micrometer reading in this condition and that first determined is directly equal to the length of the first pitch. The succeeding pitches are then similarly examined. The ball point and the gauge must be free from dirt and oil in order to get electric contact. This fact is a factor favoring accuracy.

To permit the pitch of a ring screw gauge to be examined in a similar way a cast is made of the threads. The material used for the cast is a composition of 7 per cent. graphite and 93 per cent. sulphur. A cast of the complete interior of the ring is not taken, for such a cast is apt to be broken during its removal, or, if the material used is at all plastic, to have all its threads, in form and pitch, a more or less exact copy of the last thread on the gauge. The simple apparatus illustrated in Fig. 2 has been devised to permit a small segment of the thread to be copied in a cast. The device consists of a small square base plate of steel ground true on the surface and provided with a spindle screwed into it exactly at right angles to its plane. The spindle is formed with a wedge-sectioned slot towards its foot. In use the ring gauge is clamped against the spindle in the manner indicated towards the left, and a sleeve surrounding the spindle is lowered to close up such portion of the slot as is not covered by the threads. The melted composition is then run into the slot and allowed to set. The cast thus left in the slot in the spindle, being at right angles to the base plate, is correctly parallel with the centre line of the gauge. Without removing it from the spindle it is taken to the pitch measuring machine and there examined. The narrow side of the slot is faced downwards in the measuring machine so that the cast will not fall out of it. The spindle is provided with centres at its ends, and can therefore be readily supported in the optical projection apparatus devised at the National Physical Laboratory for examining the angle and form of the threads.

THE ECONOMICS OF SHIP REPAIRS

By M. M.

The managers of some of the ship repairing establishments around the Coast will have some interesting jobs to describe when conditions permit, as the extent and variety of the work they have tackled during the past two years have been far in excess of any, except "freak" jobs, which were taken in hand in pre-war days. The relatively low cost of new tonnage then rendered it uneconomical to undertake any repairs which were more than reasonably lengthy and difficult, with the result that vessels were broken up which nowadays would fetch a very substantial figure even before repair. Under the system which has been set up during the past years the fullest possible advantage can be taken of the resources of the many repairing firms, from those of large size down to the smallest and least well-equipped. As a consequence the speeding up of repair work has been very marked, and it is difficult to estimate the value of the work the department responsible for repairs has accomplished.

Centralized Control

Now that there is a centralized control of repair work, it would appear practicable and also very desirable to adopt some means of disseminating such information as might be of value, regarding the manner in which certain important repairs have been effected. There is a "best" way of tackling every job—of course, dependent on the plant and equipment available—and from experience of the many repairs which have been carried out, it should be possible to arrive at the "best" method rapidly in the case of any new job. So far as one is aware, there is no such scheme for spreading useful information in this country, although everyone who has read the detailed accounts of the repairs made by the Americans to the damaged German merchant vessels cannot but be impressed by the probable value of these reports to firms who may be confronted with the work of making good somewhat similar damage. There must be very numerous cases in which damage to a vessel due to mine or torpedoes has resulted in the fracture of important hull and machinery castings, and it would be very instructive to have some idea of the manner in which these damaged items have been repaired. It is probable that the very large majority of such fractures have been made good by furnishing replace parts rather than actually repairing the castings themselves.

Replacing Castings

The policy of ordering replace castings instead of making good the broken ones is open to many objections. In the first place it is usually very wasteful of time, as such new parts have to be put through foundries already crowded with work for new vessels. Further, the length of time required for turning out a new casting is usually considereble, even if the job is given very first attention, while this latter procedure often results in a very uneconomical dislocation of the normal run of the work in the foundry. It is often necessary to patch up an old or to make a new pattern, no easy task where a stern frame or similar large part is required, while work at the vessel in the vicinity of the damaged casting is hung up until such time as the new casting has been delivered. The period for such delivery is rarely short and it may run into four or five months.

Methods of Repair

Where it is even remotely possible to effect a sound "war-time" repair by any of the several methods which can be adopted, there is no doubt but that the attempt should be made. It may not be possible to maintain the full strength of the original casting in the repair, but if a right sense of balance and proportion is brought to the consideration of the job, there is little doubt but that very many repairs which would have been considered as "not quite" satisfactory in peace time will be undoubtedly accepted as amply good enough under present conditions. After all one cannot help feeling that there is very little justification for putting, say, a brand new stern frame into a vessel which is only good for another few years, when the broken frame previously in the vessel would have been repaired sufficiently to ensure its outlasting other parts of the hull, or to put the matter in another way, when repair to the broken frame would have resulted in altering factor of safety in other parts of the ship. A vessel has a certain factor of safety when built, which factor applies more or less uniformly to the whole of the major portions of the ship structure. Deterioration naturally results in a reduction of this factor, and there are undoubtedly many vessels now on service in which the factor of safety in some portions of the vessel is a very little more than one.

Repairing Castings

As there are several methods by which it is possible to repair castings so as to obtain not less than 60 to 80 per cent. of the original strength, it would appear desirable that very careful attention should be paid to the possibility of effecting repair to the damaged item, and a replace part ordered only if it is found essential, having regard to the whole circumstances of the case. Demands on founaries are so large that everything possible should be done to relieve them. It may be thought that delay would be involved, should it finally prove absolutely necessary to order a replace casting, owing to the time spent in considering the question as to whether or not the old casting could be repaired, but this could be avoided if all the work preliminary to ordering the casting was carried out while this matter was under consideration. Further, if the services of experts in say electric welding and thermit were obtained it should be possible to rapidly arrive at sound conclusions.

Using Ball Bearings in Marine Machinery

In Sweden Great Strides Were Made in This Direction—Assist in Securing Easy and Reliable Running, and Thus Getting Greater Radius of Action—Business Growing in Canada

THE use of ball bearings in marine engines and in nautical machinery generally has been developed to an important exten in Europe by the Akti bolaget Svenska Kullagerfabriken of Gothenberg, Sweden. This concern was the original manufacturer of the S K F ball bearings which are also manufactured in the United States. The fact that these bearings are well known both in Canada and the United States will tend to create interest in some recent applications, particulars of which are given below. The installations have already proven successful and have demonstrated the efficacy of ball bearings in marine work. When constructing nautical machinery, driven either by internal combustion motors or else steam engines, unceasing efforts are made to attain the greatest possible saving in power and the most reliable running obtainable. The reason why ball bearings are of such significance in nautical machinery in general is due to the importance that is attached to easy and reliable running, factors that very largely increase the vessel's radius of action.

Connecting Rod Bearings

Ball bearings are largely used for the frames and conecting rods of internal combustion motors. In one case ball bearings were mounted in a motor with four cylinders. The bearings of the connecting rods were so large in diameter that they were slipped over the joints of the shoulders. The bearings were in all instances held fast by means of nuts against the shoulders. These bearings have also been mounted in motors with only one cylinder. In this case the shoulder is split, thus permitting the bearing rod to be mounted easily.

Propeller Shaft Bearings

The so-called "cam bearing" that has up to the present been employed for taking up the propeller pressure, has not satisfied the exacting demands that must be placed on the reliable running of a bearing of such moment for the navigation of the vessel. The loss of power entailed by gliding friction is considerable, and the propensity for becoming overheated great.

DETAIL OF THRUST BEARING FOR DIESEL ENGINE.

It can easily be understood that ball bearings have a great mission to fill, and all the applications carried out by Svenska Kullagerfabriken have given excellent results.

Besides being used on the propeller itself, ball bearings are used for supporting the propeller shaft. These bearings have been found most advantageous, especially for propeller shafts running at high speeds, or shafts of great length where the downward movement necessitates the use of a bearing constructed on self-aligning principles.

The Turbine Steamer "Mjolner"

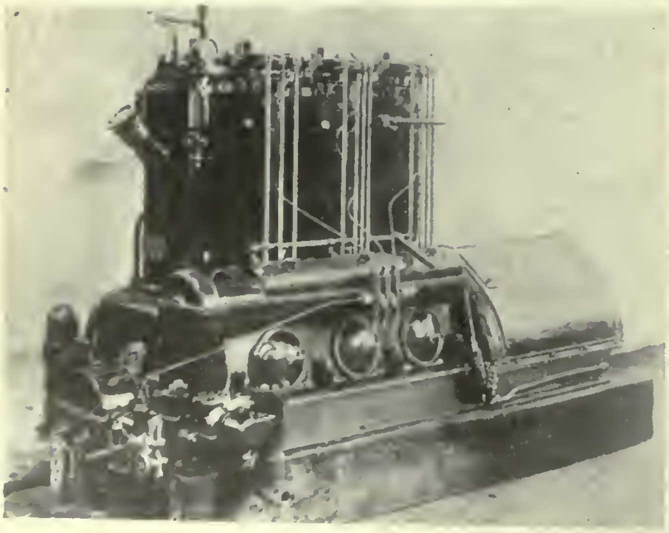
The S. S. "Mjolner," which was built some years ago and equipped with 900 h.p. motors, was fitted with ball bearings. A gliding "cam bearing" of the usual type was applied simultaneously as a reserve for taking up the propeller pressure in case the ball bearing should become unusable in any way. However, the ball bearings exceeded all expectations, for which reason the gliding bearing has now been removed.

Propeller Thrust Bearings

One of the accompanying illustrations shows a propeller equipped with ball bearings. The axial bearings are mounted on split sleeves so designed that the centre of the bearing's spherical seating coincides with the centre of the radial bearing, making the entire bearing self-aligning around this point.

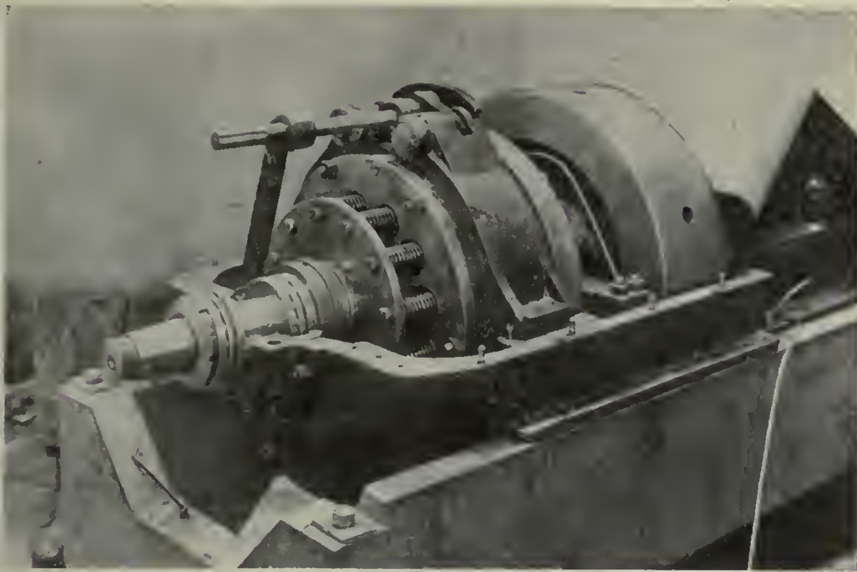
Ball bearings have been mounted on high speed propeller shafts. The propeller pressure is carried by two single thrust bearings with spherical washers; a double row radial bearing acts as a guide bearing. By suitable dimensioning of the centre sleeves, the bearing in its entirety becomes self-aligning around the centre of the radial bearing. In order to prevent the bearings from being thrown from their races by centrifugal force, a special cage is employed, consisting of a hardened and ground steel ring placed between two plate-iron discs which are riveted together.

Amongst the many advantages to be gained by using ball bearings for nautical machinery the following may be mentioned:



DIESEL ENGINE WITH BALL BEARING THRUST ARRANGEMENT.

DIESEL ENGINE WITH S K F THRUST BEARINGS FOR PROPELLOR THRUST.



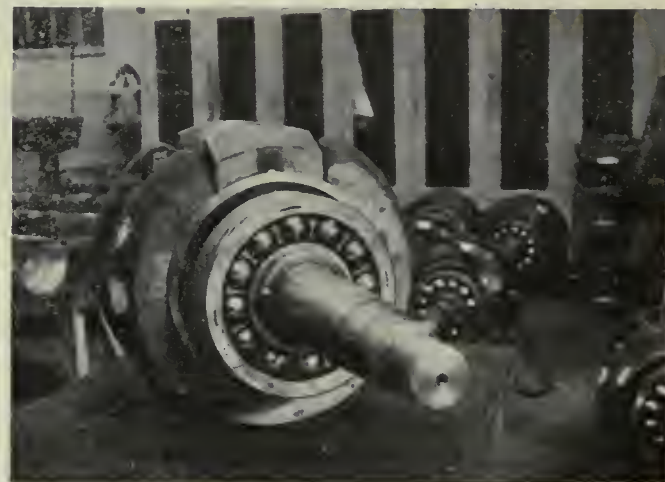
BALL BEARING ARRANGEMENT FOR TAKING THE THRUST OF THE PROPELLOR.

1. Exceedingly slight frictional resistance whilst running, which means saving in coal and the consequent enlargement of the radius of action.
2. Insignificant resistance when speeding up, making manoeuvring easier.
3. Great durability and length of life.
4. Accurate and lasting adjustment.
5. No overheating.
6. No wear on the shafts and bearing seatings.
7. Exceedingly reliable running.
8. Repairs and inspections easy and rapid.
9. Insignificant consumption of oil.
10. Easy to mount and unmount.
11. Great capabilities of self-alignment.

STEAM ENGINES FOR ROAD VEHICLES

By M. E.

The difficulty of obtaining liquid fuel of the lighter kind for road vehicles engaged on non-military work is compelling motor users to turn much more respectful attention than has hitherto been the case to the steam car working on solid fuel or heavy oils, and to the possibility of using gas in place of petrol as a fuel for existing car motors. The steam vehicle has always had, and was destined anyway to hold, its special place in the ranks of road vehicles, but in the circumstances of the hour its outlook has much improved, and efforts are being made to take full advantage of the situation. Among such efforts are the experiments that are being carried out with steam car and tractor engines designed on the uniflow principle.



S K F BALL BEARING ARRANGEMENT FOR THE MAIN SHAFT IN SINGLE CYLINDER CRUDE OIL ENGINE.

Stationary uniflow engines are now in fairly extensive use in this country, and have proved to be perhaps the most economical of all reciprocating steam engines for purposes covering a very wide field. The principle they embody is simple enough. The exhaust takes place through a ring of ports surrounding the middle of the cylinder, which are uncovered by the piston at the end of the stroke. To provide for this action the cylinder is made nearly double the length and the piston is unusually long, extending to nearly half the length of the cylinder. The gain from this arrangement arises partly from the simplicity of the engine, partly from the large exhaust-port area, partly from the fact that the direction of the steam-flow is not reversed, but, more than all, from the very favorable temperature conditions secured. Some modifications of the standard design have had to be introduced in applying the principle to road vehicles.

In the large stationary uniflow engines compression begins as soon as the piston has covered the exhaust ports. This is one of the fundamental thermodynamic principles of the engine, but it has been found necessary to moderate it for the high-speed non-condensing engine of the road vehicle by fitting an auxiliary exhaust valve which defers compression to a later stage in the stroke. The tests made thus far demonstrate that the poorest results obtained with the uniflow engine with saturated steam at 125 pounds are better than the best with any of the simple engines, even when operating condensing; that the steam consumption of the uniflow engine at 175 pounds with saturated steam, running non-condensing is lower than that of the compound non-condensing engine at 150 pounds, and the uniflow engine with steam at 180 pounds pressure and 130 degrees superheat gives a lower steam consumption than the compound condensing engine with 150 pounds pressure. These are striking and important results, portending developments which will improve a good deal the relative position of the steam vehicle.

Views and Opinions Regarding Industrial Developments, Factory Administration and Allied Topics Relating to Engineering Activity

ALTERATIONS TO SHELL LATHE IMPROVE OPERATION MATERIALLY

By Jack Homewood.

THERE are probably few operations in the manufacture of munitions that will more thoroughly test the efficiency of a machine than that of rough turning the forging of the larger shells. During the elementary stages of the shell-making industry the majority of single purpose equipment were sufficiently heavy to take care of the duty required, but with the rapid progress made in production it was invariably found that certain portions of the first machines had to be considerably strengthened to withstand the heavy cuts and continual service.

While the changes here illustrated and described might well apply to any make of lathe, the improvements were made on one of the original types of rough turning heavy duty lathes. Recent modifications, however, have incorporated many advantageous features in this and other makes of machines over those adopted in the earlier equipment.

Under the piece work system of production few operators give serious consideration to the machine itself, the first thought invariably being the "eight cents per shell," or whatever the price may be. This appears to be an unavoidable trait of human nature, but one that must receive the attention of the tool builder when designing a machine, especially for work of this character, so that it will stand up to the highest usage and abuse, thus providing a mechanical defense for the vagaries of the human element.

To maintain axial alignment of the shell during the operation of rough turning, it is necessary to exert considerable pressure at the centers to avoid the shell "backing away" and varying the gauge dimension. To meet this excessive thrust pressure on the headstock bearings and eliminate undue friction many lathes are provided with ball thrust bearings.

In this particular instance the ½-inch ball race on the front bearing was found to be too light for the heavy duty, the race showing excessive wear, together with ball breakage. To overcome this trouble the thrust was replaced with one of ⅝-inch dimension, the race rings being made from material from the forgings of 9.2 inch shells. To reduce the possibilities of further trouble an additional ball thrust bearing was placed at the rear, using ½-inch balls and an adjustable nut, as shown in Fig. 2.

The irregularity of the cut on eccentric shells was a very serious factor, as the stress imposed was frequently so great as to break off the quill or tail stock spindle, and in one instance break-

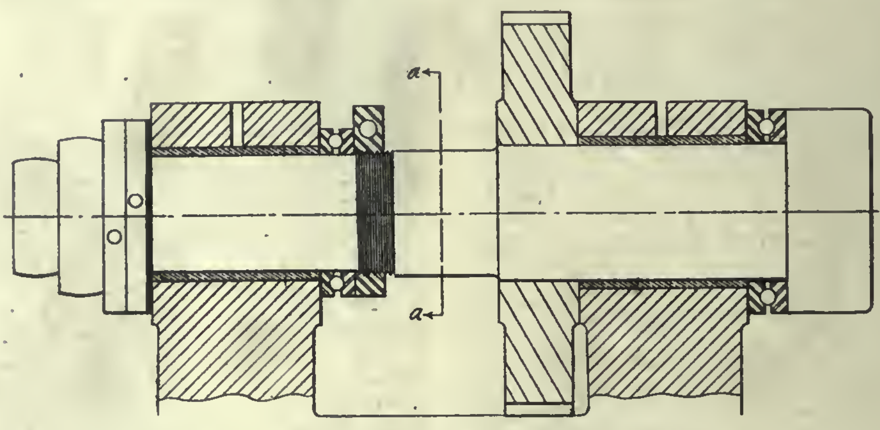

FIG. 1—THRUST ALTERATIONS TO HEADSTOCK.

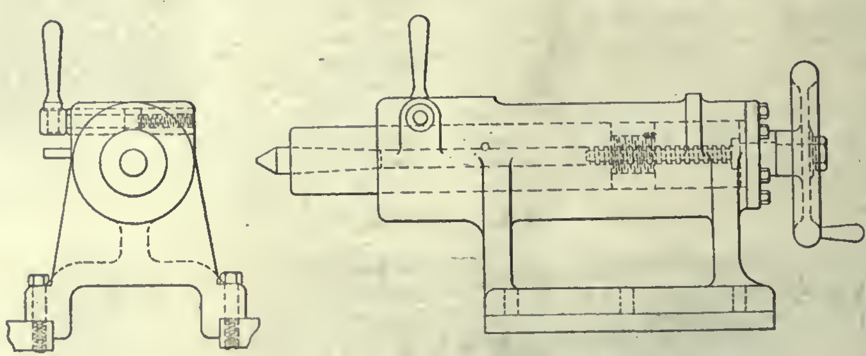

FIG. 3—INCREASING THE RIGIDITY OF THE TAIL STOCK.

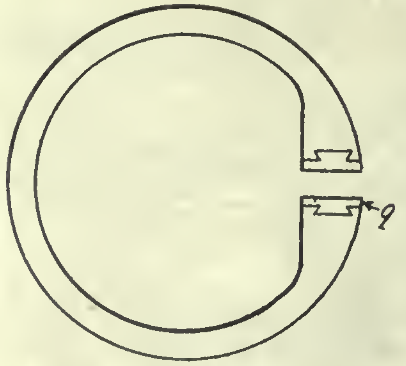

FIG. 2—VIEW OF THRUST NUT SHOWN AT AA.

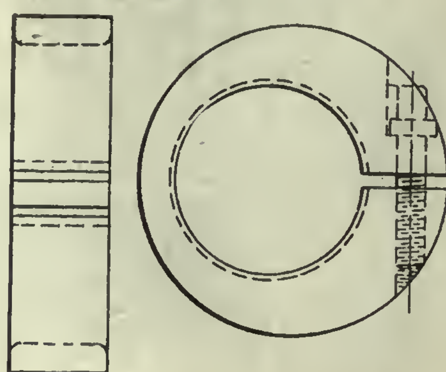

FIG. 4—CLUTCH EXPANSION RING.

ing off a portion of the supporting casting. To meet these objections the spindle was made of steel, 3 15-16 inches diameter in place of 2 15-16 inches, and the extension on the tailstock was made 7 inches in diameter and 6 inches long, against 5 inches by 3 inches in length. The tailstock was also made longer and secured in a fixed position by 6¾ inch cap-screws, three on either side. Greater thrust leverage was provided by adopting a heavier and larger handwheel.

Improvements were also made to the driving clutch ring as shown in Fig. A, the wearing surfaces being fitted with case-hardened blocks dovetailed into the expansion ring. The expansion pin was also case-hardened. Increased rigidity was given to the worm on the feed shaft by placing a supporting bracket in front and in contact with the worm. These several improvements added greatly to the life and efficiency of the machine.

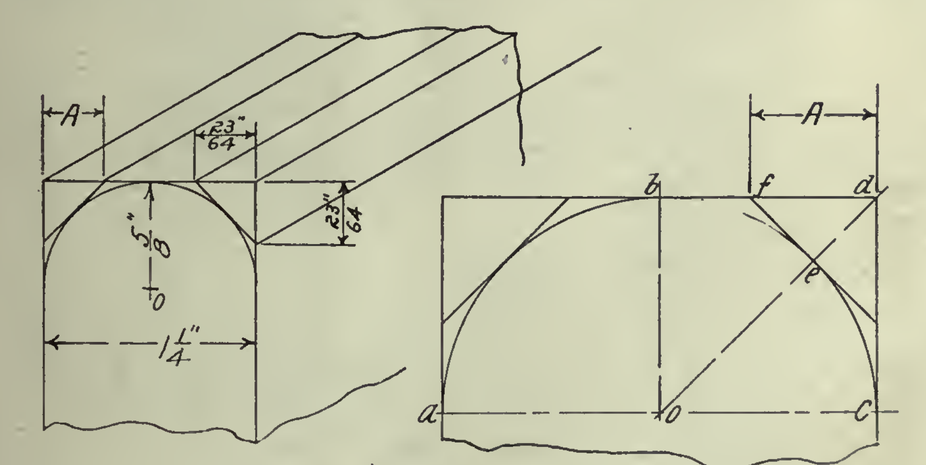
TABLE FOR ROUNDING CORNERS
BY J. W. BROADBENT

Pattern makers are frequently called upon to round off the edge of a strip to form a semi-circular cross section as shown in the sketch. On the larger pieces it is often desirable to saw strips off before finishing with the smoothing plane. To facilitate the laying off of this work the accompanying table has been prepared, giving the dimension A to be marked off from each corner so that the line b-c will be tangent to the arc required. The constants here shown are derived from the solution of right triangles, and an explanation of this might be of assistance for the solving of similar problems. In the small sketch the arc a-b-c is the one required. Suppose this is to have a diameter of 7½ inches, then the distance o-b—shown on the table with the integral number at the top and the fraction in the left hand column—will be ¾ inches. The distance o-d will be the square root of the sum of the squares of o-b and o-c, or expressed in the form of a formula o-d= $\sqrt{[(o\text{-}b)^2+(o\text{-}c)^2]}=\sqrt{[(3.75+3.75)]}=5.303$ inches. Then the distance d-c will be (o-d)—(o-3)=5.303—3.75=1.553 inches. The distance A desired will then form the hypotenuse of the right triangle d-c-f.

Again d-f = $\sqrt{[(c\text{-}f)^2+(c\text{-}d)^2]}=\sqrt{[1.533+1.553^2]}=2.196$ inches. This dimension to the nearest 64th will be 2 12-64 or 2 3-16 inches.

Table for Rounding Corners.

		1	2	3
		37/64	1-11/64	1-49/64
⅛	5/64	21/64	1-1/4	1-53/64
¼	9/64	47/64	1- 5/16	1-29/32
⅜	7/32	51/64	1-13/32	1-31/64
½	9/32	7/8	1-15/32	2-3/64
⅝	23/64	61/64	1-35/64	2-1/8
¾	7/16	1-1/32	1-5/8	2-8/16
⅞	33/64	1-3/32	1-45/64	2-17/61



METHOD OF ROUNDING OFF CORNERS

LOSS DUE TO SOOT

Soot, as is well known, is a bad conductor of heat. The loss of heat conductively in a boiler due to this is calculated as 9.5 per cent. for soot layer one-thirty-second of an inch thick; 26 per cent. for double that thickness; 45 per cent. if the layer is one-eighth of an inch thick, and 69 per cent. of it if three-sixteenths of an inch thick.

REMOVAL OF OIL FROM FEED WATER

The majority of the reported cases of boiler bagging are due to the presence of scale or oil in the boiler. The removal of the former may be accomplished by what has been termed the "periodical clean" method—that is to say by the use of mechanical cleaning methods each time the boiler is opened for inspection, by the introduction of boiler compounds, or by treating the feed water chemically. No amount of chemical treatment will remove oil from feed-water, however, and some mechanical filtering process must be relied upon for its elimination. Some engineers favor cloth filters and some sawdust, sand, or other substances, but most depends upon the design of the filter itself, and individual manufacturers of these apparatus may be relied upon to adopt the filtering medium which is best suited to their own construction.

With regard to the comparative harmful properties of various oils, the most dangerous bags and blisters are generally caused by animal and vegetable compounds, with or without the additional presence of scale. Attempts to boil them out with soda or some alkali are to be severely condemned as rendering the oils more dangerous still. As has been stated no amount of boiler compound can counteract the ill-effects of oil entrained in feed water, it being imperative that some external mechanical means be adopted when it is present.

CHART SHOWING CHIMNEY LOSSES

THIS handy chart has been developed by the Uehling Instrument Co., 71 Broadway, New York, and it is of interest and value at the present time when the coal problem is so important, for it enables anyone to quickly and closely estimate the money now being lost up almost any chimney due to low CO_2.

Simply connect the percentage of CO_2 (shown in column C) with the money now being spent per year for coal (shown in column A), and the intersection of the connecting line with column B immediately gives the dollars rolling out of the chimney in the form of heated gases.

Example: If $20,000 is spent per year for coal burned in a furnace whose average CO_2 registers 9.3 per cent., what is the approximate money lost up the chimney per year?

Solution: Connect the $20,000 (column A) with the 9.3 per cent. (column C), as indicated by the dotted line drawn across this chart, and the intersection with column B shows the approximate yearly loss to be $5,000.

The object of this chart is to show that a high percentage of CO_2 is most desirable. To be sure, even where the CO_2 is as high as 21 per cent. the theoretical maximum there is a loss, because in the average power plant the flue gases leaving the boiler have a temperature as high as 500° or 600° F. Loss, therefore, is inevitable unless a blower is used for exhausting the gases, and some sort of interchange system is installed for either heating the feed water or preheating air and leading it under the grate.

It is significant that most of the large power plants of to-day have adopted CO_2 instruments that record automatically and continuously. The reason for this is to keep constant tab on the workers in the boiler room and the efficiency of combustion. The recorder may be placed at any convenient distance from the boiler, in the office of the chief engineer, owner, manager or superintendent, while an auxiliary CO_2 indicator is placed on the boiler front in full view of the fireman. The function of the indicator is to keep the fireman constantly informed as to the efficiency of his own work. This feature is most commendable.

Coal cannot be saved by a CO_2 machine alone. If no attention is paid to the indicator or recorder, the installation of such apparatus borders on foolishness. The records should be carefully watched and studied, and adjustments should constantly be made in firing methods until the best percentage of CO 2 is obtained. After the best mark is reached, fluctuation of the CO 2 line below that mark to any great extent should not be allowed.

This chart is based on a flue gas temperature of 600° F., and an outside air temperature of 60° F. Where the flue gas temperature is higher, or the outside air temperature lower, the money loss will be correspondingly increased. On the other hand, with a higher outside air temperature and a lower flue gas temperature, the money loss is proportionately decreased. Further, in the construction of this chart it has been assumed that the coal has a calorific value of 14,500 B.t.u. per lb. of combustible.

It may also be interesting to point out that where there is only 3 per cent. of CO 2 in the flue gases 76 per cent. of the heat value of the coal passes up the chimney as waste under the conditions outlined above. It is impossible, however, for these gases to contain as low as 2 per cent., because it would require more than the original quantity of heat in the coal to heat the enormous surplus of air to a temperature of 600° F.

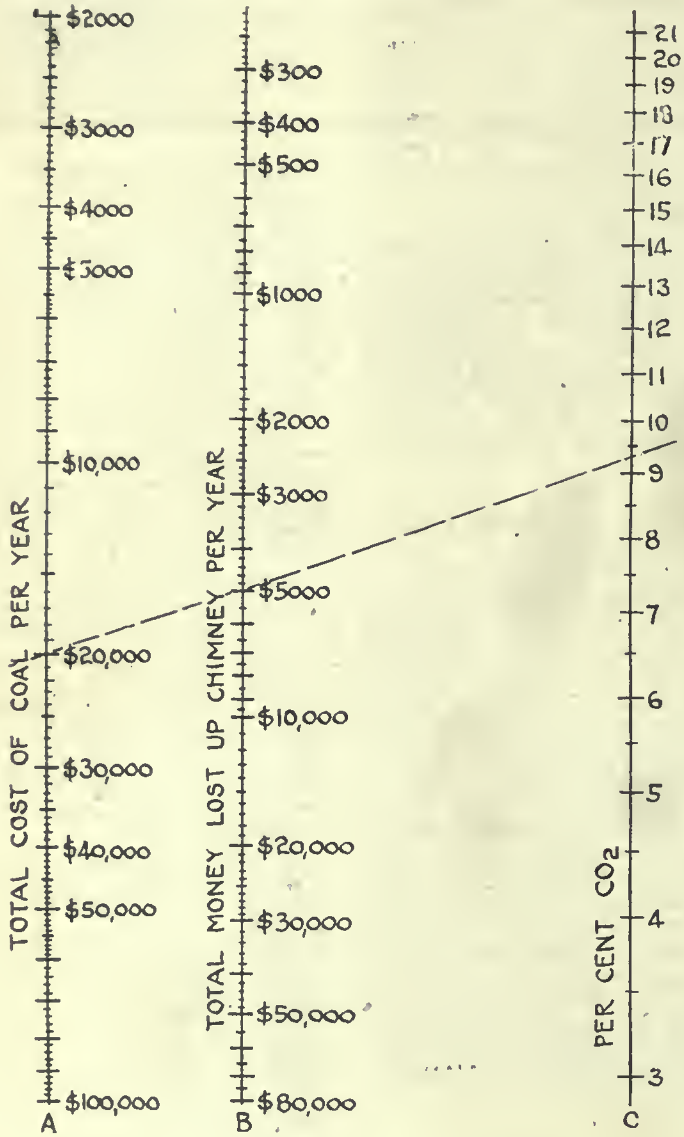


CHART SHOWING CHIMNEY LOSSES

COMPOSITE SHIP CONSTRUCTION

By Mark Meredith.

THERE has always existed a considerable amount of speculation as to what characteristics are peculiar to the method of ship construction known as the composite" method, and this term is peculiarly applied to those ships where the vessels are framed internally with metal and planked with wood. The invention of composite shipbuilding is usually ascribed to John Jordon, a member of the firm of L. H. McIntyre & Co., who were shipbuilders in Liverpool in the early days of 1840. He obtained a patent for this method of ship construction, and in 1850 the McIntyres built the schooner "Excelsior" upon this principle, and the barque "Marion McIntyre" in 1851, these being the first composite vessels ever constructed. However, Jordon's system did not attract much attention until the year 1863, when a number of British clipper ships were built for the China tea trade. There were the "Taoping," built by Robert Steele & Sons; "Eliza Shaw," by Alexander Stephen, and "Yang-tze" and "Black Prince," by Alexander Hall. These four ships gave such good account of themselves that from that time onwards all tea clippers were composite built, although it was not until 1867 that the committee of Lloyd's Register issued the first rules for composite construction.

This method of ship construction was also used for naval vessels, and during the period 1870 to 1880 a number of sloops and light cruisers were put into commission for the British Navy, and there are in the service of the United States Navy to-day the composite-built gunboats "Paducah," "Marietta," "Wheeling," "Princeton," and "Annapolis," which were completed between the years 1896 and 1904. These vessels were intended for service in tropical waters, where fouling of the bottom is very extensive, and here the advantage of composite construction was shown to be great.

In Jordon's system of building composite ships the whole outer skin, including keel, stem, stern-post and planking, is of wood, arranged as in the skin of an ordinary wooden ship, and the framework of the inside of the skin, including beams, frames, kelsons, stringers, shelf-pieces, waterways, hooks, transoms, diagonal braces, etc., is of iron, arranged almost the same as in an ordinary iron ship, channel, or trough-shaped iron being used for the frames. The bolts which fasten the skin to the frames are of iron, generally galvanized or coated with zinc, and their outer ends are countersunk in holes of such a depth that the iron bolts can be electrically insulated from the copper sheathing by plugging the holes with pitch or some other suitable non-conductor of electricity. But this system made it very difficult to keep a vessel perfectly tight. Therefore, McLain proposed that to keep the leakage free from the iron of the structure vessels should be built as regards keel, stem, stern-post frame and outer planking the same as those of an ordinary wooden vessel; but instead of the ceiling and inside the planking being composed of wood, it was to be constructed of iron, united all round at the bottom and ends of the vessel, and made thoroughly watertight, forming a complete inner skin, with beams, stringers, keelsons, bulkheads, platforms, etc., also of iron. The greater part of the wooden frame was merely of dimensions sufficient for bolting the wooden planking to, and was inserted between the iron frames riveted all round the outside of the iron ceiling. The wooden frames were fastened to the iron frames by galvanized iron fore-and-aft bolts, either screwed or plain. The wooden floorings were made deep in the throat and stiffened with plates on each side, riveted to the angle-iron frames, or iron floors were fitted inside the iron ceiling to supply the requisite transverse strength. The apron, innerpost and deadweight were inserted between and bolted to large angle-iron riveted on the iron ceiling. The outer planking within the influences of the copper sheeting was fastened to the wooden frame with screw tree-nails, or with yellow metal bolts. This system of building composite ships was intended chiefly for armor-clad war vessels.

DEVELOPMENTS IN SHOP EQUIPMENT

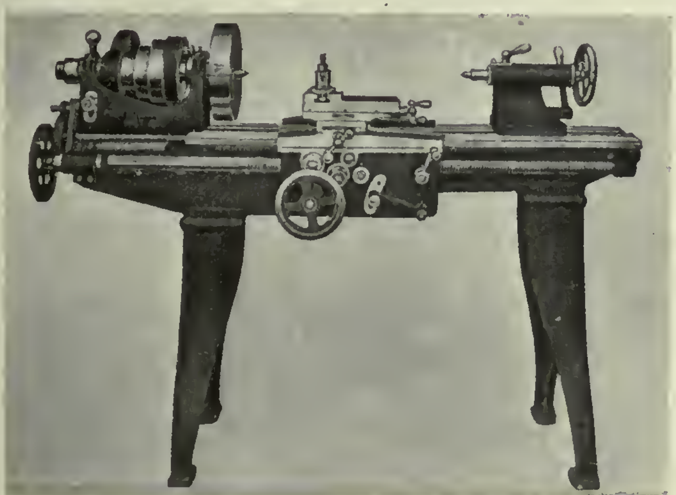
Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.

SCREW CUTTING ENGINE LATHE WITH GAP

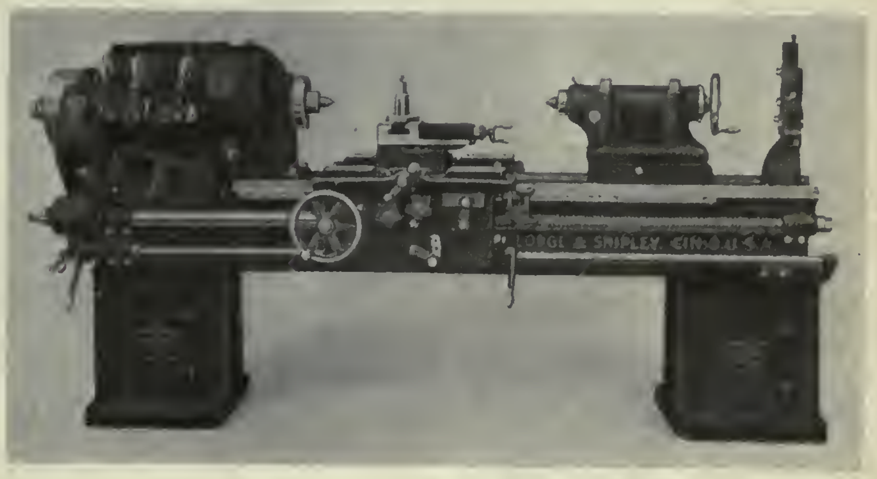
THE screw-cutting engine lathe illustrated herewith has been brought out by the Perfect Machine Co., Galt, to fill the need of a high-grade machine for manufacturing plants making light parts and for experimental purposes.

The headstock is of very rigid design and has a three-step cone pulley and back gears giving six spindle speeds. The spindle is forged of high carbon steel, is accurately ground and is hollow for bar work. Both bearings have split bronze bushings, providing an easy and effective way to take up wear. The end-thrust of the spindle is sustained by a screw collar. A carriage reversing mechanism for screw cutting is located in the headstock.

The leadscrew is made of high carbon steel and is very carefully cut. The threads of the leadscrew are never in use except when the lathe is cutting screws. For ordinary work an automatic friction feed driven by a spline in the leadscrew is provided. By shifting a spring lever on the outside of the apron an instantaneous reversing of the carriage is obtained. Automatic longitudinal and crossfeeds are engaged by turning knobs. The crank handle for the hand feed does not revolve while the automatic feed is working. An absolutely reliable safety device prevents the engaging of either longitudinal or cross-feed friction mechanism, while the half nuts for the screw cutting are closed.



SCCREW CUTTING ENGINE LATHE



20 IN. SELECTIVE HEAD LATHE.

20 IN. SELECTIVE HEAD LATHE

The accompanying illustration shows the Lodge and Shipley 20 in. selective head lathe featured by the Garlock Walker Co., Toronto, at Toronto Exhibition.

In the design of this lathe considerable care and effort have been expended in the design of the selective head. The sliding gears on the initial transmission shaft are mounted on a driving sleeve having four integral keys. All other shaft-driven gears are pressed and keyed to shafts. All shaft bearings are in the main headstock casting. This casting has box sections with sides extended up to the center line of the spindle, which makes an unusually rigid casting. All transmission gears are chrome nickel steel, heat treated. The face gear is of steel. A rigid casting bolted to the headstock supports the driving pulley and thus relieves the driving mechanism of all belt pull. Inside the supporting casting is a powerful cone friction. Pulley is regularly equipped with a brake which allows spindle to be stopped quickly.

The spindle has a double nose cut from the solid. The outer nose or cup is threaded internally to hold the face plate in position, and the end is faced to provide a very large diameter shoulder, against which the face plate is tightened. The inner nose is cylindrical, left blank and extends beyond the outer nose, so as to form a pilot to receive the face plate or chuck plate. This pilot at all times accurately centers the chuck plate, and by centering the bore of the chuck plate before the threaded portion is reached, insures that the threads engage easily and that the chuck plate may be readily drawn squarely against the face of the outer nose.

At the right hand of the apron within easy reach of the operator is a lever which controls the clutch and braking mechanism. An additional lever directly beneath the headstock is also attached to the same shaft on which the apron control lever is mounted. A slight upward motion of the lever throws in the clutch. A slight downward motion and the brake stops the lathe, or if the lathe has been ordered with reverse, the same downward motion of the control lever will reverse the direction of the spindle.

To prevent wearing the bed hollow near the head when the lathe is used for short work, all beds are made with chilled ways. The carriage is of good cast iron, but the bed is so much harder than the carriage that the wear comes on the carriage instead of the bed. Even though the carriage should become worn after several years' use, the bed will still retain its alignment.

The bed is of such depth and width as to give the greatest rigidity under heavy cuts. It is strongly braced internally by cross girths. The surfaces to which the lead screw bearings are fastened are planed to receive them; the bearing blocks are tongued into a groove planed in the bed, thus securing accurate and permanent alignment. The V's are large and the tops are rounded by grinding to prevent bruising. The surfaces between the V's are ground. At the rear end the bed is cut away to allow the overhang or quick removal of tailstock or turret. The feed rack is of high carbon steel, and, except on long beds, is in one piece. The horizontal and vertical surfaces of the inner side of the front shear are scraped bearings. This is used as a supplementary bearing for the carriage.

The carriage has an oil trough around the front and rear V's. This prevents the lubricant from running down over the apron. The carriage takes a right angled bearing on the inner horizontal and vertical surfaces of the bed directly in line with the tool thrust. This supplementary bearing greatly shortens the span of the carriage from the front V to the rear V, and gives a solid support to the bridge.

The tailstock is rigidly braced internally to withstand heavy cuts. It is so shaped that the compound rest can be swiveled to 90 degrees when using the tool on small diameters. It is clamped to the bed by locking bolts operated at the top of the barrel. The base is graduated for set-over. The spindle is of annealed tool steel. A plug clamp locks it in correct alignment and does away with the split barrel.

Quick change gears are of steel and are of such strength that feed changes can be made while the lathe is under a cut. The cone of gears is mounted between the walls of the bed directly under the headstock, solidly supported and away from all dirt and chips. There is no possible way for any of the bearings to twist or give when under a heavy cut. There are no gears with a great overhang. All studs are firmly supported.

The lead screw is of high carbon turned and ground stock, chased to a standard size. The lead screw passes through the double bevel gear sleeve and engages it by a key and spline. This key extends almost to the full length of the bevel gear sleeve, and the long bearing prevents any cramping action in the spline. The half-nuts are chased from the solid and then split. The threads of the lead screw are never in use except when the lathe is cutting threads. Lead screw has outside thrust at both ends opposed by high grade bronze washers.

INDICATING DIAL SCALE

AUTOMATIC DIAL INDICATING SCALES

The Toledo Scale Company, Toronto, have recently brought out a new industrial scale which is capable of weighing up to twelve thousand pounds. This scale as seen in the accompanying illustration has a large, easily read dial which is graduated up to two thousand pounds and when the heavier weights are to be weighed, instead of adding weights to the beam by hand, an automatic mechanism places the weights on the beam pan by the shifting of a lever. At the same time the weight in pounds which is to be added to the dial indication appears in large characters in a window on the dial face. This unit weight arrangement adds greatly to the sensitiveness of the scale, the dial indications reading to a small figure.

Tare beams are also provided and if for any reason hand weighing is desired it is accomplished by unhooking the dial mechanism, placing the weights in an auxiliary scale pan and proceeding as usual in hand weighing. The scale platform is not limited in any way to any one fixed dimension, but may readily be adapted to any condition likely to be encountered in practice. Industrial tracks may be readily used.

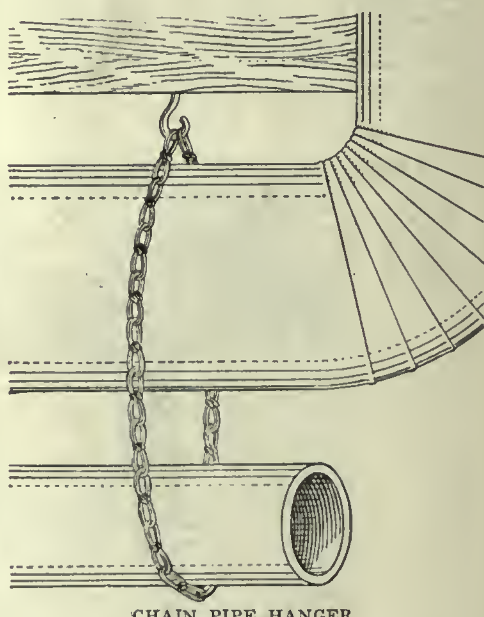
CHAIN FOR HANGING PIPE

The common method of supporting pipe has many difficulties which are very evident to any one who has had any experience in this line of work. The demand for better methods of hanging pipe has resulted in the development of a special chain for this purpose manufactured by the Cleveland Galvanizing Works, Cleveland, Ohio.

Bull Dog chain, as it is called, is more economical than other pipe hangers. It is furnished in reels from which the desired lengths can be cut as required. There is no waste which must be cut off as is the case with other hangers. This chain used as a pipe hanger is quickly and easily placed in position, the screw eye is screwed into the ceiling or beam above the pipe and the chain, having been cut to approximately the desired length, is looped around the pipe and both ends of the chain are slipped onto the hook of the screw eye as shown in the accompanying illustration. The steel from which these chains are made is the finest quality cold rolled steel wire. The links are formed with a special tie which cannot pull out.

It will be seen that the use of chain for hanging pipe offers several advantages. By moving the chain and simply tightening or loosening the screw eye the level of the pipe can be raised or lowered any desired distance. Larger adjustments can be made by drawing in or leaving out additional links. Where there is liability of considerable change being necessary it is advisable to make the chain several links longer than the desired length.

The extreme flexibility of the chain greatly facilitates the making of horizontal adjustment. This is found of great benefit when it is desired to shift the position of the pipe as it does away with the use of cross pieces to which the



CHAIN PIPE HANGER

hanger is fastened through the extreme flexibility of the chain allowing the pipe to be removed several inches without making any change in the length of the chain and without shifting the location of the screw eye.

TIMBER FOR AEROPLANES

By M. E.

WITHOUT going so far as to be in absolute agreement with those who believe that aeroplanes of the largest size can be best constructed almost entirely of timber, it is a safe prediction that the machines composing the air fleets of the future will continue to use a large percentage of wood.

Timber Resources Unclassified

Much, however, remains to be done before any real progress in this direction can be made as not only is our knowledge of the properties of timber from the standpoint of the engineer and aeroplane designer in the most elementary phase, but there are still only the vaguest kind of notions as to home and Empire sources in timber supplies of the right kind. While the Geological Survey has made a close investigation of the raw materials of the steel industry and supplies of ore, fuel and refractory materials from home sources have been carefully calculated and classified, the tabulation of timber as a raw material of industry has received little or no attention in Great Britain, and statistics dealing with the quantities of different classes of timber available, or even with the location of the varieties suitable for definite purposes are practically non-existent.

The needs of the war have accentuated our deficiencies in this respect. With a heavy call upon the steel and metal trade generally for materials for munitions and shipbuilding, it became necessary not merely to use timber for all purposes to which it has been commonly been applied, but to substitute it wherever possible for steel. None of the new demands for timber have been more important than that emanating from the aeroplane industry, and it is a tribute to our national facility to get out of a tight place and to muddle through somehow, that in the absence until recently of any department whose business it was to co-ordinate supplies with manufacturing requirements the needs of the industry should have been met as well as has been the case. We know that in Germany where the craze for organization has permeated the national fabric, and is sometimes a blight, although more generally a stimulus to industrial enterprise, that the timber resources of the Empire had, in the years before the war been tabulated, ticketed, and docketed with the utmost minuteness, and the available quantities of timber for many purposes, but particularly those required for aeroplane construction measured almost down to the square foot. The result was that the outbreak of war and the early revelation of the importance of the air arm found the enemy prepared with precise knowledge of the quantities and varieties of timher which could be provided for aeroplane work, while we in this countrv were almost in the dark, hoping and believing that supplies could be obtained by relying very largely on supplies from overseas which, with the constant depletion of merchant tonnage became even more and more difficult to obtain. It was only indeed at the eleventh hour, and under the pressure of circumstances that we began to draw on our resources and discovered the general ignorance which prevailed as to extent and character.

The want of precise knowledge of the mechanical properties of timber is, altogether apart from the question of supplies, one reason why the engineer has been inclined to shut timber wherever possible out of his specifications in favor of steel, or any other metals, the investigation of mechanical properties of which has attracted a thousand investigators and has resulted in spite of gaps of knowledge in certain directions in the production of formulae which have enabled the engineer to use the material with an assurance of behaviour under particular conditions of service. In the case of timber he either rejects it altogether or employs factors of safety on the very high side. The need of investigating the mechanical properties of a neglected material is the more necessary when it is remembered how extensive is th field to be covered. Mr. Barling did not exaggerate the case when he reminded the Aeronautical Society in his recent contribution that whereas here may be about 100 metals and their alloys in fairly general use, there are at least 1,000 different kinds of wood on the commercial market.

Little Research Work Done

During recent years, except perhaps in Germany, there has been little or no research work in the engineering properties of timber worthy of the name. It is necessary to go back for nearly a century to find the records of any exhaustive work on the subject. Wertheim and his colleague Chavandier—both Frenchmen—examined the mechanical properties of European timber in detail, and the main conclusions at which they arrived, and which have been confirmed by repeat experiments, form the basis of our present knowledge of the mechanical properties of engineering timber. One broad conclusion emerges from the mass of experiments then conducted; it is that the law of strength being proportional to density holds good over a very wide range if account be taken of the wetness. Wertheim and Chavandier went into this factor somewhat fully, and their work showed quite clearly the decline of density with dryness, and the associated rise of elastic modulus, and the natural drop in elongation as the percentage of wetness is diminished.

Effect of Moisture

There are critical points affecting these properties which need to be carefully investigated, but it would seem that the limiting range to give maximum tenacity is 10 per cent. of moisture. With higher percentages there is a fall in tenacity, and with increased dryness brittleness is induced. On the effect of distance from the centre of tree on mechanical properties, Wertheim found that these increased in regular ratio in passing from the centre toward the circumference. The gain in strength varies with different timber; the increase with radius is perhaps at its highest in the coniferous woods, while in the case of oak and birch the mechanical properties are at their maximum in specimens taken from a point at about one-third of the outside radius, while in beech much depends on the age of the tree from which the test piece has been taken. Then there is the effect of height of tree, and as might be anticipated there is a gradual decline in mechanical properties in passing upwards from the base. The influence of soil and situation was also investigated by these early workers.

General Applications Possible

It is quite obvious, however, that while some general applications can be made from these broad conclusions, much recent knowledge of the properties of timbers, and particularly those used in aeroplane construction have had to be derived from a process of trial and error, and in the midst of the distraction of a great war and an intense pressure for delivery of machines. The trouble is that there are great practical difficulties arising from the material difference in behaviour of woods, depending on the direction in which the twist is made, and although perhaps the figure of variation, 600 per cent. for the same timber, given by Prof. Groom is rather a bogey maximum than anything else, it refers to a real difficulty which has confronted the industry. Additional knowledge is also required of the influence of the time factor as well as resistance to shock, for which it is necessary to devise a sound test.

One difficulty at the present time is that as was indicated by a recent discussion before the Aeronautical Society, a number of investigators are taking up the subject, but there is an obvious tendency to carry on the work in a series of watertight compartments. The existence of war conditions imposes the need of secrecy, and for this reason no reference has been made in this contribution to developments which are now in progress or to certain facts which are the direct outcome of experience. It is desired, however, to voice the demand which has been made for a co-ordinated scheme of state-aided research on the mechanical properties of an engineering material for which during the next few years there will, with the development of the aeroplane industry, be an enormous demand. It is also necessary to have a complete survey and classification of all the home grown timber applicable to the needs of the aircraft manufacturer. These are among the fundamental requirements of air industry and they are dominant needs of a nation which must, at all costs, secure the command of the air.

Using B. C. Timber.—Adaptability of British Columbia spruce for aeroplane work is shown by the fact that shipments east in one month now double the total from August, 1914, to January, 1918.

A Fortune in Peterboro ! ! !

THE Peterboro *Examiner* has a reporter who is out to lift the load of debt off that city. He's probably heard the ratepayers kicking about taxes and the thing laid hold of him. He longed to be another Horatius at the bridge and sweep back the tax rate. So one day he heard of a pile of old tin cans on the outskirts of the city and the idea struck him square between the optics.

He hustled back to the office, stripped for action, and put the following past the editor. Just in passing it might be mentioned that the heading for the article was even stronger, and said: "A Fortune at the Incinerator—Scrap Tin Has Accumulated Ever Since the Building Was Opened." But here's the story:—

> "The city has acquired a little fortune from the cans and tinware which has been taken from the garbage at the incinerator. Tin cans, stove pipes, tin pots and pans, old boilers and anything made from tin can be seen at this heap at the rear of the incinerator. The tinware resembles a railway embankment, and extends from the incinerator nearly to the railroad tracks. As scrap tin has risen enormously in value the city should be able to realize a handsome sum from its sale. The pile has accumulated since the incinerator was established, none of it having been removed. Before the refuse is dumped into the holes leading to the fire the tinware is picked from it and loaded on wheelbarrows and taken to the tin dump. The tin is all on city property, but it will soon extend into other property unless it is soon removed or is built pyramid-like above the incinerator building."

Now this little yarn might have caused a bit of joy in the heart of Peterboro. The only thing wrong with it is that it's a mile and a quarter wide of the facts. We don't doubt for one minute that Peterboro has a dandy heap of tin cans, but we doubt very much if they will ever make a fortune out of them. If the *Examiner* reporter has any other opinion than that let him start and pick up the cans and sell them. His pay envelope would look like a bloomin' fortune by comparison to his returns from scrap tin. As a matter of fact scrap tin is not high. It is low now, and has been for some time. It sells to-day at $12 per ton and that price is for scrap tin plate. Old prices used to run up as high as $24 per ton. In those days the big demand was for the making of tetrachloride for weighting silk. That industry, which was largely centred in France, has been seriously interfered with on account of the war.

As a matter of fact tin cans are worth nothing at all. "I wouldn't say thank you for a whole train load of them," stated the largest scrap dealer in Toronto this morning when the question was asked by this paper.

So there's Peterboro's fortune all shot to pieces—a tin can tied to it, so to speak.

Bill Haywood in Jail Now

BIG Bill Haywood, leader of the I.W.W. in United States, has been sent to prison for twenty years, and a stiff fine has been imposed as well. Other lesser lights have gone down for lesser terms. The peculiar thing is that Haywood and those associated with him have been able to get away with their rubbish as long as they have and remain outside the prison gates. Of course, Haywood has been jailed a good many times. It is no new sensation to him to look at current events from behind the bars. But this time it looks as though Bill were in for a good long look, and by the time twenty years turn over there won't be much rumpus left in the carcass of said Bill.

Haywood is well known in Western Canada. In fact the Crow's Nest Pass district in the south of British Columbia, the towns along the foothills of the Rockies in Alberta, and all the district where socialism runs rampant, were the real stamping ground for Haywood. He's not altogether a pleasant chap to gaze upon. He's big, well developed, but has one optic that is badly damaged. But to meet the man off the stump is to get a shock. He is not the lawless tub-thumper any more. His voice is mild if anything, and he betrays nothing of the bravado or the apostle of blood and thunder that has made him famous. He accepts arrest in the very best spirit. In fact it would almost seem that he did so with a feeling of pity for the police, the law makers, and all and sundry who had anything to do with skidding him toward the cooler.

But allowing for all that, he's a better resident in jail than outside it. The one question that has never been satisfactorily answered is, "How did you get away with it all, Bill?" For certain it is that had the small fry of the land taken it upon themselves to make such a stink as Bill stirred up, the law would have had them as soon as the sheriff had time to pull on his knee boots and fasten his office tag on the lapel of his coat.

Pleasure Driving on Sunday

THE automobile owners of Canada did not stop driving their cars on Sunday last, although a request had been made to them asking for such action. Gasoline is urgently needed in very large quantities for military operations, and there are many essential purposes in this country now consuming a large amount of this fuel.

In United States the residents have shown their determination in war matters again. They have stopped Sunday driving. In fact one New York man met with a deluge of eggs that were hatched on last year's bushes because he persisted in driving for pleasure on Sunday.

Is it more necessary that Canadians shall have a good time on Sunday than that there shall be plenty of gasoline for military operations? It begins to look as though that were the view some of them took of the matter.

Get the picture in your mind of the Canadian boy who has been at the front for years. He's been in the trenches. He's gone over the top. He's been wounded, wet, tired and sick, and yet he stays with it.

And yet when the request is made to cut out Sunday driving at home for pleasure, you won't do it. You're some patriot, aren't you?

FLOATING war loans free of government taxation is wrong—in fact it is indefensible. It puts the government into immediate and unfair competition with investment money for industrial purposes. It's a bang in the eye for that good old principle of equal rights to all and special privileges to none.

Radical Change in Ship Construction Methods

ANOTHER application of the electric welding outfit is in welding ship hulls. A ship has been recently built in Great Britain in which rivetting has been largely dispensed with, and the joints made by electro-welding.

This opens up a field of wide possibilities once the difficulties of initial cost of electrodes and plant are overcome. In point of strength there should be no difficulty for the strength of a rivetted joint seldom exceeds 70% of the solid, and good welding can be at least as strong. For the outer skin of the ship, where plates overlap each other, this method of making a joint should be easier and better than rivetting and it dispenses with caulking. For plates on tank tops, it should be a quick and serviceable method, but for joining framing and intercostals, it would hardly seem as good as rivetting, the extra stiffening of the rivet heads being lost. In many of the large passenger ships of recent building, the rivet heads in the upper courses of plates, as high as the hurricane deck, have been left full as this materially decreases vibration by stiffening the plate.

For watertight bulkheads this method is very suitable, and wherever it can be employed it eliminates the marking off, boring and rivetting of plates which means an immense saving of labor, and it also saves the rough usage of the plates occasioned in drifting holes into alignment. It will be interesting to watch the further development of this latest improvement on our old methods.

We'll Need Help On This

AN order has been issued by Rear Admiral Wood, commanding the Boston naval district, the drift of which is that all letters sent out or official documents must bear the name of the writer typed as well as in ink.

The reason is plain. The official has come to recognize that the average signature of those who write letters or fill in documents is not legible.

In business correspondence the plain blind signature in ink has always been a hard hurdle to take. There are some men who seem determined that they shall write their names in such a way that the work of deciphering them will be a problem that will make lawyers dizzy and ordinary laymen clean, stark, staring mad.

There is on our desk at this moment a letter from some gent in Winnipeg. His paper is fine and there's a picture of a building on top. The whole thing smacks of quarter-cut oak, plate glass and office hours from 10 to 3.30.

And what he says isn't half bad either. He canters along at an easy style and performs like a chap who would buy silk hose and chocolates for his stenographer at Christmas.

But when his stenog. gets through at the end and shoves the paper across for his nibs to operate upon—good night!

He started strong and ended stronger. It looks like Creatore leading a crescendo or the head trombone player for Sousa in action up to his knees.

It may be that this Winnipeg friend of ours has a great big wad in the bank and is scared stiff that some slippery person will forge his name and drive a bung hole into his saving. If that's correct he's surely bamboozled all the check-raisers and forgers that ever camped west of the Great Lakes.

He's a dandy. No doubt he was a dandy at a run-hop-step-jump when he was young, and, we'll bet our meal ticket that he could stand on his head before he was six years old.

Our big problem just now is that we want to write this chap in answer to his "favor of the 27th," etc., but whether to send it to the street cleaning department, the Winnipeg bug house or the cattle yards—we'll be durned if we know what to do.

When you sign your name to anything, for the love of Mike, don't try to do a skirt dance or play the mouth organ at the same moment.

Mother's Holidays

FATHER had the rinky-kink, or some disease like that—he said it made him feel at times as dippy as a bat. He couldn't speed up with his work, he couldn't write or think—in fact, his whole anatomy was somewhat on the blink.

The doc. had told him to depart unto some mountain stream, where he could smoke his black cigars and meditate and dream.

So mother packed a trunk of duds, and with pity in her voice she bade a sobbing farewell to the husband of her choice.

Then Mary Ellen had the dumps, she couldn't go to sleep, she feared she might at any time collapse into a heap—the social season was a grind, it had been one grand slam, it left her with a broken heart and a busted diaphragm.

A specialist she went to see, he looked her in the eye, and told her to vamoose at once or camp at home and die.

So Mary Ellen had to have a trunk or two of frocks, to flounder by the sad sea waves or squat upon the rocks. So mother had another spell, it lasted quite a while, and bustled Mary Ellen off in stunningest of style.

Then Thomas Henry had a kink, he was the son and heir, and sawbones told him to depart and quit his work and care.

His summer rags were dusted off, his cream pants creased just so—and mother hustled round like sin to make him fit to go. At last he went to some resort that cost three bones a day, and mother hoped that he would be much strengthened by the stay.

And then it came to mother's turn when all the rest had fled—she didn't go away at all, but stayed at home instead.

She tended to the garden plot, sprayed water on the lawn, she worked until the sun went out and was 'round again at dawn.

She canned a hundred jars of fruit, made fifteen kinds of pickles, while those of poorer grit than she blew in the family nickels.—ARK.

ARE YOU ENTRENCHED?

MARKET DEVELOPMENTS

Business Moving in A Big Way In Canada

Several Buyers Have Left For Producing Points—Deliveries Have Been Made From Shops on 9.2 Orders—Ottawa's Newest Order Causes no Stir in Iron or Steel Market

CANADIAN buyers are "over the line" in goodly numbers this week. In some cases the quest is machine tools and supplies, in others it is the making of some better arrangement on the part of jobbers for the securing of mill deliveries on sheets, etc. As a matter of fact, business in Canada that has to do with the turning of wheels is good, and is going to continue so for some time to come.

There are big business houses in Montreal and Toronto that right now would be glad were Ottawa to rule out some of the business that is passing through their hands. They fear that the tremendous orders that are being placed will deplete their warehouse stocks to the point of exhaustion, and they realize that the chances of filling their floors again are very poor.

Some of the concerns that took on American 9.2 orders recently have already made their first deliveries. This is record time, and it was possible because the firms had been on the large shells before, and had simply to revert to it after finishing six-inch orders. A large amount of fuse orders are being turned out here on Washington specifications. The Canadian War Mission at the American capital is confident of having the shops of Canada kept working to capacity on good business.

The order from Ottawa that the War Trade Board would control the supply of iron and steel in Canada, and direct its disposition, is not new or alarming, and the trade is quite willing to accept any ruling along this line. As a matter of fact the steel industry and the pig iron, too, has been under the direction of Ottawa for some time. They have, according to their own statement, been working "in close touch with the authorities," which is another way of saying the same thing.

Tin has taken a rather spectacular drop. A few weeks ago it was heading for the $1.50 mark, and $1.25 was the trading point for some time. Sales were made this week around the $1 mark, and dealers seem to incline to the view that a lower level may be arrived at now that the decline has set in. They claim that deliveries are freer. As a matter of fact the price of tin has been largely a fictitious one, and manipulation rather than absolute circumstances has had much to do with the meteoric career of the selling point.

Reports from various foundry centres in the Dominion indicate that plants that are on war work or work that is considered necessary to the upkeeping of agricultural production are getting a fair supply of pig and scrap iron at current prices. On the other hand shops that have no rating in the eyes of the government are having a hard time of it in getting enough pig iron. They are using a mixture in which scrap figures on a fifty-fifty basis, and this is considered by experts to be a dangerous practice, as it is almost impossible to get results at that point unless the scrap pile has been well analyzed and sorted beforehand.

PRODUCTION CAN'T SIZE UP TO PROGRAM OF THE U.S. WAR BOARD

Special to CANADIAN MACHINERY.

PITTSBURGH, Pa., Sept. 12.—The constant reiteration by the War Industries Board of Statements of the amount of steel required and the amount likely to be made, showing a large deficit, must not be regarded as suggesting that there is any divergence of view between the board and the steel makers. The latter are fully convinced, and they have been ever since April or May. As noted in last report the board places the requirements for the half-year at not less than 23,000,000 tons, with the list constantly being added to, while it named the prospective production at 17,000,000 tons. That, of course, was on the conservative side. From all appearances at this centre of production, where such matters can be judged closely, prospects are that production will be between 18,000,000 and 19,000,000 tons, and it is even possible that the higher figure may, if circumstances prove especially favorable, be exceeded.

The shortage of steel is, as a matter of fact, reflected by the actual conditions in the steel trade as they may readily be observed, the mills being able to furnish at the present time very little steel for purposes not entitled to a high grade of precedence. The supply reaches farther down the list of sequences in some descriptions of steel than in others, and farther with some mills than with others making the same class of product, but there is an effort, of course, to iron out these irregularities.

The System of Working

Before making specific reference to the position of different mills it may be well to review briefly the system under which pig iron and steel products are distributed. First, priorities and preferences should be defined. A priority, or priority order, is simply a regular order, such as obtain in the trade at all times, but with a sequence designated. A preference, on the other hand, is simply a purpose. The "preference list" is a list of purposes, in sequence, for which material would be used if furnished. Originally priorities were given to orders only by the War Industries Board, a separate action being taken for each order. By the new system, established in July, "automatic priority" is provided, the buyer attaching the priority number to the order as he places it, being guided by specific instructions, his action being subject to review by the War Industries Board.

Learning the A B C

Priorities are divided into three general classes, AA, A and B, with sub-ority. Still lower come the preferences, over A-1, and B-7 over B-8, the last named being the lowest degree of priority. Still worer comes the preferences. No producer is permitted to ship for a mere preference purpose except he has provided for the filling of all priority orders by the respective dates attached to them, or to fill a given priority order until he has provided for all priority orders of a higher rating. The preferences are designated generally as Class C. There is a final class, Class D, which is steel (or pig iron) which would go for a purpose not entitled to preference. It can only be furnished when everything else has been taken care of, and a permit for each shipment over five tons must be secured from the Director of Steel Supply. There is a blanket permit for lots of five tons and under, but with the limitation that the producer must report all such shipments monthly with a certification of belief that they were "in the public interest." In existing circumstances Class D is practically a dead letter, but it is useful as rounding out the nomenclature and providing for contingencies.

A confused impression may result from the fact that purposes for which priority orders are issued are named on the preference list, which includes all war work, such as shells, aircraft, ships, etc. In speaking of deliveries "on the preference list" one really means not the whole preference list, but that which remains after the preference purposes that are also entitled to priority have had their priority ratings assigned them. whereby they are removed from the preference list, for actual practice, and given a higher place.

To get down to actual fact, there are some mills so situated at present that they can take care only of priorities AA and A, having no steel to spare even for Class B-1. Other mills are providing for all priorities in full down to and including B-3, but when they get to B-4 the supply runs out, there being less than enough to cover all B-4 orders. As that is the degree assigned to steel for replacement in jobbers' stocks of material shipped under priorities and preferences it is an important and large class. Such mills scheduled jobbers' August quotas but will not complete shipments for a few weeks yet, the September quotas being correspondingly delayed. There are few mills that have steel left after providing for all priorities, down to B-8.

Showing a Deficit

Thus it will be seen that few mills are able to ship steel on mere preference, and yet the preference purposes left after priorities are subtracted represent a large tonnage, and they are included in the War Industries Board's estimate of 23,000,000 net tons of finished rolled steel required for the present half year. In other words, the position of the steel mills, as disclosed by actual inspection of the classes of shipments they are making and can make in the next few weeks is in strict accord with the War Industries Board's estimates, showing a large deficit of steel.

While the deficit has been increasing steadily it may possibly be reduced in the next three or four months, because at the present time railroad requirements are exceptionally heavy. As the railroads began to function very well in the Spring, after their decided breakdown in the Winter, it was feasible to postpone their rehabilitation, against another Winter, in favor of more pressing steel requirements, but now this work must be rushed, though only, presumably, for say three months. Rail production is now very heavy in consequence, and the building of the 100,000 freight cars ordered a few months ago is being pushed, with prospects that all, or very nearly all, will be completed before the end of the year. This is despite the fact that large orders for 30-ton standard gauge cars, and for narrow gauge cars have lately been placed for the A. E. F., with many more required, and doubtless figuring in the 2,000,000 ton estimate. Some of these will have to go over into the new year.

Pig Iron Is Scarce

Production of pig iron in August was at the rate of 40,300,000 tons a year, against rates of 40,700,000 tons in July, 40,800,000 tons in June and 40,900,000 tons in May. The curtailment in the midsummer months, with their high humidity affecting the output of the individual furnace, was less than usually occurs. Considerably larger production is in prospect. The weather will be more favorable. Some furnaces will probaly be taken off ferromanganese and spiegeleisen, which are not scarce, and put back on pig iron, which is extremely scarce. The Fuel Administration is making strenuous efforts to have better coke made, as some furnaces have complained of quality and probably it will also be possible to make somewhat more coke.

Using the machinery of the Bureau of the Census the War Industries Board has undertaken an inventory of all the steel in the hands of manufacturing consumers. a questionnaire being sent out to about 40,000. Whether much of the steel can be utilized is a question on account of the thousands of forms in which it exists. Some time ago jobbers were required to report their stocks. Possibly some jobbing orders will be thrown to manufacturing consumers to be filled out of their stocks.

POINTS IN WEEK'S MARKETING NOTES

Toronto firms taking on 9.2 American contracts have begun to make deliveries.

A No. 2 fuse is being made in a Canadian plant now. The manufacture of fuse had been discontinued here for some time.

Steel jobbers in Canada are handling such large volumes of business that they have difficulty in replenishing warehouse stocks.

Canadian firms have many buyers at U.S. points at present looking for machinery with any possible promise of early delivery.

Scrap business is brisk at U. S. points and correspondingly poor in Canada.

The price of tin has dropped to $1.05. It has been selling in recent weeks as high as $1.35. The values were not real and figures below the dollar mark may be looked for. Pre-war prices used to run around 30 cents.

The War Industries Board of the United States places the requirements at 23,000,000 tons of steel for last half of 1918, while the best the furnaces can posibly do is 17,000,000 tons.

Large quantities of rails are now being rolled by U. S. mills.

More U. S. blast furnaces are to be turned over to pig iron production.

A THIRSTY JOB

WANDERING around the Toronto Exhibition grounds is a thirsty job. To be sure there are rows after rows where one can take his thirst and get it rubbed over with pink lemonade, or if the worst comes to the worst a stop can be made and the victim, horse fashion, can unhook his nose bag and gurgle over one of those ultra-sanitary fountains that sputter and spit at intervals all over the premises.

But all said and done, sight seeing and collecting samples of pressed hay in the form of breakfast food's a durn thirsty job.

And so it happened that a brawly Scot who wandered past the exhibit of the Canada Machinery Corporation had his eye pulled up on a glass that was cavorting up and down on the shaper that was operating there. The glass was there to show the rigidity of the machine and the evenness with which it operated.

The Scot watched the operation, noticed that the glass was not attacked by any one around the premises. He quietly nudged one of the C.M.C. men and poured into his ear:

"If yon glass wur full of Scotch whusky you'd hae to fill it oft'ner."

AUTO SHOP CAPACITY TURNS TO WAR ORDERS

Business Still on Very Large Scale—Big Government Undertaking Established in France

Special to CANADIAN MACHINERY.

NEW YORK, Sept. 12th.—Machinery makers have received several large contracts from ordnance shops and shell manufacturers in the last week. Large contracts are also pending for machines to be used in the manufacture of power equipment. Manufacturers supplying aircraft builders and motor manufacturers have received large orders within the last few days. Ship builders continue to place supplementary contracts and numerous small orders are being placed by automobile manufacturers, all of whom are preparing to use the full capacity of their shops on war work. Some of the larger makers of automobiles have placed heavy orders for shop equipment.

Big Plant in France

The Ordnance Bureau of the War Department has placed several million dollars' worth of machinery included in the recent estimates of $12,000,000 to $15,000,000 to be expended in equipping the great gun-relining plant in France. Included in the more recent purchases are monster planers, gun boring lathes and several large grinding machines; one of the latter to cost $100,000 has been placed with a New England manufacturer. The Amalgamated Machinery Corpp., of Chicago, is to construct a monster concrete metal planing machine having a bed 500 feet in length for planing the beds of the great gun-boring lathes to ship to France. These gun-boring lathes have a swing of 102 inches and are 85 to 200 feet in length; forty of these machines have been ordered by the Ordnance Bureau. The same company has large orders from other ordnance makers, including 186 shell making machines for the Neville Island Ordnance plant. To expedite work, the company is now building an addition 75 by 300 feet to one of its shops in which it will build planing machines. The Midvale Steel & Ordnance Co. has also placed additional orders for tools for its 16-inch howitzer plant at Nicetown, Pa.

List of 1,000 Tools

The Baldwin Locomotive Works put out inquiries for over 1,000 machine tools and 80 travelling cranes last week, but will not close contracts until Government approval has been obtained for the building of the plant as well as for the placing of orders for equipment.

The Bethlehem Shipbuilding Corp. continues to buy tools for its new yard at Alameda, Cal. The Newport News Shipbuilding and Drydock Co. and the Barber Asphalt Paving Co., Philadelphia, have completed purchases of machinery for the making of marine boilers. Ship yards in China that have received orders for ships from the United States Shipping Board have placed orders for twelve punching machines in this country. The Federal Shipbuilding Co. has launched another 9,600-ton Liberty ship and is still buying machine tools and other equipment. The Sun Shipbuilding Co., Chester, Pa., has bought more equipment for its repair shops. The American Shipbuilding Co. has closed on some of the tools in its recent list, including a 42-inch x 28 foot heavy duty engine lathe.

The United States Government is to purchase additional machinery for shipment to France, including eight turret lathes for the Engineer Depot. The Navy Department is inquiring for lathes, planers, turret lathes and pipe machines for the Puget Sound Navy Yard and for six turret lathes for the Boston Navy Yard. Bids will be received September 24th on a long list of tools for the Washington Navy Yard. A contract for a repair shop at the Brooklyn Navy Yard has been awarded to the Austin Co., Philadelphia, by the Navy Department. The same contractors will also build a munition plant at St. Louis for the Laclede Gas Co., which has undertaken the work for the Government; 1,500 tons of structural steel will be used. The plant which the Ordnance Department will build at Long Island City is temporarily held in abeyance; the estimated cost is $400,000. For another Government plant at Fairmount, West Virginia, inquiries have been put out for a bending roll and punching machines. Henry Ford & Son are receiving bids on machinery for the Hamilton, Ohio, tractor plant and it is understood that 400 machine tools will be purchased. A large lot of milling machines are wanted for the manufacture of bayonets.

PIG IRON DELIVERIES ARE FOR WAR WORKING PLANTS ENTIRELY

THE war news from the western front is closely coupled with the progress of the industrial world. As the enemy is driven back the efforts of the workers at home are redoubled to keep up the pressure. The makers of wire were cut 25 per cent. in raw material lately, and the chances are that they will get another reduction.

Whether there are good chances of success or not, the fact remains that makers of pig iron at many U. S. points are agitating for a higher price for their produce. They claim there is no money in the business at present rates. Although the production figures are showing an increase, they don't begin to keep pace with the demands that are made on the furnaces. Reports from U. S. centres are as follows:

Pittsburgh.—The demand for a higher price for pig iron is taking form here. Some of the owners of blast furnaces claim that they cannot go ahead and do business at present values. In one case it is reported that one firm is not buying more ore, and that after present stocks are exhausted the Government will be asked to come in and operate the business, and the owners go so far as to state that they will not ask for any profit on their business. They point by way of justification to higher wages, increases in freight rates and other higher charges that are rapidly coming to the fore.

Producers go so far as to claim that were higher prices granted the output of the furnaces could be increased any way from 50 to 70 per cent.

Philadelphia.—There has been some selling done for first half 1919 iron, but the volume of trade has not been as large as in other years. A bit of complaint is heard because some consumers get immediate shipment for certain work, while at the time they have stock in their yards.

Buffalo.—Very little business is being booked here. The trade seems to be thoroughly convinced that it is no use taking on business unless it is sanctioned by the Government, in which case they say the allocations will take care of the output of the furnaces.

Cleveland.—Many of the users here report that they are having difficulty in securing supplies of foundry iron, for the reason that so many of the stacks have been at work on basic. Certain northern producers are still booking orders for delivery in 1919 to war shops.

Chicago.—Melters here do not seem to consider that it is necessary to make contracts under the present system. Bookings made some time ago are being seriously interfered with by allocations made by the War Board on work that they consider of prior importance.

Cincinnati.—There has been a realignment of contracts in this district, made necessary by some of the shops that were not on essential contracts turning over to the manufacture of machine tool castings for war shops. There is very little trading between shops in supplies, as the policy of each place seems to be to conserve every pound in the yard.

St. Louis.—Pig iron is delivered in fair quantities to shops working on Government contracts. In fact there is no complaint from them. Stove manufacturers have gone heavily into the scrap market, but this source is getting to be as uncertain as the pig. This industry has not yet been given a rating.

CANADIANS DOING A LARGE BUSINESS

Working to Capacity Seems to Describe Present Activities in Many Directions

TORONTO.— Machinery business in Canada is still moving in large figures. There is quite an invasion going on now—a peaceful one—of United States machine tool centres, and the invading forces consist of dealers in machine tools from this side of the border. Not only so but dealers in sheets and plates are on the other side of the line in large numbers, as well as those who are selling high speed goods. They take everything they can secure on this side of the line, and want all they can get on the other. The Canadian War Mission at Washington is trying to keep closely in touch with the capacity of Canadian plants. The idea seems to be in United States to get production where it can be secured the quickest. There is not much encouragement given to opening up new munition factories now. There are a large number of them in existence, and often they are able to enlarge and increase output much more readily than by the opening of new plants.

Some of the contractors who are taking on 9.2 contracts for the Washington Government have been able to make their first deliveries. The manufacture of fuse (No. 2) is also being proceeded with again on U. S. order. The making of fuses had been discontinued in this country for some time, but is being revived on a fairly large scale.

In Narrow Limits

Jobbers in Canada are working in limits that are so narrow that they are impossible. There is a shortage of sheets in this country now that has not been known before in some time, and prices are coming along in sympathy with the situation, an advance of one cent per pound being noticed already. Several Canadian dealers are off to United States mill points now to see what they can do to protect their warehousing business. They have been working under the U. S. pledge in regard to war work for a time, but they are at a point now where they are getting very few deliveries from the rollers. As a matter of fact one of the largest dealers in the Dominion stated to CANADIAN MACHINERY to-day: "I wish some of the business that we put through would be shut down on by the authorities at Ottawa. If things keep on as they are at present, and if our chances for replacement are no better than at present, we are going to find ourselves unable to supply the customers that are working on real essential war contracts."

Priorities are demanded by some of the U. S. business on all orders coming to Canada, while as a matter of fact priorities are not required until they come to .120 sheets. Ottawa has a habit of telling dealers to get their customers to use thinner material, but the trouble is that this cannot be secured. Jobbers get a B-4 rating in many cases, and deliveries to that standing are none too good. Neither is there much prospect of better treatment in the immediate future.

Premier galvanized sheets are quoted to-day at $10.70 (28), while 10¾ oz. have advanced to $11. Black sheets are still selling at 8¼ c, but the chances seem to be against that figure lasting for much longer.

Business Quiet in Scrap

Conditions are much different here and at U. S. points regarding the scrap metal trade. Across the line there is a keen demand for almost every kind of material, and maximum prices are being paid with the commissions added. In this country the scrap metal market is suffering from fatigue or something closely akin to it. There is just a fair volume of trade moving, in some cases dealers buying offerings to protect their credit and market rather than from any desire to take the material into their yards with prospects for a quick sale.

Brisk Demand Now

Dealers in high speed and carbon tools are selling more to-day than they have been doing for some time past, in fact the sky seems to be the limit in some cases. Especially cutters and reamers are wanted. There has been no change in lists recently.

There has been an unusual call in a large way for tools for U. S. shops. In some cases auto plants have been ordered to get over on war work, and the making of the change means a large supply of special purpose machinery. And behind it all the element of haste always has to be taken into consideration.

Tin Drops Down

The trade has been watching for the price of tin to blow up for some days, and quotations out now show that it is nearing the $1 per pound mark. Although it is quoted at $1.05 there have been sales made at a lower figure. As a matter of fact the whole situation in regard to tin has been highly fictitious and unreal. Thirty cents a pound used to be a fair mark, and if a few weeks ago a person had wanted to buy in futures, the price would easily have run up to $1.50. The whole supply comes through England, and there has been more manipulation than real cause behind the increases. Deliveries are freer now and larger quantities are coming in. It would occasion no particular surprise were it to come to a more reasonable level yet in the near future.

FEW APPRENTICES AS MOLDERS; PROBLEMS OF THE FOUNDRY TRADE

FOUNDRY men are having problems of their own at present. They are in many cases short of material and there are not enough molders to go around. Scrap has been bought in larger quantities than usual, in fact in some cases a mixture is used in which almost fifty per cent. is scrap. To go past the 40 per cent. mark was usually considered dangerous. In fact for particular work good care has to be taken in selecting scrap at 40 per cent. mixture.

A good big supply of pig iron would be a very acceptable thing just now to the Canadian foundry trade, but instead of becoming more plentiful the supply of pig becomes more scarce, especially for plants that are not on war work. In fact it is simply a case of "old connections" that keeps some of the non-essential concerns supplied to the point of operation. There are cases where the War Trade Board at Ottawa has informed users that they cannot have a supply, and it looks as though there would be more of this sort of business.

Molders Are Scarce

Foundrymen have stated most persistently recently that the supply of molders was running out in Canada. This may be so, or it may not, but certain it is that if molders are still in the land they are not all in the molding shops. Not long ago a prominent manufacturer expressed the opinion to this paper that it was only a matter of time until the molding business passed into the hands of the foreigners.

What Foundrymen Say

Apparently the shops of the East are in no better condition than those of Ontario or the West. For instance, C. A. Lushy, secretary-treasurer of the Amherst Foundry Co., Amherst, N.S., states that, "We have considerable difficulty in getting pig iron but as we have been supplying a considerable amount of goods for the Reconstruction Committee at Halifax, which is government work, and we have also been supplying goods for use in barracks and different plants throughout the country which are manufacturing munitions, the government has allowed us to have a small percentage of pig iron compared to our normal requirements. We are using more scrap than usual and are getting so far good results. We use about 40 per cent. of scrap iron, but do not think that we could use a higher percentage without interfering with the quality of our goods."

The supply of molders is sufficient for the present, as this firm has, according to their statement, "a sufficient number of moulders to keep our foundry running under present conditions, but if we could secure all the pig iron that we could use we would require a large number of moulders above those that we now have. In regard to apprentices, we usually are able to get all that we require and we should think there should be no difficulty in finding apprentices for the moulding trade as moulders, as a class, are very well paid men. We, of course, in this part of the country, employ very little foreign labor, as our foreign population here is very small."

Another Maritime Report

T. McAvity & Sons, Ltd., of St. John, N.B., is another well known firm. They are able to secure supplies of raw material, being largely engaged on war work at present. In regard to the situation with molders G. C. McAvity states, "I fully agree that there is a growing

shortage of molders, although in this section of the country we have not yet seen very much of the foreign element as moulders, although it has been practically impossible to get any young men to serve as apprentices, which, of course, we think is more or less due to the fact that they can receive a great deal more money to-day from common laborers' work, not appreciating the future."

In Brantford Shops

Goold, Shapley & Muir Co., Ltd., Brantford, are using a 40 per cent. scrap mixture and are securing good results, working very largely just now on agricultural tractors. Regarding the number of molders, W. H. Whitaker, of the company, says that, "We have some difficulty in the securing of sufficient molders and usually our floors are running three and four behind on account of the scarcity of men. We have not yet employed foreigners in this department of our work as molders. There is some truth in the statement that few young men are offering as apprentices to the molder's trade."

In other Brantford shops a decided shortage of pig iron is reported, although a fair amount of sorted scrap is on hand and is being freely drawn from. In regard to apprentices, shops have few in the molding department. In fact there is a shortage in all trades. An official of the Waterous Engine Works Co. stated to this paper that, "As far as our experience has been, it is quite true there are no apprentices. Practically no apprentices are offering for any part of our factory."

RENEWING ORDERS STARTS NEW DRIVE

And Machine Tool Trade In Montreal Is Brisk as a Result

MONTREAL, Que., Sept. 9, 1918.—The influencing factor on the present industrial situation is the apparent scarcity of many lines of material required for maximum operations. The feature of Government control of nearly all the essentials of production eliminates the possibility of any pronounced fluctuations in price quotations, so that the market is one of available supply rather than that of supply and demand, the controlling factor of prices in normal times. The great problem at present is that of supplying the wants of the shipbuilders and carbuilders, the output of plates being inadequate to the trade requirements.

Uncertainty In Steel

The general situation throughout the steel industry is apparently identical with that prevailing for several months back, as the market is one virtually controlled by the War Trade Boards of this country and the States. With few exceptions the production of steel at the present time is devoted exclusively to war essentials, either directly or indirectly. In the opinion of some dealers, however, it is believed that the output of the mills is in excess of the actual requirements, as in some instances it is thought that specifications for steel are greater than the needs, the object, no doubt, being to make certain that the available supply will tend to a surplus rather than a shortage. This condition, it is felt, will eventually mean that stocks will be accumulated which will tend to develop a weaker market. Local warehouses are practically depleted of steel material suitable for shipbuilding or railroad work, and regulations prevent the dealers from acquiring a stock for transient business. The general market is quiet and dealers report no change in prices.

Metals Are Steady

Activity in metals continues in fair volume but without any special features. The demand is steady, but the market is virtually under War Board control so that the situation is one not likely to be influenced by domestic conditions. Little metal is available at the present time for other than essential requirements related to war needs. The demand for copper is quite active, but the control price maintains the market at a steady level. The supply of tin is more plentiful and the market is easier. The bulk of this metal, however, is applied either directly or indirectly for war purposes. Local dealers are quoting from \$1.05 to \$1.10 per lb. Spelter and lead are both firm and dealers are asking 11 cents and 10½ cents respectively. The demand for antimony is a little more active and the available supply is only sufficient to meet the immediate needs. Dealers here have advanced one cent and are quoting 16½ cents per lb. Aluminum is steady and firm at 50 cents per lb.

Machine Tools Active

The demand for shell making equipment is not heavy, but enquiries would indicate that business is still quite active. The probability that many shell contracts will be renewed has added to the likelihood of further trading in machine tools. Enquiry for general equipment is also active, but the buying is less pronounced.

Scrap Trade Quiet

Little of interest is taking place in the old material situation and dealers report a very quiet market. The trade is so controlled at present that dealers are reluctant to deal in small quantities as the cost of handling scrap under existing conditions is excessive in relation to the prevailing prices. It is sometimes necessary for dealers to turn down a sale owing to the prohibitive cost of haulage. The local market has remained practically unchanged in most lines of scrap, but car wheels and axles have advanced. Iron car wheels are now quoted at \$38, against \$26 of a few weeks ago. Wrought iron R. R. axles are also stronger, the prices asked ranging as high as \$40 per ton. Increased supply of machine shop turnings has created a weaker market, the current price of \$8 being a drop of \$1 per ton. Cast borings at \$10 show a decline of \$2 per ton. Stove plate has advanced from \$26 to \$30 per ton.

The market in heavy lead is not so active and dealers have reduced quotations to 7 cents per pound.

THE LOWLY SCRAP HEAP IS OCCUPYING A BIG PLACE NOW

THE scrap metal situation in United States is not much like the Canadian conditions. In American points the demand is keen and supplies are short. In the Dominion the very reverse seems the case. The supplies are rather plentiful but trade is slow.

Reports from some of the larger points in U. S. follow:

Chicago.—Trade is diminishing here because there is no relief from the shortage. There are no reserves to speak of being laid up against the Winter months when deliveries will be slow and transportation worse.

New York.—The Jewish holidays that have been taking place in connection with their New Year have interfered with the scrap metal business to some extent. In fact it does not take much letting up in this direction to make a decided difference now. Some dealers have standing orders for all the material they have in their yards.

Pittsburgh.—Yards here are getting pretty well thinned out, and the work of filling them up again is making very poor progress. Dealers are going after and securing grades of scrap that they would not look at in ordinary times. More shell steel is to be made here and there may be relief in the way of increased amounts of shell turnings, etc.

Cleveland.—Dealers here state that the railroad situation is absolutely the worst in weeks. There is a big demand for heavy melting steel. Many delays are encountered in the sorting of material.

Cincinnati.—The profits on the scrap metal business are not large now, according to dealers, who claim that sellers of scrap are insisting on getting the full maximum price, leaving the dealer only the commission allowed by the Government. Dealers say that they cannot do business on this scale and avoid failure.

MANGANESE FOUND IN BRITISH COLUMBIA

Claims Made That Returned Soldier Knew Where Large Deposits of This Were

Discovery of manganese on Vancouver Island is being hailed on the Pacific coast as one of the most notable finds of minerals that Canada has known for some time. Mineralogists who have made inspections of the area in which the discovery has been made have stated that the property near Cowichan Lake is one of the finest prospects yet uncovered.

An Engineer Runs Into All Sorts of Jobs

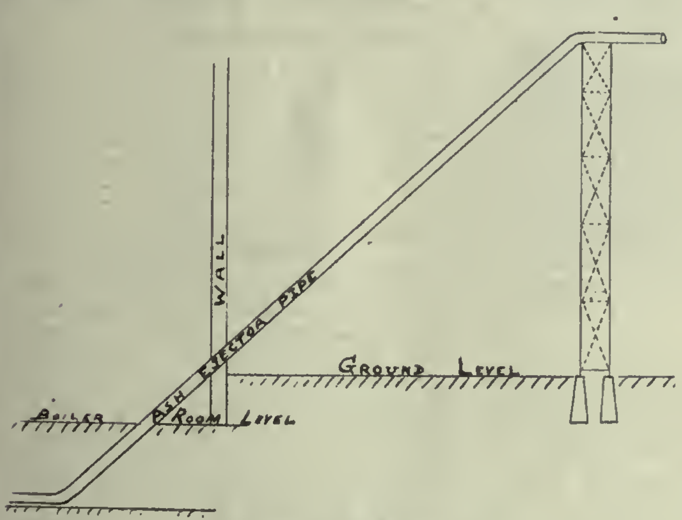
How a Structural Steel Tower Was Lowered Four Feet With Very Little Equipment or Staff to do it With—Essential Thing Had Been Overlooked in the Plans For the Work

By T. H. FENNER, Associate Editor Canadian Machinery

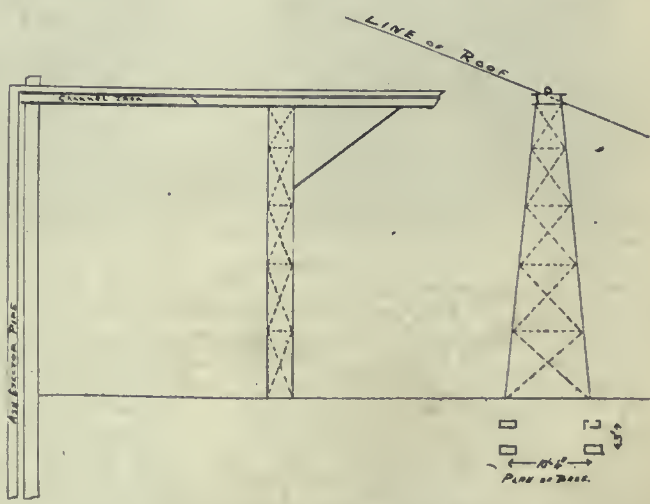
AS an instance of the unexpected propositions a mechanical superintendent is liable to run into, the following will be of interest.

A large industrial corporation was making an installation of coal and ash handing machinery for their power plant, and in connection with the ash ejector it was necessary to have erected a structural steel tower to carry the pipe from the boiler room by means of two channel irons resting on the tower and on the boiler room wall. The location of the tower and beams had been determined by the firm supplying the equipment from blue prints of the power house supplied them by the customer. The arrangement as originally submitted differed materially from that finally adopted, and in making the change one material factor was overlooked by all the parties concerned. The original and final arrangements are shown in the sketches accompanying. The tower was not to be supplied by the concern selling the ash handling equipment, they merely furnishing the design and location to suit their equipment. The factory engineering staff were looking after the erection of all the machinery. Feeling, however, that building structural was perhaps a little out of their line, the job of building and erecting the tower was given out to a constructional steel company. The approximate dimensions of the tower were thirty-five feet high, three feet in width at the bottom in one direction by ten feet wide in another, as shown in the sketch. The main posts were made of 3½ x 3½ x 5-16 angle iron, and the cross bracing of 1½ x 1½ x 3-16 angle iron. The corner posts were bolted at the bottom to four concrete piers, 5 ft. long, by 1 foot square at the top, by 18 inches square at the bottom.

The foundations were placed by the factory staff in accordance with the drawings made by the firm supplying the equipment, and the steel construction people were notified that they could erect the tower and channel irons as soon as they were ready. In due course the gang arrived with the sections of the tower loaded on a large motor truck and men enough to make short work of the erecting. They started in right away to unload the truck and went at the job of coupling the sections of the legs together. The legs were made in two lengths of seventeen feet six inches, making when coupled together the required thirty-five feet. Two sides were laid on the ground with the base close to the foundation. Two or three angle irons were bolted across the posts to hold them together, and they were ready to raise up. Here an object lesson was obtained on the versatility of a well behaved motor truck. The two posts, comprising one side of the tower were raised by the combined efforts of the erecting crew till high enough to enable the truck to back in under them. They were then allowed to rest on the car and the car continued to back, thus raising the posts, when at an angle about forty-five degrees they were blocked up and the guy ropes fastened to the top end. A trestle was then put on the motor truck, catching the posts about half way



ORIGINAL ARRANGEMENT



ARRANGEMENT AS ADOPTED

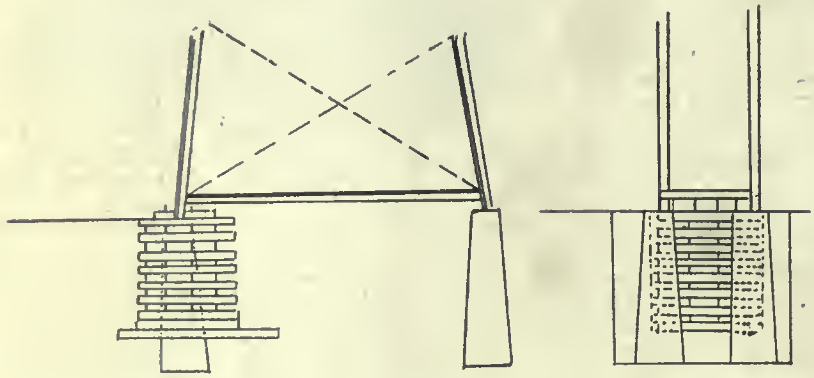
up, and the car again backed up, this time raising the posts almost to the vertical. A good pull on the guy ropes and the two posts stood up in their place, and one side of the tower was erected. Everything was going fine, and in a very short time the other two posts were raised and the men started putting the bracing on.

The Trouble Started

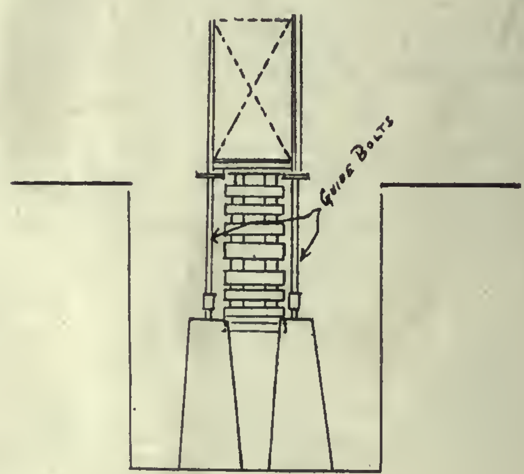
The next operation was to put up the channel iron beams, and here was where the unexpected happened. It was discovered that one of the beams, instead of passing through the wall below the roof, would come out on top of the roof, while the other one would be under the roof, but too close up to it. How had this occurred? A hurried look over the drawing in the light of this new condition disclosed the fact that in altering the plans the angle of the roof had not been taken into account with the result already mentioned. The next question was, what was to be done? The steel men, anxious to get their job done and get away were for cutting the roof. As this roof had been re-slated only the year before at a cost of several thousand dollars, cutting holes in it was not desirable, especially a hole large enough to allow for the beams and the pipe on top of them. The contractors then washed their hands of the job and left, without any further comment. The chief engineer of the plant then decided he would lower the tower bodily just as it stood, lowering the foundations first and then bringing the tower down to them. It would have been easier to take down the tower first if he had the men available, but the staff at his disposal was woefully small and not particularly suited to a job of that kind, and the time necessary to dismantle and re-erect after would have entailed too much expense. The chief thing to guard against in performing the operation of lowering the tower lay in its capsizing on the narrow base, it being fairly stable on the 10 feet direction.

How it Was Done

The method adopted was as follows: Guy ropes were attached to the tower near the top, leading at right angles to the long base to counteract the tipping action on the short side. The ground was dug away from between the foundations to a depth sufficient to allow for the complete amount of lowering required. A crib work of 3 in. planks was then built in this space till it supported the tower on its lower cross-angle irons. The nuts on the holding down bolts of the two side piers were then taken off. The bolts projected through the base of the tower about 3 ins., they having been left long to allow for adjusting, after which they were to be cut off flush. A strong wooden horse, or trestle, which was in use around the mill for general millwright work was brought over to the job and placed close up to the posts of the tower parallel to its narrow axis. Two pair of triplex chain blocks were hung on the trestle and made fast to the base angle close to the post on each side. By heaving up on these blocks the base of the tower was raised to clear the foundation bolts on the two piers, the two on the opposite side being left fast to act as a counterweight. As soon as it was raised high enough to clear the bolts it was blocked up in this position and the chain blocks let go. One was made fast to the chain block and raised out of the pit, making room for a man to get down and dig. The ground was dug out where the pier had been to a depth of four feet and the companion pier was moved from its position and dropped in the hole. This saved lifting it out, and still left room enough for a man to work, making the excavation for the other pier. When this was done the earth was levelled off between the two piers, leaving the floor level at the new depth, and the first pier was dropped down into the place vacated by the second. Two long studs were made, six inches longer than the depth of the new excavation, and these were fitted with a screwed sleeve at one end, which sleeve also screwed onto the top of the holding-down bolt in the pier. The bolt was passed through the hole in the base of the tower and an efficient connection made between the tower and the pier, although they were four feet apart. This served to make one side secure, while the piers were dropped from the other side and the excavations made. (These precautions were necessary as the tower swayed considerably and there was at times a strong wind). When all the piers were in place and the long bolts in position, the tower resting on the blocking, all was ready for the lowering proper. A second trestle was brought up and placed on the other side and two more pair of blocks used. This made it possible to tip the tower on any of the four corners. The first move was to take the weight of one side of the tower on the blocks and remove one course of three inch blocking, then lowering till the tower rested on the next course. Having been level at first the tower was now three inches lower at this side than the other. The strain was kept on the long bolts on this side, and the chain blocks on the opposite side tightened up till the wooden blocking was free. This side was now lowered six inches, making it three inches lower than the side first lowered. This process was repeated alternately on each side till the full four feet had been attained and the tower rested on its foundations again four feet below its original level.



BLOCKING BEFORE MOVING PIERS.



READY FOR LOWERING

METAL RECLAMATION ON THE WESTERN FRONT

In a New York paper recently to hand mention is made of the vast amount of wreckage reclaimed from the battlefields on the Allied front. It states that an average of 7,800 tons of used shell cartridges and about 4,500 tons of various metals are sent monthly to the sorting centres. The work of clearing up is systematically organized, special formations of men being regularly detailed for that purpose. Nothing is overlooked. Everything that can be used is preserved and shipped to a supply depot.

Great minds have purposes; others have wishes.—Washington Irving.

It's not life that matters; it is the courage that you bring to it.—Hugh Walpole.

What Canada is Doing for the Returned Soldier

The Work Being Done in Re-education is Little Appreciated by Those Who do Not Come Into Intimate Contact With it—A Series of Articles, of Which This is the First, Will be Given, Going Into the Detail of the Soldiers' Industrial Re-education

By W. F. SUTHERLAND, Associate Editor Canadian Machinery

LITTLE need be said as to the magnitude of the debt which is owing to those who have been maimed in the service of their country and the whole-hearted spirit with which the government and industries of Canada are co-operating in the reestablishment of the soldier in peaceful pursuits can only be commended in the highest terms.

Every soldier who returns from the front disabled and unable to follow his former vocation is given the opportunity to learn new trades, trades which in the majority of cases are much more remunerative and pleasant that those at which he formerly worked. The majority of us realize at times, perhaps with a bitter sense of regret, that opportunities for education and training in professions closed to us through lack of knowledge do not come with advancing years and the ever-present struggle to make a living wage. The opportunity, then, afforded the disabled soldier to advance his education and to fit himself for better things is in many cases the fulfilment of a lifelong ambition.

Re-education is necessarily closely allied to the restoring of the soldier to complete health and the proper technical training and particular trade learned depend in a large measure upon the disabillties received at the front. While these problems are mutually dependent, vocational training is divided into two distinct branches, occupational therapy and industrial re-education both handled in Canada by the Department of the Soldiers Civil Re-establishment.

Occupational therapy is that part of the training received while the soldier is still under medical care and in some cases has no connection with the training given after the patient is discharged from the hospitals and other institutions as cured. Its main object is to relieve the many weeks sometimes required for convalescence of some of their monotony and tediousness and at the same time to assist in the curing of disabilities by means of movement or exercise necessary to the restoring of injured members to normal use. For instance, to exercise the limb in a case of foot or leg injury and at the same time to divert the patient's mind fret-saw work may be given, or for arm injuries light work of some other kind. But even in occupational therapy the idea now is to give that sort of work which will be preliminary to and dovetail in with real vocational education, which is to begin as soon as the patient is ready to receive further education. If for instance the patient was formerly a sheet metal worker and through injury is debarred from the use of physical strength he is started perhaps as a designer or architectural draftsman in cornice, sheet metal or other architectural design. His practical knowledge is thus built upon and focused in a specialty suited to his capabilities.

"Instead of making futile little baskets or weaving mats that would have no sale except as a camouflage for downright charity, he is furnished with a set of instruments, a bed drawing board and some text books, and given able instruction. The weeks in bed or in wheel chair are utilized practically. When he is able to go into the shops he is well along as a technician and ready for further intensive training."

Scope of Vocational Training

It is well to remember, as before stated, that there are two distinct classifications in this work and the striking difference in the two branches is well noted in the fact that the United States placed them in two totally different departments of the Government. Occupational therapy will be carried out by the Surgeon-General's Department, and industrial re-education by the Federal Board for Vocational Education.

While the above is the case in the United States, Canada has placed the whole problem of industrial re-education and the pension system under the jurisdiction of the department of the Soldiers' Civil Re-establishment, the two branches of this being the Pensions branch and the Invalided Soldiers' Commission, the latter taking over the work formerly done by the Military Hospitals Commission. Occupational therapy is conducted by the department in the hospitals under army doctor direction. When the soldier is discharged as cured the department takes charge entirely and both he and his family, while he is in training, are kept medically and mentally fit. The honorable

VARIOUS WELDING OPERATIONS BY THE OXY-ACETYLENE TORCH IN L'AIR LIQUIDE SOCIETY PORTION OF THE EXHIBIT OF THE DEPARTMENT OF THE SOLDIERS' CIVIL RE-ESTABLISHMENT.

Geo. Foster in a recent statement said that "The Department fathers and mothers the man until he is able to earn his own living."

The soldier, to all intents and purposes a civilian, has his pension suspended while in training but is recompensed by the allotment to him of vocational pay and allowances graduated as follows:

	Per Month
Single men	$50.00
Man and wife—no children	73.00
Man and wife—one child	80.00
Man and wife—two children	85.00
Man and wife—three children	88.00
Man and wife—four children	91.00
Man and wife—five children	93.00
Man and wife—six children	94.00

"Industrial re-education was established as a means of saving disabled men from being a dead loss both to themselves and to the country. It is intended for disabled men who are so handicapped by their disabilities that they cannot return to their former occupations. There is no desire to take all the square pegs in the army and to fit them into round holes for the sheer fun of changing things all around. Round pegs which have been squared by the scars of war are unfortunate in having to be readjusted to holes of another shape, but the Department of Soldiers' Civil Re-establishment has built up an organization which is efficiently doing that work. Be it said to the credit of young Canada that of nearly five thousand men who have been found in need of industrial re-education to enable them to maintain themselves and their families as independent self-supporting citizens, only about three hundred have refused the opportunity offered them. In England and France one of the biggest problems the rehabilitation agencies have to face is that of inducing men to accept the training offered them."

Opportunities Available

There is no set number of courses in which industrial re-education is given. Each individual man is trained for the occupation in which he is best qualified to become proficient. If courses were established it is probable that only a limited number would be available, but by the department's policy of placing men in industries after preliminary training in the use of tools or in English or mathematics the whole head field of industry is open for their development and over 200 different occupations have been rendered available.

As a contrast to the work being done it is interesting to read of some of the schemes being put forward by well-intentioned but misinformed people and a recent statement by the Federal Board for vocational training for the United States is given:

"Clearing Up A Point"

"There appears to exist in the minds of many people a total misconception of what vocational re-education is, as applied to disabled soldiers and sailors. The Federal Board for Vocational Education, which is charged with the duty of re-educating the injured men, is constantly receiving communications from people who have this, that, or the other supposed art or craft which is offered as being just the thing to teach the poor dear wounded soldiers. These suggestions run all the way from making art-craft out of sealing wax, making paper flowers, and gilding pine cones, to constructing alleged ornaments out of putty.

"The Federal Board does not propose to teach any such rubbish. The education to be given will in the main be in highly specialized occupations which are good paying, recognized, and manly callings which have a definite, useful place in the business world, and a steady demand for such work or the products thereof.

"The difficulty appears to be that many of these well-intentioned advocates of gilded peanut hulls and gimcrack nicknack making are mentally confused, and do not know either what occupational therapeutics and vocational education are, or the part they play. The former is given to divert the patient's mind, to exercise some particular set of muscles or a limb, or perhaps merely to relieve the tedium of convalescence. Occasionally these activities have little or any practical value beyond the immediate purpose they serve, nor are they intended to have any other value."

After the soldier leaves the hospital and is able to undertake training in any desired occupation he is not left to his own devices but under the care of the department is given his vocational pay and receives his instruction free. This instruction is given in the plants of various manufacturers who are devoting space, tools and instructors to the work and who in many cases are able to place the soldier at the expiration of his course of training in their own shops.

If the occupation is such that it can only be learned by the equivalent of a partial university training, this is given by competent instructors at the various universities and technical schools of the country. This instruction may be and often is supplemented by practical work in the shop.

The length of the various courses is approximately six months, although the time taken is fixed only by the soldiers' capabilities and difficulties of the subject undertaken. In every case the work is recognized as distinct from factory production and is directed with a view to education not manufacturing, any benefit to the manufacturer arising from the work being done occuring afterwards, when the soldier if he wishes is engaged on the regular staff.

Re-Educational Work at the Fair

The recent exhibit of the work being done in the re-education of the soldier at the Toronto Exhibition was undertaken that the general public might know something of the results accomplished.

SIR JAMES LOUGHEED, MINISTER OF RECONSTRUCTION, VISITING THE RUSSELL MOTOR CAR SECTION OF THE EXHIBIT OF THE DEPARTMENT OF THE SOLDIERS' CIVIL RE-ESTABLISHMENT.

Occupational therapy was illustrated in the many pieces of fancy work, art weaving, wood carving, hammered brass and bronze articles shown and in the group of men working on the fashioning of similar objects.

L'air Liquide Society is one of the firms which is training returned soldiers and various welding operations were shown in their portion of the exhibit.

The Burroughes Adding Machine Co. had a large display, about a dozen men being at work on various parts of the machines. In this work the men are given a four months' course, three months in the school and a month at actual work. The course includes instruction in operating, construction, and repairing, embracing all the features of the various machines manufactured. The Burroughes Co., at its plant at Windsor, will employ none but returned soldiers, and a movement is on foot to have this rule apply also to the Detroit factory.

In the Russell Motor Car Co.'s corner eight returned men were at work, designing and making tools and parts. An engine lathe, a crank shaping machine, and a universal milling machine were shown in operation. The Russell Co. has a special school for ex-soldiers at 265 Adelaide street west. At present about 20 men are taking the course, which lasts about six months. In this time the firm aims to turn out mechanics as good as those who have had several years' experience in the plant. The eight men who have already graduated are doing very good work.

Several Working on Ores

In the space occupied by the assaying department of Toronto University half a dozen men were busy on scorification work. Galena ore was being put through a muffle furnace, heated to 1,000 degrees Centigrade, to determine its value in silver per ton.

Roden Bros., silversmiths, demonstrated work done at their plant by returned men. This included silver polishing and cut glass work. They give the men a six months' course in their various departments.

The Lanston Monotype Machine Co.'s corner had several men engaged on monotype machines. This company gives a course in keyboard work or casting to returned men, the former being open to only those who were printers before enlisting. The course lasts for about six weeks, and so far more than 20 men have been turned out and have found good positions.

The Multicolor Sales Co. demonstrated work with office presses, which print anything from a business card to a display card nine inches by fourteen. Their course lasts two months.

The Consolidated Optical Co.'s training includes all features of the manufacturing end of the optical business. In their corner of the big display several returned men were shown at work grinding, finishing, making frames and bridges, etc.

How Germany Forged U.S. Passports in the War

Attempting to Give Military Aid to the German Empire—Large Sums Were Spent, But the Fraud Was Soon Detected—How the Scheme Was Shadowed by Secret Service Men

By EARL E. SPERRY and WILLIS M. WEST, for U. S. Commission on Public Information.

THE third chief purpose of Germany's diplomatic officials in the United States was to send troops and munitions to the Central Empires. When the war began in July, 1914, large numbers of German reservists were living in America, and in order to avoid capture on their way home many of them sought under false names to obtain passports as American citizens. They thus violated the law that American passports shall be issued only to citizens of the United States, and also discredited genuine passports, thereby causing delay and distress to American citizens abroad. Their action also was a violation of America's neutrality and endangered its national honor and safety.

In order to have at hand an adequate supply of counterfeit passports, the German Embassy maintained an office in New York City, directed by Captain von Papen, where they were forged by wholesale. German consuls in distant cities, as Chicago and St. Paul, were informed concerning this office and sent there for passports the reservists from their several localities.

These operations were known almost from the first to the United States Secret Service. Hans A. von Wedell, who managed the office, took alarm and fled in November, 1914, supplied with money by von Papen. In the following letter, found on one of his associates, who was arrested before he had an opportunity to post it, von Wedell exonerates himself from the charge of deserting his post and shows the complicity of the German Ambassador in the business of forging passports:

His Excellency, The Imperial German Ambassador,
Count von Bernstorff, Washington, D.C.:
. . . My work was done. At my departure I left the service well organized, and worked out in minute detail, in the hands of my successor, Mr. Karl Ruroede, picked out by myself. . . . Also, Ruroede will testify to you that without my preliminary labors, it would be impossible for him, as well as for Mr. von Papen, to forward officers in any way whatever. (He then explains in detail his reason for hiding.) . . . Ten days before my departure I learned from a telegram sent me by Mr. von Papen . . . that Dr. Starck had fallen into the hands of the British. That gentleman's forged papers were liable to come back and could . . . be traced to me. Mr. von Papen had repeatedly and urgently ordered me to hide myself. Mr. Igel told me that I was taking the matter altogether too lightly, and that I ought, for God's sake, to disappear. . . .
With expressions of the most exquisite consideration, I am your Excellency's
Very respectfully,
(Sgd.) HANS ADAM VON WEDELL.

The connection of von Wedell with the German Embassy in the United States is further shown by the following entry in the checkbook of Captain von Papen:

1914	
Nov. 21—A. von Wedell	$300
" 24—(For Wedell)	240
" 27—(For Wedell)	150
" 30—Wedell	500
Dec. 5—Wedell	500
" 8—Wedell (journey money)	300
" 22—von Wedell	800

Karl Ruroede at once took up von Wedell's work in a different office. He was under the constant surveillance of Secret Service men, one of whom entered his employ and made frequent reports, from one of which an extract follows, concerning conversations with Ruroede:

"You say von Wedell spent $3,500 of his own money?" I asked. "No, no, he got it from the fund." "Well, who puts up this fund?" said Ruroede. "You see, there is a German captain here who is attached to the German Embassy at Washington. He has a list of German reservists in this country, and is in touch with the German consulates throughout the country, and in Peru, Chile, Mexico, etc. He communicates with them, and the consuls send reservists on to New York. On their arrival the Captain tells them . . . 'Go down and see Ruroede.' Sometimes he gives them his card. . . . He draws on this fund for $20 or $300 or $1,000, whatever he needs, and the checks read, 'On account of Reserves.' You see they have to have food and clothing, so there's nothing to show that the money is used for passports. . . . I meet the captain once a week . . . and he gives me whatever money I need. . . . You know there must be no letters, no accounts, nothing in writing."

"If things work out all right now," he said, "we shall be good for three or four hundred passports, and no telling how many more."

When the Norwegian steamer *Bergensfjord* sailed on January 2, 1915, she had on board four German reservists, all of whom were provided with American passports by Ruroede, who had unknowingly obtained them from a United States Secret Service man. As the big liner dropped down the bay she was followed by a United States Revenue Cutter with Federal officers. At quarantine they boarded the steamer, arrested the reservists, and brought them back to New York. Ruroede also was arrested, pleaded guilty at his trial, and was sentenced to three years in the Federal penitentiary at Atlantic. The reservists, guilty of forgery, were punished by fines of $200 each. Charles A. Oberwager was Ruroede's counsel, and under date of January 6, 1915, Captain von Papen's checkbook contained the following entry: "(For Oberwager) $2,000."

German agents in Chicago were making a similar use of American passports. A German reservist reported the following conversation with G. H. Jacobsen, who was implicated in many criminal undertakings in aid of Germany:

Jacobsen told me that an officer who had someone else's citizenship (passport) had shipped for Germany, and when he reached Holland the papers would be delivered to some German agent and sent back, and I could then use them to leave the United States.

Jacobsen obtained citizenship papers for the use of German officers from members of the German Club; and when the description did not fit the person who was to use it, a German printer in Chicago made the description fit by changing it.

There are many cases, from which the following are a selection, in which American passports were fraudulently procured and used for unneutral purposes. Captain Boy-Ed, Richard P. Stegler, a German citizen, Richard Madden, and Vincent Cook secured through conspiracy an American passport to be used by Stegler while serving as a spy in Europe. Boy-Ed financed and directed Stegler's operations, but was protected from prosecution by his diplomatic immunity. Madden and Cook were sentenced to ten months and Stegler to sixty days in jail.

Ilbert Sanders and Charles Wunnenberg, German agents in this country, have pleaded guilty in New York to the charge of sending German spies to England equipped with American passports which was used by Stephen Geisner, an attaché of the Austrian-Hungarian Consulate at New York City, to return to Austria.

The diplomatic officials of Germany hired American citizens protected by genuine passports to use them for dishonorable and unneutral purposes, such as to carry German dispatches and to act as spies in England. E. G. Woodford, for example, who was sent to Europe by German officials here was paid $550 for his services on orders from Berlin. The payments to him are recorded in the cashbook of Wolf von Igel.

Fraudulent Manifests

German agents in the United States also endeavored to give military aid to their country by sending coal and other supplies to German warships which were raiding commerce in both the Atlantic and Pacific oceans. Such action was a violation of American neutrality, and in order to evade the law the conspirators took false oaths before Federal officials concerning the ownership of vessels, the nature of their cargoes, and their destination. These acts, even more than the use of forged passports, were likely to cause friction between the United States and countries with which it was at peace.

The Hamburg-American Line, through its high officials in New York, repeatedly defrauded the United States by procuring false manifests. Among those involved were Dr. Buenz, managing director, George Koetter, superintending engineer, Adolph Hachmeister, purchasing agent, and Joseph Pappinghaus, who together worked up an elaborate machinery to deceive the Government. They confessed at their trial that they had sent out twelve ships, which were proved by the Government to have fraudulent papers and all of which were captured and interned before reaching their destination. Nine of these vessels were chartered, and the Hamburg-American Line paid to the owners for their losses about $1,400,000. The following copy of Captain Boy-Ed's account at a New York bank indicates that he had large sums at his disposal for conducting Germany's naval operations from the United States, and that he reimbursed the Hamburg-American Line for this and other expenditures:

1914	
July 24—Received from National Bank of Commerce	$ 250,000.00
" 26—Received from A. Vogel	70,000.00
Aug. 1—Received from National City Bank	100,000.00
" 1—Received from Speyer & Co.	100,000.00
" 2—Received from National City Bank	200,000.00
" 3—Received from Speyer & Co.	500,000.00
" 5—Received from Bayer Co., Inc.	300,000.00
" 16—Received from Kuhn, Loeb & Co.	35,000.00
" 24—Interest	1,941.11
Oct. 26—Received from National City Bank	300,000.00
" 27—Received from Kuhn, Loeb & Co.	150,000.00
" 29—Received from Kuhn, Loeb & Co.	1,200 000.00
Dec. 1—Interest	5,253.00
	$3,262,197.11
Oct. 24—Paid to Hamburg-American Line	$1,200,000.00
Dec. 2—Paid to Hamburg-American Line	1,961,365.36

Gustav B. Kulenkampf of New York, who was employed by the Hamburg-American Line to draw up the false manifests, stated at the trial that he received $750,000, which was subject to the order of Captain Boy-Ed, naval attaché of the German Embassy, and was largely spent on the Pacific Coast. His evidence proved that, like the forgery of passports, fraud and perjury were committed under the direction of German officials protected by the diplomatic privileges which all civilzed nations consider sacred. Buenz, Koetter, and Hachmeister were found guilty of conspiracy to defraud the United States, and were sentenced in December, 1915, to eighteen months in the Federal penitentiary at Atlanta. Pappinghaus was sentenced to a year and a day.

Similar means were employed by German agents on the western coast under the direction of Captain Boy-Ed to send provisions and coal to German raiders in the Pacific. The steamers *Sacramento and Mazatlan* were there engaged in this illicit traffic. When the *Sacramento* once cleared with a large cargo for Valparaiso, Chile, but reached there empty, the captain explained that on the way down she had been commandeered by the German fleet and her cargo removed. Besides the Hamburg-American officials already mentioned, more than 15 individuals and firms have been convicted in the United States courts of fraud or perjury in their efforts to assist Germany by illegal means.

Perjury was also employed in a notable instance to justify Germany's conduct. When the passenger liner *Lusitania* was sunk by a submarine on May 7, 1915, with its great load of non-combatants, the German Government and its ambassador in America asserted tht she was in law and fact ship of war because laden with ammunition and armed with four cannon. In order to prove this statement, Ambassador von Bernstorff sent to the Department ot State four affidavits swearing that the *Lusitania* was armed. Three of these were worthless as testimony, and the fourth had been procured by Paul Koenig, of the Hamburg-American Line, from Gustav Stahl, a German reservist. Federal officials knew that the *Lusitania* was not armed and that Stahl must have sworn falsely. He was accordingly tried for perjury, confessed his guilt, and was sentenced to eighteen months in the Federal penitentiary at Atlanta.

Violations of Parole

When the British fleet was clearing the seas of enemy warships, two German cruisers, *Printz Eitel Friedrich* and *Kronprinz Wilhelm* sought refuge in the harbor of Norfolk, where they were interned. The German officers pledged their word of honor to our Government, which had opened the harbor for their protection, that they would not escape from the jurisdiction of the United States, and accordingly were allowed every liberty.

Several officers of the *Kronprinz Wilhelm* purchased a yacht after some weeks had passed, on the pretense that it was for pleasure cruises. They secretly stocked it with supplies and one night sailed away. They were given the necessary funds for their escape by the German Consul at Richmond, and Captain Boy-Ed filed a message at Sayville, asking the German authorities in Berlin for instructions for these officers. Paroled German officers at San Francisco and Guam also violated their oaths to remain within the jurisdiction of the United States.

The Military Information Bureau

The collection of data concerning the production of war materials in the United States and its transmission to Germany were among the many duties of Ambassador von Bernstorff and his attachés. A Military Information Bureau under the direction of Captain von Papen was maintained for this purpose at 60 Wall Street, New York City. The following memorandum found among the papers seized there by the Federal authorities gives some insight into the methods of von Papen:

(Strictly Confidential)

New York, December 16, 1915.

Memorandum.—This refers to my call at your residence on Monday last, during which you requested me that I should make every effort to get particulars regarding a certain rifle, said to be manufactured by the Westinghouse Company.

In connection herewith I have now made certain connections which may result in being able to accomplish the above. I have been given to understand that I may even procure a sample, if it can be had.

As this matter may necessitate an expenditure of from $100 to $200, would ask you to consider whether it would be advisable to lay out such an amount for information of this kind, including a sample rifle; should the latter not be absolutely necessary, probably I can secure a description of the rifle at a very limited expense.

Would appreciate if you would let me know what is desired.

Yours faithfully,

XXX.

"XXX" was the symbol used in confidential correspondence with the German Embassy and its attachés to designate Paul Koenig, director of spies, who, among many other duties, collected information about the manufacture and transportation of munitions. His most valuable source of knowledge was a clerk in the National City Bank of New York, Frederick Schleindl, through whose hands passed not only telegrams from the Allied states transmitting money for the purchase of war materials, but also orders for them and letters of advice from the manufacturers, which frequently named the railway by which the munitions were transported and the vessels to which they were consigned. For men who were endeavoring to burn or blow up munition ships, such information was invaluable.

Schleindl went at least once a week to Koenig's office in the Hamburg-American building with letters from various military attachés, agents, and brokers of the Allies. These and other stolen documents were copied and then restored to the files of the bank on the following morning. Schleindl received from Koenig $25 a week for this service.

That Hans Tauscher also assisted von Papen in the work of gathering military information, is shown by a bill of $157.65 sent to him by B. Glaser, of New York City, for "investigating and obtaining cartridges from December 4 to December 10." This investigation was made at Bridgeport, Connecticut, and to obtain the desired information and the samples of cartridges, money was paid to girls and forewomen employed in the factories. Captain von Papen's checkbook shows the following record: "Dec. 18, H. Tauscher (for Glaser, Bridgeport), $157.65."

One Theodore Otto also made frequent statistical reports to the German embassy on the manufacture of munitions and arms at various American factories.

A notice in a German technical paper for May 8th states that the important Bavarian establishments for the production of nitric acid from the air are to undergo considerable extension, in which some 200,000 horse-power of water-power will be used. A strong syndicate of bankers and others has been formed to carry out the scheme, which will involve a capital of 150 million marks.

* * *

THE ELECTRIC furnace has made possible what may be regarded as almost a revolution in the steel industry. It is the conversion of scrap steel or iron back into pig iron. What may be called "synthetic pig iron" is now a commercial product; in other words, the original constituents of pig iron are being made to reunite in the condition originally assumed. This unusual achievement is another evidence of the adaptability of electrical energy to the production of results impossible by any other means. The new process is being applied commercially in a large electric steel plant in the eastern part of the United States, high-grade or- low-phosphorus pig iron being made directly from ordinary scrap steel. Not only is pig iron being produced in large quantities, but "wash" metal and iron and steel castings are made in the same furnaces. The pig iron sells in the open market as a competitor with regular low-phosphorus blast-furnace iron, the wash-metal goes to crucible steel makers, and the iron castings are sold to local users, or else are used by the company in its rolling mill. The idea is not new, but this is the first record of its commercial exploitation in the United States.

Safety Code for the Operation of Electric Cranes

Association of Iron and Steel Electrical Engineers Formulates Complete Set of Rules For Operators—Adoption of Rules Will Lead to Fewer Accidents and Less Loss

A COMPLETE set of rules for the safe operation of electric cranes which may be the means of avoiding heavy losses through damage claims and which were prepared after an exhaustive study of the situation with respect to the rights of employers and employees and the law was presented to the Association of Iron and Steel Electrical Engineers by its safety committee at the association's twelfth annual convention in Baltimore, Sept. 11-14.

The committee in its report emphasized the necessity of the employer placing in the hands of his employees printed rules that should be complied with for prevention of accidents, stating that only by so doing may the employer remove the possibility of an injured workman obtaining excessive damages on the grounds that he had not been properly warned. Verbal instruction may be denied and a doubt created which would be favorable to the contestant. The law implies and in some cases demands that hazards of every situation employees are brought in contact with shall be made known to them before they begin work; also that they be instructed how to do their work so that no injury befall themselves or fellow workmen.

The committee declares that the rules should be understood by employers as well as employees and that they should be carried out even at the cost of delays. The rules provide for their own enforcement, each rule being followed by explanatory paragraphs stating the authority and duty of the employee. The rules follow:

1. While the operators of cranes usually are subject to orders of operating foremen, in the departments where they are employed, they should not start a motor even when ordered to do so, if so doing is likely to cause an accident.

(a) A signal to stop the travel of a crane or the movement of any of its parts, by whoever given, should be obeyed.

(b) A motor should not be started, to make a lift, if the operator knows that an improper hitch has been made with chains or slings, or if hooks permanently attached to the crane fixtures are not properly adjusted.

(c) In any case of doubt as to making a lift with safety the crane operator should call the attention of the foreman in charge to the condition that created the doubt.

2. The crane operator should be held responsible for the safe condition of his crane insomuch as he should know by observation from his cab and from inspections of the entire crane.

(a) He should see that all bearings are properly oiled; that all cables are traveling properly on their drums; that brakes, limited devices, controllers, switches, hooks, yokes, blocks and other attachments are in good and proper condition.

3. Operation of cranes while doing construction or repair work should be governed by a code of signals prescribed by the management. They should be given by some one person known by the operator to have authority. On occasions when it obviously is necessary to deviate from this rule the operator should act with exceeding caution.

(a) Cranes engaged in their regular routine work should follow such practices as is the custom in the mills they are operated in and as has been agreed on by the operating management.

(b) Changing rolls, removing and replacing parts of machinery, working two cranes to lift one load, and all unusual operations are classified with repair work and operators should be governed by signals when cranes are so employed.

4. When more than one crane is operating on a runway, an audible signal should be sounded, to avoid collisions when moving. Signals should be sounded when cranes are moving while carrying suspended loads in the vicinity of where men are working.

5. Cranes carrying material should be so manipulated as to avoid carrying suspended loads, or magnets with or without loads, over men working below. In cases where men working below cannot or do not from any cause whatever move away the crane should stop if the line of travel of the load or magnet is over the workmen.

6. Operators on leaving their crane cabs to inspect, oil or repair parts, or to get off the crane, should open the main switch and lock it open with a safety seal lock.

(a) Switches controlling the current to magnets should be kept constantly open and locked open while the magnets are detached, or while they are not in use.

(b) On notification from workmen that they want to disconnect the magnet, the operator should open the main switch and lock it open, before the wires are disconnected.

7. When handling ladles filled with molten metal, the brakes for controlling ladle hoists should be tried to see if they are in good working order before the ladle is moved from over its support. To make this trial the ladle should be lifted a slight distance, then apply the brake to see if it will hold the load.

(a) Ladle cranes with but single motors and outfits for the ladle hoists should not be used to handle a ladle containing metal when the brakes will not hold.

8. Operators should not leave the crane cab for any purpose whatever while a heat of metal is suspended from the crane. In case any adjustment of parts of the crane is required help should be called on to make it.

9. Operators should be responsible for preventing men from riding on their cranes who are not required to do so for some purpose. They also should be responsible for preventing men from riding on any attachment to the cranes as hooks, magnets, etc.

(a) At all times, whether carrying loads or not, hooks and chains should be kept high enough to clear men or apparatus below the crane.

(b) Blocks should not be lowered below a point where less than one and one-half turns of cable will remain on the drum.

10. It is not good practice to make side pulls. If they are permitted they never should be made by use of ladle hoist.

11. Prompt action is required to stop the descent of a load when the brake will not hold. If it should be necessary to apply power to a motor in order to stop the travel of a crane or the descent of a load the contact point of the controller lever should be moved for lifting or reversing as the case may require, one point only beyond the off position. If this does not give enough power then try the second point, continuing the movement one point at a time as necessity requires, but no more power should be applied than is actually required to bring the crane or load to a stop.

12. Two or more safety seal locks for locking switches open should be carried in crane cabs along with the tool equipment. These locks should not be used for any other purpose than to keep a circuit open when the closing of it might cause an accident.

(a) The crane operator should use a safety lock for locking the main switch open every time he leaves the cab to go on the crane runway, or out on the crane for inspection or to make adjustment of parts.

(b) The inspector should, in addition to notifying the crane operator of his intentions, use a safety lock for locking the main switch open, every time he goes out on the crane.

(c) Repairmen should in addition to notifying the crane operator of their intentions, use a safety lock for locking the main switch open every time they go on the crane. The foreman in charge of repairs should be responsible for locking open the main switch and all individual switches, while repairs are going on and for removing the locks when the repairs are finished and the men are off the crane.

NATIONAL IMPORTANCE OF ENGINEERING INDUSTRIES

During the past four years we have learnt more than in the previous four decades concerning the national importance of certain industries. When we say "we" we mean our legislative representatives, public men, and government officials, and possibly hundreds of thousands of toilers who earned their daily bread in industries of whose larger aspects or bearing they knew but little. Engineers as a body cannot be included in that "we," for large numbers of them, profiting from the nature of their calling, and from the stimulus that the greatness of engineering work imparts to the imagination, have known something of the value of their achievements to civilization and the general development throughout the world. It is satisfactory that, under the influence of the terrible events of the war, the necessity for deciding what is and what is not essential for the successful conduct of military and naval operations has brought both us and our industries under close examination. Engineering and engineering workers have emerged from the experience with such a testimony concerning their usefulness to the human race as should not only gratify them for the present, but should auger well for very many years to come. Nobody can read the reports that have been published during the last few weeks regarding the engineering, iron and steel, and electrical industries, and the measures that should be taken for safeguarding them against international competition after the war, without being impressed with the great importance of these industries to the nation and to the British Empire as a whole. It is not necessary to be an engineer, or even remotely connected with the industries, in order to appreciate how much they mean to millions of our population; therefore it is not unreasonable to hope that in the legislative and in political life, which have not in the past counted engineers among them in any fair proportion, there will be a desire to adopt as many as possible of the recommendations now advanced. The report of the Electrical Trades Committee occupies its opening pages with a fairly full statement on the national importance of the electrical industry, which, it says, has never been realized either by government or by the general public, with the consequence that both the industry and the country have suffered from legislative errors. It is even said that the loss sustained by the nation through failure to take full advantage of electrical progress is estimated by "witnesses of high authority" at not less than £100,000,000 a year, and it is added that that loss is preventable by concentrating generation under improved administration. The war is stated by the committee to have demonstrated the safety of the Empire to be dependent on the employment of electricity. What is meant by this is that the output of munitions in the great industrial areas could not possibly have attained anything like its present scale had not an enormous aggregate horsepower of electrical energy been available for the supply of power and light. "The emergency has proved the electrical industry to be a 'key' industry."

THE ELASTIC LIMIT

We have long held the view that only under special conditions and kinds of stress does the elastic limit form a proper basis for the proportioning of machine parts or the elements of structures. To this general rule the main exception is provided by the case of alternating stresses. Here the trend of experience gives support to the view that safety is to be sought by keeping the range of stress within the elastic range of the material. In some other cases it is also advisable to use the elastic limit as the basis for proportioning dimensions, since even though an excessive stress might not actually endanger the safety of the structure, the risk of a permanent set may be highly undesirable.

As instancing how little the safety of structures, strained in one direction only is dependent on the elastic limit, the bombs used by Professor Bridgman in his experiments on the behaviour of materials under extremely high pressures may be referred to. The process of producing them is described by Dr. J. Johnston in a paper published in the "Journal of the Franklin Institute." A block of steel, after appropriate heat treatment, is bored with a hole 1 mm. less in diameter than the intended final dimension. This is then filled with kerosene oil and subjected to a pressure of 20,000 atmospheres or more. This causes a bellying out of the hole, which is then reamed to its final diameter. Under this treatment the metal is so strengthened and stiffened that the bomb is capable of carrying repeated applications of pressures of 10,000 atmospheres or more. The leak-proof piston used with these bombs consists of a hardened steel plug finished a nice fit to the hole. This piston is packed by a series of washers, successively of rubber, copper, and of soft steel, which are followed by a hardened steel collar which takes the thrust of the ram by which the pressure is applied.

The methods followed by Professor Bridgman have, we think, a bearing upon turbine engineering. With the rapid increase in size and speeds the stresses on the wheels at the exhaust end of the turbine have risen greatly, and further progress may be checked if designers persist in estimating their factors of safety on the basis of the elastic limit. The stresses to which such wheels are subjected are nearly as steady as hydraulic pressures, and actual experience has shown that no permanent injury results even if the metal be strained considerably beyond its elastic limit. For example, at the Birmingham meeting of the British Association in 1913, Mr. Gerald Stoney recalled an instance in which a wheel intended to be run at 5,000 r.p.m. was by error tested at a speed of 8,000 r.p.m. The consequence was the bore stretched ¼ inch. No permanent injury resulted, however. The wheel was rebored and passed into service, where it proved quite satisfactory. An overstrained material requires some little time to recover itself, but as this was allowed in the above instance the wheel was probably stronger than before.—Engineering.

A COMEDY OF ERRORS

The Fire Marshal of the state of Wisconsin has issued a bulletin which he terms a "Comedy of Errors." It should have been called a tragedy. It says:

He looked for a gas leak with a match, and found it.

He lighted a match to see if his gasolene tank was empty. It was not.

He smoked while filling his auto tank, but will do so no more.

He smoked in bed; so did the bed clothes.

He threw the matches into the waste paper basket. He is wiser now.

He threw a cigarette stub into some rubbish.

He saved his oily waste and oily rags and they burned the shop.

He washed his hands in gasolene near the stove. The doctor washes them now.

He did not worry about fires as he had "plenty of insurance," and forgot the safety of his wife and children upstairs.

He stuffed up the chimney holes with paper and rags.

She cleaned her gloves with gasolene and saved fifteen cents, but paid the doctor and druggist fifteen dollars.

She poured kerosene into the lamp while the wick was burning.

She put gasolene into the wash boiler on the stove to make washing easier.

She dried clothes too near the stove.

She used the wrong oil can.

She burned sulphur all over the house to fumigate.

She used the wood-box back of the range as a waste paper receptacle.

She gave matches to her children to go out to burn leaves in the yard. The cotton dresses burned easier than the leaves.

She was "coming right back," so left the electric current on in her iron.

She swung the gas bracket too close to the curtains.

She fixed up a fine tissue paper shade for the lamp.

She filled the tank of her gasolene stove while one burner was going.

The comedies have turned to tragedies; many of the scenes of action were in ashes and too many of the actors are maimed or dead, more will follow, no doubt, as they are prone to ignore the advice and experience of others instead of profiting by their errors and sufferings.

It is not enough to be industrious; so are the ants. What are you industrious about?—Thoreau.

Laws Governing the Fluidity of Molten Cast Iron

Fluidity Depends on Several Factors Which Affect the Melting Point—The Author, in a Paper Read Before the British Foundrymen's Association, Explains Some of the Vagaries in the Operation of the Cupola

By MATTHEW RIDELL

THE many varied and widely divergent views which are held by experienced foundrymen concerning the correct construction and the proper manipulation of the cupola are too well known to need recounting. The mere fact that after so many years of experience and discussion there should be still such diversity of opinion on this topic is noteworthy. It would seem to indicate that either the cupola, or its process, is not the simple matter it appears to be, and that some more scientific explanation than common sense is required for the solution of the problem.

The fluidity of cast iron depends on the amount of superheat or number of degrees of temperature over and above its freezing temperature that has been imparted to it in the cupola. The greater the superheat the greater will be the fluidity or degrees of life possessed by the metal, and, other things being equal, the longer will it remain fluid to fill up the intricacies of the mold.

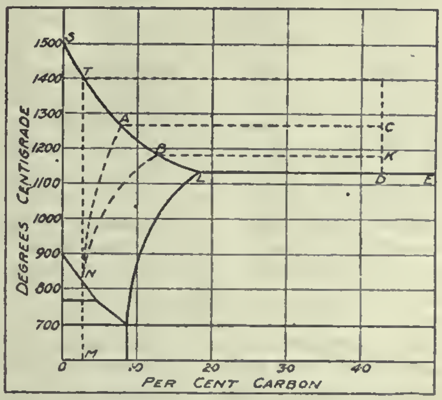
Dull Iron

When the metal runs dull from the cupola and is sluggish, its degrees of temperature or life are not far removed from the solidifying temperature. It is deficient in superheat. The reasons which one may hear ascribed in the foundry for the poor working of the cupola are many and various. Some blame the air supply as too great or too strong; others would have the quantity or pressure reduced; but the majority, recognizing that the coke plays a most important part in the production of heat, and knowing that the manager is prompted by considerations of economy in the use of this material, are inclined to conclude that economy has been carried too far. To these the sure remedy is more coke. It seems but natural to suppose that an increase of coke ought to result in a larger amount of heat being developed in the cupola. No doubt it does so result, but repeated experience shows that after a certain limit of coke in the charge has been reached further additions appear to make the metal more dull instead of more fluid. This and some other peculiarities of the cupola which seem to defy common sense explanations have for a long time puzzled the writer, and the solution herein advanced occurred to him while investigating the problem in connection with semisteel difficulties.

Among the peculiarities which the present argument appears to solve satisfactorily may be mentioned the following: Better results are obtained in securing hot metal when the bed coke is not well lighted above the tuyeres, before the blast is put on and the first iron takes longer to come down, than are secured when the opposite conditions prevail. Many foundrymen have noted this peculiarity, but explanations have not been satisfying. Also, it has been noted that foundry irons with high silicon are generally fluid, while those with high sulphur are inclined to be sluggish when melted under similar cupola conditions. It appears generally to be taken for granted that the actual temperature at the spout of these different classes of irons is the same, or approximately so, in all cases, and that the fluidity or sluggishness of the metal is due to some inherent quality of the respective elements—silicon and sulphur.

Not Satisfactory for Superheat

An examination of the cupola and of its load will show that as an instrument for imparting superheat to a molten metal it is as unsatisfactory an arrangement as could have been devised. It is divided into three zones, as follows: (1) The bed into which the metal flows as soon as it is melted; (2) the melting zone where the maximum heat is developed and the solid metal converted to the fluid state; and (3) the stack wherein the descending charge is being heated by the ascending gases.



EQUILIBRIUM DIAGRAM

From the foregoing it will be noted that the point at which the temperature is high enough to melt the solid iron is well removed from and over the basin or well into which it flows when melted. After the door of the cupola has been made up there is no combustion going on in the bed coke below the tuyeres and, therefore, no heat is being generated in that quarter. So soon as the metal reaches its melting temperature and becomes fluid in the melting zone it passes rapidly away from this high-temperature zone into the basin at the bottom of the bed. In some cases it passes out of the cupola altogether, and consequently cannot come under the influence of subsequent heat. What little superheat the metal may have acquired at the region of maximum temperature is largely discounted in its journey to the bottom of the cupola. Besides having to pass the tuyeres, which are discharging large quantities of cold air into the furnace, it will have to part with some of its heat to the coke which makes up the bed. If there was nothing more involved in the melting of metal in the cupola than the question of heat it would be extremely difficult to account for one kind of iron coming out more fluid, and therefore hotter, than an iron of a different class. Under similar conditions of melting all metals should have imparted to them the same degrees of heat.

It is a common belief that all substances which pass from the solid to the liquid state and vice versa make these reverse changes at the same temperatures. For instance, ice becomes water when the temperature begins to exceed 0 degrees Cent. and water changes back into ice as the temperature begins to be less than 0 degrees Cent. Every substance has its own melting and freezing points which are supposed to be identical for each substance. This assertion is true of all simple bodies or of alloys which retain their components in solid solution. It is because pig or cast iron is an exception to the rule that the cupola is practicable at all as a melting instrument. If any of the materials which adhere to the rule were melted in the cupola they would probably resolidify in the bed, or at the best would come out of the cupola so dull as to be useless for casting purposes owing to the lack of superheat or life.

To investigate the behavior of cast iron in the cupola and to ascertain, if possible, why it should be an exception to the general rule, it will be necessary to refer to the accompanying equilibrium diagram and the information it gives concerning the iron-carbon series of alloys.

The main fact to be noted is that both the melting and freezing temperatures depend on the amount of carbon in the alloy, that is, the amount of carbon in solution in the iron at the time. The lower the amount of carbon which is in solution the higher is the temperature at which the changes of state take place, The lowest freezing or melting temperature is at about 1130 degrees Cent., but it is only such an alloy as has about 4.3 per cent. carbon to 95.7 per cent. iron that will freeze or melt at that temperature. An increase in the amount of either of the elements in solution results in an increase of the temperature at which the changes take place, 4.3 per cent. is the saturation point of carbon in iron when these two elements are reckoned alone. With ordinary pig irons this figure obviously requires adjustment on account of the presence, in greater or lesser quantities, of other elements. For the purpose of the present argument it may be taken for granted that foundry irons contain very near the saturation amount of total carbon. If all the carbon of a 4.3 per cent. total carbon or saturated cast iron were in solution or combined with the iron, the metal should melt or freeze at about the temperature of 1130 degrees Cent. Fortunately for the reputation of the cupola the carbon in pig iron is found separated out as graphite as well as being in solution or combined in the iron.

Melting Temperature

As the melting temperature is determined by the amount of carbon in solution only in the iron at the time it reaches the melting zone, the free graphite is left out of account. It follows, therefore, that an iron which is very low in combined carbon, although high in total carbon, cannot be melted until a very high temperature is reached. The mass or body of metal will remain in the solid condition until the high temperature is attained, and consequently the liquid metal will be extremely hot. In the course of melting the free graphite is rapidly dissolved and enters into solution with the iron, with the result that the molten mass has a high percentage of combined carbon and therefore a low freezing point. Under such conditions an iron which will not melt until it has been heated to, say, 1400 degrees Cent., does not freeze again until the temperature has fallen to about 1130 degrees. Such a metal may be said to have 270 degrees of life and will appear fluid.

If, on the other hand, the combined carbon in the pig iron is already high, the temperature at which melting begins will be low, and even after the free graphite is dissolved will possess only a few degrees of life or superheat.

Another point which the writer would like to emphasize is that it is the amount of carbon in solution at the time the metal enters the melting zone and not necessarily that of the original iron charged into the cupola that determines the temperature which will be attained in the process of melting. It has to be borne in mind that after iron has reached a certain temperature much below its melting poin andt has been converted into gamma iron it dissolves carbon very readily. This implies that if in the course of heating, graphite is being reduced while the percentage of the combined carbon is increasing in the iron, the melting point will be lower than indicated by the original analysis. It is obvious that in order to obtain the hottest melted metal it is essential to get the unmelted iron into the melting zone as quickly as possible. The absorption of the graphite is not instantaneous, but the rate at which it takes place increases as the temperature rises. When, therefore the descent down the stack is slow and the metal is held above the melting zone through excessive coke in the charges, the iron is afforded an opportunity to dissolve the graphite, with the result that the material enters the zone with a lower melting temperature than it otherwise would have had. One can see from this an explanation of why excess coke results in duller instead of more fluid iron. The same explanation applies to the bed coke. If this is too high, or if the bed is so burned up that the metal is brought to a red heat, in many instances little short of actual melting, before the blast is turned on, the amount of graphite that has entered into solution will be considerable, and the pig will melt at a comparatively low temperature. So long as the first charge is resting on coke which is not yet alight when the blast is turned on, its combined carbon is unchanged, and the quick combustion of the coke by the blast raises the maximum temperature in the cupola before the absorption of graphite has been able to proceed along very far.

The theory likewise explains the reason of the differences in the fluidity of siliceous irons, as it is only necessary to take into account the accepted actions of silicon and sulphur with regard to the solubility of carbon in iron. Silicon by reducing the solubility makes it more difficult for the graphite to become absorbed while the temperature is being raised, while the influence excited by sulphur is all in favor of combined carbon.

Source of Superheat

In a previous paper on the subject of semi-steel, the writer, arguing from the equilibrium diagram, advocated the use of high carbon steel, such as files, etc., because of the greater ease and lower temperatures at which such material could be melted. Experience has proved that the results to be obtained from mild or low carbon steel are superior to those which the use of files will afford. Does not the theory here offered suggest an explanation in that the question of superheat and its source was overlooked? The high carbon steel with all the carbon in the combined form would have a lower melting temperature than the pig iron itself, and its influence would be to impart a dullness to the molten mass, and so render its homogeneity more uncertain. In the case of phosphoric irons. in which the fluidity is such a marked feature, it is necessary to look to the diluting effect of the phosphide eutectic. The phosphide eutetic becomes fluid at about 950 degrees Cent., and so long as it remains entrapped in the otherwise solid metal it is acquiring superheat and increasing its fluidity accordingly. As this phosphide eutectic may constitute 15 per cent., or even more of the mass under treatment, the diluting effect of such a considerable volume of highly fluid material is manifest.

Conclusions Reached

The foregoing statements may be summarized briefly as follows:

The fluidity of cast iron depends on the degrees of heat which it has attained in excess of the freezing temperature.

The cupola is not suited to impart directly superheat or fluidity to any material which is being melted therein.

While the freezing temperature of foundry irons for all practice purposes, may be taken as constant, at about 1130 degrees Cent., the melting temperature varies, and is regulated by the amount of carbon in combination or solution when the material enters the melting zone.

In view of the gradual absorption of carbon into the iron as the temperature rises the practical conclusion suggests itself that in order to obtain the molten metal in the most fluid condition the solid material in the cupola should be introduced into the melting zone as quickly as possible.

Excess of coke in the charges, too much coke in the bed or too fierce burning of the bed before blast is turned on must result in dulling the iron.

Equilibrium Diagram

On the accompanying diagram an attempt is made to illustrate graphically the principal features of the foregoing remarks. SLDE is the solidus curve of the equilibrium diagram. Any alloy of iron and carbon whose ordinates of concentration and temperature intersect below the curve can normally exist in a completely solid state. Before the alloy can become in any way liquid the ordinates must intersect above the solidus curve. Above SDE the alloy is completely liquid and begins to solidify, when the ordinates of concentration and temperatures intersect on the curve.

The dotted curves represent the melting and freezing processes of an iron with 0.3 per cent. combined carbon, 4 per cent. graphite carbon, the balance of 95.7 per cent. being assumed to consist of iron only.

If the temperature of the solid metal is raised without change taking place in the carbon arrangement it will attain to 1400 degrees Cent. before the metal will begin to melt, as indicated by the dotted line MNT. The curves MNA and MNB show the difference brought about in the temperature at which the metal begins to melt. through free carbon being absorbed in solid solution in the iron while the mass is accumulating heat. After the temperatures TAB have been acquired, and as the metal melts the remaining free carbon is rapidly dissolved as indicated by TF, AC and BK. The liquid solutions each containing 4.3 carbon in combination have temperatures F, C, and K, respectively, but all begin to freeze at the same temperature D (1130 degrees Cent.) The superheat or fluidity of the first is FD, which is greater than that of the second, CD, and still greater than that of the third, KD.

Importance of Diagram

Dr. W. H. Hatfield complimented the author on the development of the equilibrium diagram, adding that he entirely confirmed what Mr. Riddell had said concerning its importance. From the metallurgical standpoint it was impossible to understand the properties of cast iron until the diagram had been properly studied. Prior to writing his book on Cast Iron Dr. Hatfield spent three years in following through the evolution of the diagram. However, he was unable entirely to follow Mr. Riddell in his deductions. The diagram was constructed on cooling curves of alloys containing from nothing to 5 per cent. of carbon. Mr. Riddell had been deducing his conclusions from the properties of low carbon alloys, namely, steel containing 0.2 to 0.9 per cent. of carbon. The term equilibrium must first be understood, added Dr. Hatfield. It means that if an alloy is maintained for a sufficiently long period at a certain temperature certain phases or conditions will be realized. The D point on the diagrams is the eutectic and if 4.3 per cent. of carbon is in a carbon alloy, freezing would take place at about 1130 degrees; but in ordinary cast iron containing from 1 to 3 per cent. of silicon, the freezing point of the iron is modified. The first results of added silicon is to reduce the solubility of carbon. If an iron containing 3 per cent. of silicon with, say 3.2 per cent. of carbon was gradually raised in temperature it would be found that the carbon absorbed would be in conformity with the diagram. Dr. Hatfield could not agree with the theory that with the cupola it is possible to heat a piece of cast iron to a temperature so high as had been indicated without fusion taking place. He suggested that Mr. Riddell reconsider his theory in the light of the suggestions offered and he thought he would find that equilibrium would be attained much more readily than was stated in the paper. In actual foundry operations ordinary foundry iron containing 1.5 per cent. of phosphorus could be melted in a much shorter time than Mr. Riddell had said, and the smallest articles could be cast therefrom, the degree of superheat being sufficient.

Experiments in Melting Iron

Mr. Riddell said that his equilibrium diagram was built-up in the simplest possible way and he did not believe that the changes took place so rapidly as Dr. Hatfield indicated. He had personally conducted some experiments in melting crucible iron at different rates in order to ascertain the temperature to which he could raise it before it became fluid. But he agreed that the presence of silicon reduced the rate of progress and promoted fluidity in cast iron.

Hot Iron Soft

R. Carrick said he would like to draw attention to certain statements made by Dr. Hatfield. Although he was not a metallurgist he had made thousands of practical tests of cast iron and he had never yet found that the higher the temperature of cast iron the more likely hard iron was to be obtained. He thought Dr. Hatfield might offer, at some future time, a further explanation. Mr. Carrick had tested for hardness with the Brinell and other machines and his own experience certainly did not confirm that statement. He thought most foundrymen agreed that the hotter they cast the iron the softer it would be. Leaving aside the question of chemical content he thought mechanical tests would confirm that theory.

Effect of Temperature

Dr. Hatfield replying to further remarks said that his statement with regard to the effect of temperature was based upon actual experiment and observation, and many of those experiments could be easily carried out. He had found that iron cast hot was distinctly harder than iron cast cold. He could give actual experimental data in support of that statement. His experiments consisted of a gradual increase in the silicon content and he really did the work primarily to see how the results compared with those published by Professor Turner in 1881. He increased the silicon content by stages of 0.25, 0.50 and 0.75 per cent. up to 3 per cent. of silicon, and then he determined the result by fracturing the casting and testing both the combined carbon and the mechanical properties. One thing he discovered was that the gradual addition to the silicon content did not result in a gradual precipitation of the graphitic carbon. In his remaining series of experiments he found that the combined carbon remained at a high maximum well over 3 per cent. until a certain silicon content was reached, and then he found a rapid drop. In that series the casting was done at a fairly cold temperature. In the next series with the silicon contents identical he cast much hotter and he found that the combined carbon persisted until the higher silicon content was reached and that was confirmed over and over again in works practice. If they had a very heavy casting with a sufficiently high silicon the effect of casting temperature would be different because they would always have a maximum softness.

F. J. Cook said that Dr. Hatfield's concluding remarks contained the crux of the whole subject. It was not only a question of hot or cold casting temperature, but also a question of the rate of cooling. When dealing with hard iron which cooled quickly, as for superheated steam engine cylinders, the metal was susceptible to hardness and, therefore, susceptible to the influence of the rate of cooling. If they were not careful they got very hard iron before they were aware of it. If the range of cooling was increased the possibility of softness was increased. He did not wish to throw doubt upon what Dr. Hatfield had said, but personally he had cast thousands of cylinders and there was no doubt that in casting cylinders with metal of the kind he had described at a high temperature they would be more easily machinable than if cast with metal of the same analysis cast cold. That was due simply to the different rate of cooling rather than temperature effect.

SUBSTITUTED METALS IN ELECTRICAL ENGINEERING

A German technical contemporary has been giving some interesting details of the shortage of metals within the German borders, and the steps taken to remedy the evil in the electrical industry. Attempts have been made to expand the restricted supply of zinc by adding other metals, but iron has not given good results. In any case the alloy must contain about 90 per cent. of zinc, and not more than 3 per cent. of aluminum can be added without the risk of pitting. A zinc alloy containing about 6 per cent. of copper and 3 per cent. of aluminum has been found as a suitable material for casting for many purposes, though not for constructional work. For galvanizing with zinc, Schoop's process is used. The melted zinc is sprayed by means of compressed air (3½ atmospheres) in an atmosphere of coal gas on to the iron, which is heated to 70 deg. or 80 deg. Cent. The process may also be available for applying coatings of aluminum, tin, copper, and some other metals. The consumption of tin in Germany is about 21,500 tons per annum, about 70 per cent. of which is lacking, after taking into account the tin recovered from tin-plate waste, etc. For the delivery of this tin treatment with dry chlorine gas has proved the best method, since it converts the tin into chloride without materially attacking the iron. As a substitute for ordinary solder a mixture of 10 per cent. tin, 10 per cent. cadmium, and 80 per cent. lead is recommended. More recently a cadmium solder containing only 2 per cent. of tin and an antimony solder free from tin have been prepared. In 1913 the world's production of aluminum was 78,000 tons, of which Germany produced 15,300 tons. The impurities in the metal, mainly calcium anl aluminum oxide, have now been reduced to about 0.4 to 0.5 per cent. The copper for electric cables has now been replaced by a steel core round which are twisted six aluminum strands. Iron has also taken the place of copper for electro blocks for illustrations, and prophoric alloys containing about 30 per cent. of iron are used with tinder as a substitute for matches.

DEVELOPMENTS IN SHOP EQUIPMENT

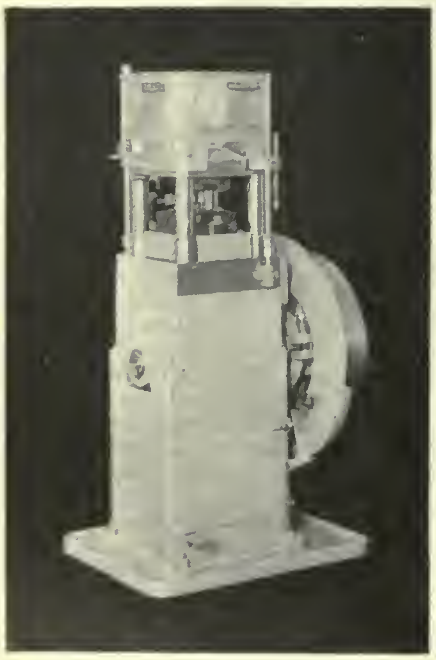
Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.

THE WRIGHT DIEING MACHINE

THIS is a new design of machine for blanking, piercing, forming, coining or drawing sheet metal, made by the Henry & Wright Mfg. Co., Hartford, Connecticut.

There being no torsional or ripping strains throughout the machine, the strains being wholly tensile and compressive, the danger of injury to the machine through overloading is almost entirely eliminated; and on account of the fact that it is impossible for the dies to be thrown out of perfect alignment with each other, they should last several times as long as usual, remain sharp for a longer period, giving more perfect edges to the work and in blanking eliminating burrs to a great extent.

The driving mechanism is all located below the die plates instead of above as on the older machines, thus not only doing away with the great obstruction to light, which has always been a fault with these machines, but the machine is in better balance and can be constructed with very much less weight for the same strength as heretofore.



SAFETY CAGE RAISED SHOWING PUNCH AND DIE.

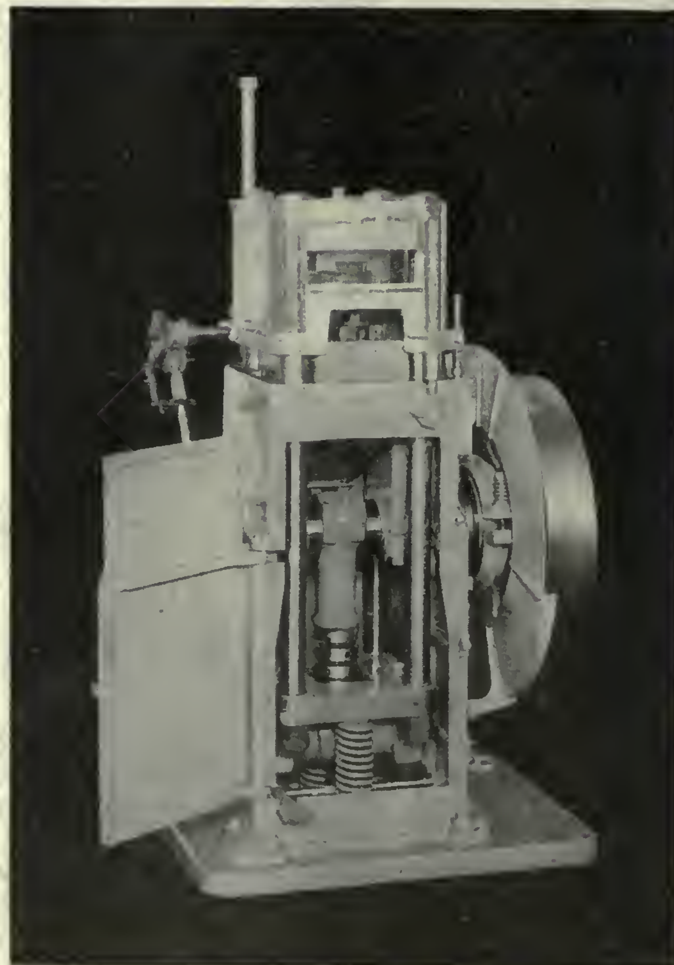
The illustration shows the side view of the machine with the door open, exposing the internal mechanism.

While a simple crank shaft is shown here the patent covers any kind of eccentric mechanism such as a knuckle joint, eccentric train of gears, a cam or any of the known forms of eccentric motions.

This picture also shows the bearings which consist of four inserted bronze bushings at the top of the machine and two cross head guides at the sides of the lower plate.

Springs are also shown which, while not essential, help to make the motion of the machine much smoother than otherwise.

Felt protected dust guards surround each of the four shafts and liberal oil cups are provided within easy reach throughout the machine.



SIDE VIEW OF PRESS SHOWING OPERATING MECHANISM.

The chute is covered with leather in order to deaden the sound of the blanks falling into the chute to a minimum. The design of the machine lends itself easily to the use of various attachments such as finger motions, automatic feeding mechanisms, scrap cutters, dial feeding devices, etc.

As will be readily seen the posts form a natural hub for the attachment of dial feeding devices and there are many ways in which these machines, on account of their very compact design, may be used in groups to advantage over other machines such as the placing of a line of machines under a bench of the height of the dies and run by belts attached to pulleys on a line shaft underneath the bench.

The safety device consists of a cage, shown in illustration, which fits entirely over the top of the machine and this cage must be raised in order to get a hand or finger between the dies and when so raised the machine is locked so that it cannot operate until the cage is lowered, in which position it is equipped with holes sufficiently large for the metal to be operated upon to enter, but not large enough for either the entrance of a finger or hand.

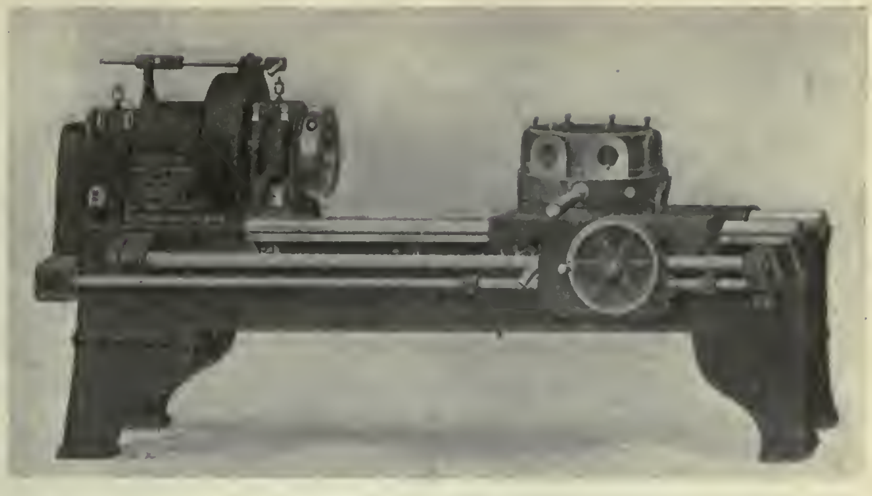
The machine may be operated either from a sitting or a standing position, and the dies may be fed from either one of the four sides as against one or two sides in other machines.

The weight of the number one machine is 1350 lbs., and its rated capacity, 25 tons.

This machine is the latest production of the Henry & Wright Mfg. Co., Hartford, Conn.

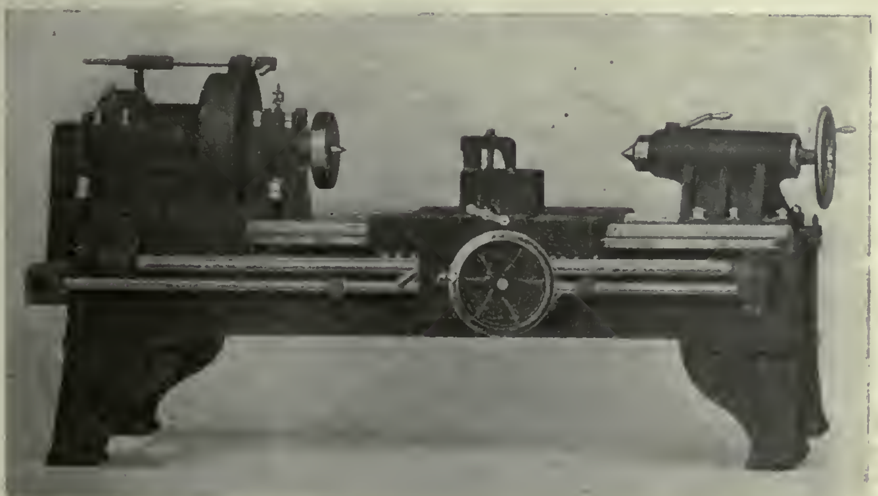
SHELL LATHES

The new lathes illustrated herewith have been designed especially for the heavy work demanded in machining ammunition and are particularly adapted to the machining of 155 MM. and 6 in. shells of class B steel. They are lathes of medium swing and high power, producing a product free from irregularity and with a smooth accurate finish.



SHELL BORING LATHE

The head stock is of the same general design as that of the original Hindman class A lathes. A few changes have been made in this construction which, however, give increased strength and power drive, can be direct from a line shaft through countershaft or the lathe may be fitted for motor drive. Both the shell turning and the shell boring lathes which are illustrated, can be furnished with the single belt drive, tight and loose pulleys running at a speed of 690 revs. per minute and a five inch belt. The loose pulley is fitted with roller bearings and is smaller in diameter than the tight pulley, thus relieving the strain on the shafts when the machine is idle. The spindle is a hammered steel forging, heat treated and ground and is lubricated by means of a well in each cap in which is a sight feed oiler and from which wicks lead from the spindle bearings surface, generously lubricating at all times. The apron is of ample size. This apron contains only two gears which control the hand operation of the carriage in both directions. The operating lever is located at the extreme left of the apron and quick return is accomplished by throwing the operating lever into reverse after shifting the belt from the tight to the loose pulley by means of the lever located at the top of the head strap. By this arrangement the main spindle comes to rest while the machine is operating. The shell boring lathe is of the same general design in some respects as the shell turning lathes but is fitted with a large spindle with a 7½ in. hole which permits the 155 MM. and 6 in. shell forging to be admitted in practically the full length.



SHELL TURNING LATHE

The front of the spindle is designed so that the large screws can be used to hold the shell instead of chucks. This machine is furnished regularly with the six-way turret of simple construction and provided with a powerful and rigid lamp over the entire surface of the turret base. This is sufficient to hold the turret under the heaviest cut. The turret head is of steel casting of ample size to stand all strains.

These shell lathes as described are manufactured by the Duff Manufacturing Company, Pittsburg, Pa.

DRAUGHTSMEN AND FOUNDRY PROBLEMS

By D. S.

The necessity for draughtsmen and engine designers exercising greater care in the design of casting parts of machinery was pointed out by Mr. J. Shaw in a paper read recently to members of the Newcastle branch of the British Foundrymen's Association. The author, in his paper, dealt with the difficulties and worry with which the foundryman had to contend with in the moulding and casting of complicated parts in order to minimise the local internal straining actions set up, due to unequal cooling in the mould. This point is not appreciated as it might be by many draughtsmen in their designs, with the result that many castings of doubtful reliability are made owing to possible internal strains, caused by lack of harmony in their constructive elements. Any sudden changes from uniformity in thickness of metal should be avoided as far as possible; where variations in thickness occur the thicker portion is the last to set and acts as a feeder to the other parts, causing sponginess in the thicker section. Simplicity in structural design should be aimed at in order to reduce the cost of manufacture. The author dealt with the responsibility of the drawing office in facilitating the output in the foundry; considerable thought had in the past been given to decreasing cost and speeding up of work in the fitting and turning shops, but a knowledge of foundry work was essential in order to obtain the best and cheapest castings.

The best preventive of loss in coal storage is to inspect the pile regularly. If the temperature reaches 150 deg. Fah. the pile should be carefully watched, and if the temperature rises to 175 deg. or 180 deg. Fah. the coal should be removed as promptly as possible. The coal should be thoroughly cooled before being replaced in storage.

* * *

A VALUABLE rust-inhibitive coating for general priming of finishing work may be prepared from sublimed blue lead. The use of two parts of blue lead and one part of linseed oil containing about 5 per cent. of turpentine drier makes a paint of the right consistency. This may be purchased in prepared form. When this paint is used for top-coat work in marine exposures—battleship gray—the addition of 1 per cent. of carbon black to the blue lead aids in the maintenance of the colour. The rust-inhibitive value of this pigment is due to the high percentage of lead oxide litharge.

The Foremen That Are Wanted

HERE'S a rather unusual advertisement that appeared in the advertising columns of this paper:

"Foreman wanted for stamping and drawing department, also one for art metal department. Men with technical ability who are willing to keep up-to-date by reading the technical press preferred."

Rather unusual, isn't it? You never read an ad. where a man was wanted for a responsible position "who reads all the new fiction and is thoroughly familiar with the sporting pages."

It's just a good plain indication of the drift that has set in aimed at hundred per cent. efficiency. Firms realize that methods that were fine when their mechanics learned their trades are rusty with age now and as obsolete as a good, old-fashioned pumpkin pie. They want men in their more responsible positions who are keeping up to the newest developments. If there is a new method of performing a certain operation brought out, they want their men to know it. If there are parts of their plant that have served their day and generation and are not capable of keeping up with the competition of more modern plants, in justice to their own trade they want to know it. They cannot know it if the men in their plants do not keep up to the minute. And there's only one way to keep up to the minute, and that is by reading the trade and technical papers.

There are scores of good mechanics in responsible positions who read papers such as CANADIAN MACHINERY. They read the ads. as well as the other pages and they do so with good reason. The advertising in this paper gives them a line on all the new machinery that comes out, and there is always material with it of a descriptive nature that describes just why the machine is good and why it should supplement others that have been on the market.

After the war, more than ever, Canada will need efficient men to man our shops, if we are to hold our own in the commercial war which is almost sure to follow. Manufacturers owe it to the nation as well as to themselves to produce men as highly skilled and educated as possible. And the mechanics no less should be on the alert, quick to study and assimilate information pertaining to modern practice and new equipment.

It cannot be expected that present high wages will continue after war business is over. The race then will be not so much to the physically strong as to the mentally fit.

What Kind of Horse Will You Eat?

AND now there's a good-sized agitation on to have horse meat sold in Canadian stores. The supposition is, of course, that after being sold from the stores, people will eat the horses.

Well, if we're going to eat the nags let's get off to a good and proper start, thusly:—

Undertakers and pacifists eat black horses.

Sailors eat bay horses.

Orangemen, be sure to ask for a wing roast from a white King Billy horse.

Designers or draughtsmen insist on getting your cuts off a draught horse.

Shipbuilders should find out the days when their favorite shop will be able to serve them with a chunk off a good old worn-out Clydesdale.

By all means if we're going to eat horses, let's go at it right. Get the bit out of your mouth and the blinkers off your eyes and buy intelligently.

U. S. Govt. Tackles Labor Problem

STRIKING machinists at Bridgeport, Conn., refused to go to work following a board of arbitration considering their case. The result was the adoption of federal control of labor. This means in short:

(1) The Government will take over and operate plants where employers decline to abide by awards of the War Labor Board;

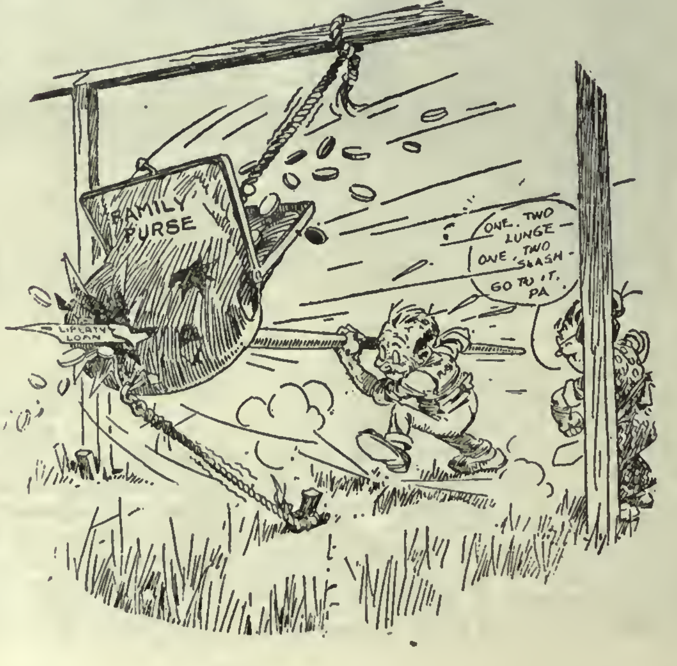
(2) Striking employees who ignore these decisions must return to work or be barred from any war industry shop in the country.

As the war industry shops are the only places protected by the Government against the draft, it means the putting into force in reality of the "work or fight" principle.

It takes a courageous Government to tackle a labor problem. The reason is clear: votes are at stake, and to the average government the next election is the greatest thing in the world.

In Canada we have had for a long time a surplus of arm waving, fist shaking and tub-thumping, but mighty few brave, disinterested moves having in view simply the welfare of the community at large. United States has gone in where Canada fears to tread.

ORDERS have gone out that no more beer is to be made in U. S. after Dec. 1. Old John Barleycorn has been steam rollered, assassinated, murdered and buried. And yet folks seem to collect enough stuff under the belt occasionally to make 'em wobble.



Chasing Up Produce Prices

HERE'S a clipping from a Toronto paper in reference to the Saturday market in this city:—

> Butter and eggs were plentiful, but Madame Farmer is fast raising the prices in order that they will reach the $1 a dozen price by Christmas. Eggs were 55 and 60 cents a dozen, while one woman who had a basket of large-sized ones asked 70 cents.

The government can regulate the price of wheat, of steel and many other lines. It can tell the steel mills what they can charge the jobbers, and the price the jobbers can charge the consumer.

But the price of butter and eggs jumps every time the old hen cackles and every time the hired man puts the three-legged stool down beside the brindle cow.

It may be that the man in the city does not understand the problem of the man on the farm. But it is painfully certain that the farmers are out of touch with the situation of the limited purse in the city when they persist in regarding the basket of produce as a blunderbuss in their hands to chase prices still farther up the high price tree.

Be a Tin Can Patriot

THE tin can has come to be quite a topic of conversation. There used to be the tin can that was tied to the dog's tail, and later there was the tin can that served in the shinny school where the hockey stars of later days were turned out.

But the tin can isn't nearly as important as the tin that's in it.

So the can's being tied on the tin can.

Every time you buy something in a wood or board container that used to be done up in tin, and don't grouch about it, you've become a tin can patriot.

And every time the tin can patriots save 1,000,000 two-pound tin cans they've provided the material for a mile of 85-pound rails.

So if you can not do anything more dazzling you can be a tin can patriot.

The policemen in Toronto are going to form a labor union. Well, why not make it a branch of St. Patrick's society?

* * *

They may cut off the supply of cars, and they may stop runnin' them, but don't worry. You'll soon be able to crawl down the cellar stairs and keep in form by cranking the furnace.

* * *

IN an election at Canmore, Alberta, an Austrian defeated a returned soldier in a school trustee contest, and there was only a sickly looking attempt to conceal the jubilation of the foreigners at the win. And it must be remembered that it is on this foreign labor that the West is depending for its supply of coal.

* * *

THE manager of one of Toronto's restaurant concerns stated that under the new food regulations they would save 50 pounds of sugar per week. Very nice. But is that taken to mean that the restaurant keepers will simply buy that much less and sell their meals at the same old price? If so the restaurant keepers will have cause to rise up and call the Food Controller blessed.

* * *

THERE is an agitation on to raise the price of milk in Toronto to 15 cents per quart. Farmers say they are not making money at present prices. It beats the band how farmers keep on paying off mortgages and buying motor cars and all the time losing money. On the dead level if there's a farmer who will own up to the fact that he's makin' money, will he please stand up on the bench so we can all have a look at him.

They Tied a Can on Him

HE learned his trade long years ago inside a little shop, he graduated with a whirl, a skip, likewise a hop. He was a dandy in his day, he learned things powerful quick, they 'lowed he'd slide along in haste and show them all a trick.

He knew about a lathe, he did, this whistlin' chap called Bill, he knew about a planer and he knew about a drill.

He learned the good old ways, he did, of doin' this thing and that, and stowed his knowledge in his dome way up beneath his hat—and he reckoned that the way he knew was quite the best on earth, and things he didn't know or do had neither good nor worth.

And so he went into the world to earn his daily bread, by sellin' out to other folks the stuff within his head.

But he didn't stop to grab no more, he didn't seem to think that stuff he learned long years ago might soon be on the blink. He hee-hawed at the chaps who worked and read books in the night, that they might keep their notions straight and know what things was right.

He had a snort for every kink that brighter minds had made, he wouldn't budge from what he learned in pickin' up his trade.

And other chaps went past this jay, they had the quickest way, and they'd do in just an hour or two what he'd fuss at all day. And yet he wouldn't take the choke and get himself in shape, he was just standin' still, by heck, this wise and knowin' jake.

This thing went on for years it did, he wouldn't budge an inch, he wasn't wise enough to see the comin' of the pinch. The firm he worked for watched this jay, he'd neither go nor vim, so they came along one day, they did, and tied a can on him.—Ark.

We've been saving daylight all summer, but we'll be blowed if we've got any more of it now than when we started.

* * *

SUGAR regulations have it now that one spoonful must do a meal. All of which makes us long for the good old days when we used to chuck in three heapers and then make a small whirlpool in the teacup to dissolve the stuff.

Kaiser to Austria—Now then, up you go.
—Punch.

MARKET DEVELOPMENTS

Much Harder to Secure Material at U.S. Mills

Canadian Warehousing Interests Are Running Pretty Close to Depletion in Spots—Big Orders in Montreal Will Call For the Erection of a Million Dollar Factory

THE placing of new orders in Canada for munitions, ordered by Washington, again brings this business prominently to the front. It is hardly necessary to do this, because the munitions operations comprise the greater part of the industry now moving in the Dominion. New contracts in Montreal will amount to about ten million in one shop, and a million dollar structure will be rushed up to house the new undertaking. Canada is moving in millions at present in a way that would have seemed impossible a few years ago. The capital expenditure in this case will be guaranteed by the government placing the business.

Things are not bright for Canadian firms securing material from U. S. points. Several of the largest houses in Canada that are in the warehousing line have had men at the U. S. mills trying to find out where they were at and they received very little satisfaction. As a matter of fact Canadian jobbing trade has now to depend largely on the connection it has built up with United States mills in years gone past. The rating given this class of trade is B-4, and that means practically nothing at all in the way of compulsion or obligation that the mill can be held to. There will have to be a more definite understanding soon. Canadian trade in sheets is being supplied largely from the smaller mills in United States that cannot be taken off sheets and turned over to plate because they can't roll anything but sheets. As a matter of fact these places are in better shape to make money than the big mills that can be converted to plate rollers.

There has been another cut made in the amount of basic material that can be turned over to the tin mills. There is a great need for rails at present. The war and the work at the mills follow very closely together. There is a feeling that there will be a big call for rails on account of the advance of the Allies, and the need for bringing up heavy artillery. Therefore every energy is bent at American mills to the turning out of rails. Every time they succeed in saving the material that would go into the making of a million two-pound tin cans they have provided for the manufacture of a mile of 85-pound rails.

Trade is brisk in supplies. There is small chance of any house accumulating a surplus of high speed steel at present demand. Prices remain firm, but have not gone up. In fact there has not been an outstanding price change during the week.

BIG ORDER FOR MONTREAL GIVES NEW START TO BIG BUSINESS

Special to CANADIAN MACHINERY.

MONTREAL, Que., September 16, 1918.—Further stimulus was given to the munitions activity during the past week by the announcement that one of the large local plants had just received a contract from the American government for large shells, the value of which will run close to $10,-000 000. The new addition that will be required will entail an expenditure of about $1,000,000, this to be guaranteed by the U. S. government. It is not unlikely that other contracts may be given to those firms in a position to manufacture the desired shells on a stated basis of production. These developments have acted as a stimulant to trade generally and business shows improvement in many directions. Dealers in machine tools report a noticeable increase in enquiries and sales have been better during the week. Difficulty is still experienced in obtaining equipment from American points, particularly in those tools used for the manufacture of munitions. Trading in old materials has been remarkably quiet, no doubt as a result of present festivities in connection with the Jewish New Year.

Steel Shortage Still Pronounced

The general steel situation is still marked by the evident shortage of material and possible relief in this connection is very uncertain owing to the excessive requirements for essential war purposes, at least this is the argument invariably advanced by the producer when orders are placed at the mills. With the possible exception of some of the lighter and lesser used shapes the dealers' warehouses are almost depleted of material and ruling regulations hold out little hope of acquiring stock for early future demand. This condition will eventually result in many essential war undertakings finding it very difficult, if not impossible, to obtain steel for emergency repairs or alterations. This is a feature equal in importance to supplying material for manufacturing purposes, as the latter cannot be achieved unless the former is taken care of. Steel shipbuilders are obtaining supplies in fairly large volume but not in sufficient quantities to meet maximum requirements. Transportation conditions at the present time are quite satisfactory and delays are more a question of production than railroad troubles.

Speaking on the fuel situation one large dealer here stated that conditions this winter would in all probability be less acute than those experienced last winter owing to the better organization of railroad facilities for handling the country's business. The uncertain factor appears to be developments that might arise at the mines that would result in reduced output.

Steady Tone in Metals

With the exception of tin the metal situation is steady in character with the demand normal and the supply adequate.

Copper continues firm at the set price of 31 and 32 cents per pound. Tin is coming through in greater quantities and increased regularity, and in consequence the situation is showing marked relief with prices declining; dealers are now asking 95 cents to $1 per pound with still lower levels in prospect.

Supplies of spelter are equal to the demand and prices are steady. Lead is strong with the supply light and quotations are very firm at 10½ cents per pound. Antimony and aluminum are firm and unchanged at last week's quotations.

Interest Renewed in Machine Tools

As a consequence to the placement of additional large orders for American shells, the renewed interest that has apparently developed in machine tools has been a feature of the week's transactions. Inquiry for new equipment has been quite pronounced and the demand for used machinery of a shell making character has shown an increase. Conditins in the States make it increasingly difficult to place orders and definite delivery is next to impossible. Many Canadian tool builders are so filled with regular business that special work in the way of shell machinery cannot be accepted. Increasing demand for machine shop supplies is a steady factor of present activities. The sales of high-speed and other tool steels have been a little lighter but the average is well maintained.

Little Doing in Scrap

An influencing factor in the present quiet condition of the old material situation is the New Year celebrations of the Jews, an event that generally prevents ordinary activity in this line. Trading is about normal with the bulk of the business in heavy melting scrap and machine cast iron, the latter, however, very often hard to obtain owing to the heavy requirements. Much of the scrap in connection with the production of munitions seldom passes through the hands of the dealers as the producer of scrap in many instances is also the consumer, and where this is not the case the material is shipped direct to the furnace plant without the intermediate handling by the dealer. Prices have shown some slight fluctuations during the week but generally quotations are the same as last week.

POINTS IN WEEK'S MARKETING NOTES

The most conservative estimates in U. S. place the steel shortage for the last half of 1918 as four million tons.

Big wire plants are being remodelled in order to produce shell rounds instead of wire rods.

A large number of rails are being called for in U. S. war plans, this leading to the belief that a considerable advance is planned which will call for rails to carry up big guns.

Tin plate mills have been informed that they must cut down 30 per cent.

Canadian warehouses are given a B-4 rating by U .S. mills, which carries no obligation on the part of the mill.

U. S. mills rolling sheets have been ordered to still further reduce the amount of material they are taking from the furnaces for this purpose.

General Pershing calls for 100,000 3-inch shells per day. This is in addition to the volume of munitions business that is being carried on.

Strikers in U. S. war shops who refuse to abide by the decision of the War Labor Board are barred from working in other war work plants. Firms refusing to accept awards or refusing to meet their men will have their plants taken over and operated by the U. S. Government.

KINGSTON'S GAS TANKS NOT UP TO CAPACITY

And There Are Prospects of a Serious Shortage There During This Winter

Kingston is confronted with an uncomfortable gas situation. The present storage facilities are inadequate, as can very easily be understood when it is realized that they have not been increased for more than ten years. A new gas holder was to have been in operation last December, but owing to war conditions affecting labor, the contractors failed to fulfil bargain to have the excavation completed at a certain date, and the Utilities Commission, acting under the advice of its expert, Frederick Burnett, of Toronto, refused to permit the concrete work to be proceeded with lest it be damaged by frost. General Manager Folger then has to juggle along as best he can to supply the people with gas throughout the winter and spring. The work of constructing the concrete foundation of the gas tank was proceeded with late in the spring, but when the concrete was tested it was found to leak, and the Commission refused to accept it. The contractors have now lined the interior of the tank surface, and are satisfied it will stand the water test, but it appears doubtful if the Commission will accept a patched piece of work. If it does not accept it, the concrete will have to be blown out and replaced, and several months will be lost, precious months, for fall is at hand. To tide over another winter with the present gas facilities is going to be some job. The people had a taste of gas shortage in early September, when the supply gave out Friday evening at six o'clock, and continued off until Saturday morning.

CANADIAN STOCKS MAY YET RUN LOWER

U. S. Points Not In a Position To Send More Material to the Dominion

TORONTO.—Some Canadian dealers who have been at U. S. points do not bring back glowing reports of the chances of this country receiving increased supplies of raw material from United States points. The war program at Washington is staggering in its size, and compelling in the way in which the authorities are adhering to it. This program has precedence over all else, and it means that unless production is greatly increased the war appetite is going to crowd some of the less necessary business into the ditch.

Shell plants in Canada on American business are doing well in the matter of deliveries, although there are a number of places where operations are not yet under way.

Condition Is Not Hopeful

Those Canadian firms or houses that have been looking forward to something beter in the way of supplies from U. S. points have been living in a false atmosphere. The plain fact is that the war program of United States increases every twenty-four hours. The war looks bigger to them every day, and they are expending their war orders in proporions in keeping with this view.

Mr. Near, of Drummond-McCall, spent the greater part of last week at U. S. mills from which they have for years drawn a great share of their stock. 'Things are looking worse than I ever anticipated," remarked Mr. Near to MACHINERY. It seems to make no difference whether an article is on the embargo list or not, the government has its eye on it all the way through, and is determined to see that it goes to a war purpose shop and no place else. Previously Canadian warehouses have been getting sheets lower than 1-8" quite readily, but it seems unlikely that this condition will continue for any length of time. The best rating that is given to warehouse orders is B-4. They give that rather than a direct turn-down. A B-4 rating depends entirely on your connection with the mills. As a matter of fact it is becoming a saying among the mill men when they are approached by the warehouse men 'I have an A-1 desire to serve you but only a B-4 ability.' The arrangement as it stands at present gives the advantage entirely to the mills.

May Get Less In Future

"It looks as though there would be no increase in the allotment of material for this country. In fact, it really looks as though there might be a considerable cut in the volume of material for the Dominion. The sheet situation is causing not a little worry to a good many of the Canadian houses. There is a queer situation just at the moment. The big mills that can convert from sheets to plate have been ordered to do so by degrees. The first move was that 25 per cent. less billets should go to the sheet mills, that material being turned to the plate rollers. Now there has been notice sent out, and it will be operative in a few days from this, that another twenty-five per cent. shall be taken for the plate producers. The little mill that cannot turn over to anything but the rolling of sheets is left more alone, and to-day there is more money in the turning out of sheets than in the making of plate. That condition is not likely to run much longer, and it is these purely sheet mills that have been looking largely after the Canadian trade in that particular line.

The Vulture Is There

"There was one mill man in Pittsburgh," continued Mr. Near, "who gave me a pretty good outline of the demand for steel. He stated that there were jobbers hanging around there all the time in the hope that there would be a little over on the order of some firm that they might have a chance to buy. They also have the hope that there may be some half-spoiled material coming from the rollers that will not do for contract work. They hang around here for these pickings like a lot of vultures most of the time. Anything that is steel—that is about the extent of their specifications. He laughingly compared this to the specifications that the Canadians brought down, expecting to get them attended to at the mills at once. The Emergency Fleet board has a faculty of sending out specifications for a lot of work that has been very carefully worked out in advance and which requires an immense amount of care in the mills. There is generally a grand scramble to see if this particular order can't be loaded on to some other mill.

Have No Ruling

"As a matter of fact," concluded Mr. Near, "the Canadian warehouses have no ruling or standing at Washington. We are now, and have been for some time practically at the option of the mills as to whether we keep going or run out of stock. The trade is gradually working into a narrower margin and I can't see anything that would make me believe that the situation is likely to be relieved in the near future."

CEMENT CO. HAS A BIG MUNITIONS ORDER

And Work Will Be Started Very Shortly on Building of the Plant

The Canada Cement Co., Montreal, have recently received a munitions contract from the American Government, the total value of which will approximate $10,000,000. A new plant will be erected to cost about $1,000,000, the outlay to be guaranteed by the U. S. Government. The work involved will include the furnace production of the steel, the making of the billets, the forging and machining of the shells. Operations on the new plant addition will commence almost immediately.

GEN. PERSHING KEEPS U.S. DIZZY CALLING FOR MORE SUPPLIES

Special to CANADIAN MACHINERY.

PITTSBURGH, Pa., Sept. 19.—General Pershing wants at least 100,000 3-inch shells a day. As this is entirely apart from his requirements in other sized shells as well as such shells as the United States might be able to make for Britain and France a very large proposition is presented and the Ordnance Department is pushing hard on the semisteel shell program. Last week a meeting was held in the Pittsburgh Chamber of Commerce auditorium, attended by 300 representatives of foundry and machine shops in western Pennsylvania, eastern Ohio, West Virginia and Western Maryland. Representatives of the Ordnance Department stated that they wanted 33,000,000 semisteel shells during the next ten months and insisted that more than half of the total ought to come from this district. It was urged that even those who could perform only part of the work on a shell participate, machine shops without foundries attached being expected to take hold as well as foundries. The semisteel shell program includes as minimum requirements, in addition to orders placed, the following: 1,500 daily 12-inch high explosive; 5,000 daily 155 mm. shrapnel; 35,000 daily 155 mm. high explosive; 80,000 daily 75 mm. high explosive. Prior to last week's meeting 31 representative foundrymen had visited the American Radiator Company's plant at Buffalo, where there is now a daily output of 100 6-inch shells, with prospects of largely increased output in the near future. Representatives of the Ordnance Department stated at the meeting that the specifications would be made as simple as possible and that every effort would be made to assist manufacturers taking up this line of work.

Shell Steel and Rails

The demand for such large numbers of semisteel shells does not mean that there is any relaxation in the pressure for regular steel shells but of course, it shows that the total shell requirements have become so large that it is out of the question to meet it with steel shells alone. Rails and shell steel have come into sharp competition, because there has been a considerable production of shell rounds at rail mills and rail requirements having lately increased very sharply it is impossible to increase shell steel production at such plants and decreases might even be necessary. The recent decision to remodel two wire plants, Donora and Woodlawn, to produce shell rounds instead of wire rods, will eventually help. In addition to the 150,000 tons of rails ordered a few weeks ago for the A. E. F. it is understood there are large additional requirements, occasioned by constant advances in the battle line. Possibly the Franco-American drive initiated last week, whereby the St. Mihiel salient was promptly wiped out, has something to do with this, as large guns will have to be brought forward if the Metz fortifications are to be attacked, and the gun movement would require large quantities of rails. It has been known in the steel trade in Pittsburgh for months that the French have had large guns ready for a long time past against the time when activities should be initiated at this point. The steel trade, it may be mentioned, is naturally particularly interested in this phase of the military operations, seeing that its objective would be the control of the Minette ore district from which Germany secures nearly its entire supply of steel.

Tin Gets Another Cut

As a means of saving steel the War Industries Board has ordered, for the fourth quarter of the year, a 30 per cent. reduction in the supply of sheet bars to the tin plate mills, and it chances that the major portion, if not all, of the curtailment will be at the Edgar Thomson steel plant of the Carnegie Steel Company, which by reducing its output of sheet bars will be able to make correspondingly more rails. Last May a precise allotment of sheet bars to each tin plate plant was ordered, a definite weekly tonnage per mill, whereby there has been an absolutely full supply of steel for the tin plate mills, to insure a full supply of cans for the perishable food crops. This now being taken care of, it is feasible to reduce the output of tin plate. After January 1 the allotment will no doubt have to be increased. The saving in steel in the three months' tin plate curtailment will be between 125,000 and 150,000 tons. As a measure of comparison, it may be mentioned that one mile of track in 85-pound rails involves about the same amount of raw steel as 1,000,000 two-pound tin cans.

Apart from the rail requirements for the overseas military operations, Director General of Railroads McAdoo wants 60,000 tons of rails a week for replacement on domestic roads and for building new track. In the steel trade it is considered impossible to meet such a demand, but in the past few weeks the deliveries have at any rate been much heavier than formerly. Mr. McAdoo was in Pittsburgh last week in his inspection of railroad conditions and he summoned to meet him here A. W. Calloway, manager of bituminous coal production for the Fuel Administration and J. Leonard Replogle, Director of Steel Supply for the War Industries Board. The motive was obvious. The Fuel Administration wants more coal to be produced and calls for more transportation facilities, while the Railroad Administration in turn wants more steel from the War Industries Board, hence Mr. McAdoo brings Mr. Calloway and Mr. Replogle together.

Other Steel Restrictions

The only precise fresh restriction in

the use of raw steel in finishing departments is that mentioned above in the case of tin plate. Other restrictions are being considered, relating to the use of steel in merchant bar mills, pipe mills and wire mills. In the past few weeks these three classes of mills have been operating at an average rate of not more than 60 per cent. of capacity. Possibly decision in these matters will be aided by the inventory now being made of stocks of steel in the country, as a result of a questionnaire recently sent out by the Census Bureau in behalf of the War Industries Board, whereby steel producers, finishing mills, jobbers and manufacturing consumers are required to report their stocks in detail. Some stocks may be found that can be utilized for distribution to plants engaged in war work.

Production

The monthly report of the American Iron and Steel Institute indicates that steel ingots were produced in August at the rate of about 40,300,000 gross tons a year, against rates of 42,250,000 tons in July and 43,500,000 tons in June. The June rate was the best on record, barring only the rate last October. The July and August decrease reflects summer weather, particularly the record hot weather that prevailed in the central west during the first 12 days of August. On the whole, the midsummer drop in production was less than usually occurs, and there is good reason for expecting the June rate, or a higher rate, to be attained this month or next. Already there are reports of individual mills doing much better thus far this month than in the corresponding period of August. Some statistics gathered last May indicated an output of finished rolled steel equal to 78 per cent. of the production of ingots. Prior to the war the proportion was almost constant at about 76 per cent., the loss being in roll scale, scrap, etc., practically all of which is recovered. When shell steel manufacture for the Allies was undertaken the proportion dropped a trifle, on account of the heavy discards, but now it appears that some relaxation in the specifications, more skill on the part of the mills, and the employment of discard steel for various war uses are having their effect in pulling up the percentage. Using this factor, the ingot production in July and August would point to the production in the two months of about 6.000.000 net tons of finished rolled steel. This is to be considered in connection with the War Industries Board's recently increased estimate of 23,000,000 net tons of steel being required in the half year, with its very conservative estimate that only 17,000,000 tons production could be counted upon. If the two midsummer months produce 6,000,000 tons the half year ought to show at least 19.000,000 tons. This would still be 4.000,000 tons short of the estimate and the less important of the commercial uses, recognized as helpful in winning the war, cannot be allowed much steel.

U.S. MAKES DRASTIC MOVE RE STRIKERS

Will Insist Upon the Acceptance of the Work or Fight Rule in Every Case

Special to CANADIAN MACHINERY.

NEW YORK, Sept. 19th.—War industries in various parts of the country are constantly buying machinery. The greatest activity is in the Central West. The barred industrial zone has shifted the heaviest buying from the Eastern section. The Government is still buying tools and cranes directly, but the largest orders are being placed by private makers of guns and ammunition. Shipbuilders and manufacturers of railroad equipment are placing additional contracts and some large orders are still pending.

Labor strikes affecting war industries have finally brought drastic action by the President. The Federal policy of industrial war-labor control was determined upon as a result of the refusal of striking machinists at Bridgeport, Conn., to accept an arbitral decision of the War Labor Board. The new policy applies to both employers and to employees and may be epitomized as follows: First, the Federal Government will take over and operate the plants of employers who decline to abide by decisions of the War Labor Board. Second, striking employees who ignore or temporize with these decisions must return to work or be barred from employment in any war industry in the community in which the strike occurs for a period of one year and face rejection of any claim for exemption from the draft law based on usefulness in war production.

One Result

The plant of the Smith & Wesson Co., Springfield, Mass., which has been making pistols for the Government, has been commandeered by the War Department as a result of the Government's industrial policy above outlined; also, many strikers at Bridgeport have returned to work while other machinists unwilling to resume their old places are seeking employment at war industrial plants elsewhere.

In the Central West, especially at Chicago, labor conditions, which were going from bad to worse, are expected to be improved immediately by the President's action. In several cases, adjustments of difficulties have come before the War Labor Board. If decisions of the Board are rejected, the "work or fight" mandate will be put into effect.

The American Brake Shoe and Foundry Co. has come into the market for 150 tools to be installed in its Erie, Pa., plant for the manufacture of guns; the list includes 100 plain and vertical milling machines and 50 8-inch, 20-inch and 24-inch lathes. The Government has

THERE'S A BIG GAP UNFILLED IN THE AMERICAN SCRAP TRADE

THERE seems to be no let-up in the demand at U.S. points for scrap metals. Canadian yards on the other hand are well filled, and consumers here are being much better supplied with this material than those who are depending on U.S. markets. The embargo is still on in this country and Canadian yards are not allowed to ship certain grades to U.S. points. The situation in U.S. at the leading points is described in the following despatches—

Chicago.—A very large demand for heavy steel scrap is being received from Eastern points, but permits are not being issued for this material to leave this district.

New York.—Dealers here report that there is a very brisk demand practically for everything they have to sell, and on account of this, and also on account of the fact that very little material is coming out, prices remain firm at the Government maximum.

Pittsburgh.—There is no question but that users would absorb a very large amount of scrap over and above that which they are receiving were they able to secure it. The open hearth furnaces have benefitted to a very large extent by the embargo which has prohibited turnings from going to the blast furnaces.

Cleveland.—There is a good demand for heavy melting steel, turnings and low phos. are the scrap and iron and steel grades that are most wanted. There are numerous complaints being made over the car service, and deliveries on orders are rather indifferent on this account.

Cincinnati.—The price being paid now for labor in the scrap yards very seldom gets a chance to go below the 40 cents an hour mark. Some of the dealers here are inclined to be somewhat pessimistic about the future because the small dealers are not sending in anything like the amount of stuff that they have done in the past.

Philadelphia.—There has been some controversy going on here in regard to the standing of the scrap industry under the new draft regulations. Dealers however, are inclined to call attention to the ruling of General Crowder, in which he recognises the fact that the scrap industry was essential, and on this ground it is quite proper for dealers to claim exemption for any men they may have working in their yards.

Buffalo.—There is small chance of any of the dealers here accumulating any reserve stock against the winter months, when it will not be coming in as freely as it is now. All the tonnages that show up here are immediately absorbed by the trade.

Complaint is made that the high cost of labor leaves little incentive toward trading on the ground that since the Government prices were fixed there is little opportunity for the trade to make any money. There is a very keen demand for heavy melting steel, and in fact for any other heavy grades.

placed additional orders for guns and shells, and as a result several new inquiries for round lots of machine tools have been put out, including one for 50 tools and another for 25 machines for making guns and gun parts. Non-essential industries that are now preparing to manufacture airplanes, escort wagons and other war munitions have been actively buying small lots of wood-working machines in the Cleveland, Ohio, district. The Winchester Repeating Arms Co., New Haven, in preparing to double its output of ammunition, will purchase $500,000 worth of shop equipment, but orders will not be placed until sanctioned by the Government. The large purchases contemplated by the Baldwin Locomotive Works are still pending. The Baltimore Car & Foundry Co., a subsidiary of the Standard Steel Car Co.. will expend one million dollars for building and equipping a fabricating shop which will be utilized in shipbuilding work.

The Navy Department will make purchases of a number of machines for the large structural shop which will be built at the Mare Island Navy Yard. Bids have been taken on 6,200 tons of steel for this plant and it is expected that an award soon will be made to a. Pacific Coast builder. The Department has taken over the Harrison, New Jersey, plant of J. J. Spurr & Sons, which will be equipped for assembling and installing machinery in submarine chasers and other boats now being constructed at the Brooklyn Navy Yard.

The Ordnance Department has placed a number of orders with various manufacturers for 80-inch lathes and preparations are being made for the purchase of 102-inch lathes to be used in the manufacture of guns at Government arsenals.

IRON TRADE IS LOOKING TO LAST QUARTER FOR MORE MONEY

THE iron trade is, of course, greatly concerned over the meetings that are being held now looking forward to the fixing of prices for the last quarter of 1918. The producers of pig iron are pressing their claims for consideration, and they will certainly draw attention to the widening gap in production costs in various districts due to higher ore, freight charges, and other considerations. The demands at all points for steel making iron are referred to as being intense, munition production calling for a greater output than as heretofore seen possible.

Reports from the leading centres on the American continent are as follows—

PHILADELPHIA—The dealers here are showing considerable interest in the forthcoming action by the government on prices. Producers from here are in conference at New York. There is a feeling that the War Industry Board may not be inclined to allow any increases in price for this year, but it is certain that the producers will press the point, and make a strong try for prices on a higher level.

NEW YORK—The 1919 situation remains rather uncertain here, and it is worthy of notice that the present system of allocation is causing some rather peculiar situations, as in some cases producers are being given tonnages of iron for consumers with whom they had previously broken off trade relations, and whom under ordinary circumstances they would have no intention of supplying. Under present conditions though they have no choice in the matter. On the other hand they are many producers who are not able to take care of those firms who have been good customers of theirs in the past. Speaking of prices some of the southern furnaces have experienced the 250% increase in the freight costs on raw materials, while labor and other costs have risen materially, and it is certain that these interests will press for higher prices.

PITTSBURGH—There is no question but that inquiries here are numerous enough, but very few contracts are entered into, in the fear that they may in some way interfere with the Government distribution of the supply of iron. Production is coming along nicely, and there might be quite a large increase were it not for the fact that the coke continues to be of a poor quality.

BUFFALO—There does not appear to be as far as can be ascertained any 1919 contracting going on now. In fact, the trade seems to be waiting until the new classification of industries is given out.

CHICAGO—It appears that there is going to be some trouble in store for those melters who have not made out the reports covering their receipts and consumption of iron during the past month, and it may be that they will get no supplies whatever. Strict instructions are issued to furnaces and delegations to regard these industries as unessentials. They automatically enter that class when they neglect to send in their reports.

CINCINNATI—The great stove trade in this city and district is in a peculiar situation just now. So far the stove foundries have been able to operate, but if latest reports are correct they are going to have a hard time of it during the first half of 1919 in which they will have little or no iron at all.

ST. LOUIS—To get some conception of the position of some of the non-war plants, in regard to the supply of iron, it may be mentioned that some of the largest of them are now announcing that they are now in the market to take contracts from any plants that have Government work. For instance the Buck's Stove and Range Co., one of the largest in the U.S., are advertising in the daily papers, soliciting work from other manufacturers in the lines in which they specialize. They state that the curtailments in the matter of fuel, iron and steel have cut down their output to a very small amount.

SYSTEM OF CONTROL IN ENGLAND NOT UNLIKE THAT OF THE STATES

THE system of controlling the iron and steel industries in this country is well known, but not so much has been said about conditions in England. The following factshave been forwarded to CANADIAN MACHINERY in this connection:—

"In order to ensure that supplies of steel as far as possible be forthcoming for the most urgent work, a system of control of rollings has been instituted. The country has been divided up into six areas, each of which has been placed in charge of a Steel Superintendent, who represents the Admiralty and the Ministry of Munitions. One of his chief functions is to advise and assist firms within his area to obtain the supplies of steel needed by them for authorized purposes.

"The rolling programmes at the principal works in the areas are arranged by the Steel Superintendent in consultation with expert Area Committees, composed of representatives of the principal mills. It follows that the Steel Superintendent, who is in constant communication with his colleagues in the other areas, is in a position to give authoritative information in regard to the prospects of obtaining material. To facilitate the regular and frequent rollings of sections, a list of standardised sections has been drawn up and published for information; and if firms confine their requirements for sections to this list there should rarely be any delay in obtaining supplies necessary to enable work to proceed promptly. The needs of the various services and the country generally have been carefully estimated, and the available supplies have been allocated pro rata. In order to ensure that the supplies available do, in fact, go to the destinations allotted, statistical returns are regularly obtained, which give particulars of all manufacturers' deliveries to their various customers. The system of what is known as "Prefix Lettering" for orders has been instituted. These prefix letters indicate the services for which the steel ordered thereunder is to be used, and it has been laid down that no order may be entered or executed unless it bears its appropriate prefix lettering followed by the Admiralty or Ministry of Munitions priority or permit reference, or Government Contract re-

The Making of Milling Machine Dog and Driver

Up-to-date Process in Which a Large Number of Operations Are Involved—Good Methods Used in Locating the Forging

By ROBERT MAWSON, New York

IN this article is described the various operations and tools used when manufacturing a milling machine dog. The practice is largely followed of first machining some important hole and afterwards using this as a locating medium for all subsequent operations.

A quick acting type of jig which is operated with a crank is worth noting, as it is giving good satisfaction in service.

Another milling fixture which utilizes a pin locating into notches on the tool and a previous drilled hole is another interesting tool.

This article deals with the various operations in making what is known as the Kempsmith style.

One of these is shown in the illustration Fig. 1.

By the use of this dog on the milling machine greater accuracy is obtained for such work as gear cutting, machining flutes on reamers, etc.

It will be seen that the tool consists of a driver A and driver arm B.

A ball C is attached to the arm which is a good sliding fit in a groove on the tail of the driver. The action of this ball sliding in the tail between the groove jaws D acts as a universal ball and socket joint.

This removes any tendency to cramp or spring the work since the movable parts of the jaw provide contact without torsional strain.

FIG. 1—A COMPLETE MACHINE DOG.
FIG. 3—DRILLING FOR SET SCREWS.

FIG. 2—BORING AND REAMING DRIVER.
FIG. 4—TAPPING FOR SCREW HOLES.

Boring and Reaming Driver

The first operation on the driver is boring and reaming the groove in the jaws. This operation is shown in Fig. 2.

The forging is placed in the jig with the cover swung back and located against the screw A, being forced against it with the set screw B.

The cover is then swung into position and the screw C tightened onto the forging which not only forces it back but holds it securely in the jig.

A 1 7/64 in. hole is then drilled in the pieces and after the slip bushing has slid along the table so as to bring the hole to be tapped in line with the tap.

It will be seen that the fixture is made with a block A which is placed in such a position that when the forging rests upon it the holes to be tapped are in a horizontal position.

The holding of the piece is a simple operation.

The forging being slid in from the end of the fixture, the handle B forces the block C (by means of the travel of the screw) against the part, thus holding it securely.

forces it down against the lower wall D of the jig.

A hole is then drilled and tapped and the upper part counterbored to suit the binding screw.

The jig is provided with slip bushings so that the various operations may be performed before removing the piece from the jig.

The next operation is drilling the hole for the bottom of the slat and the jig used is shown in Fig. 6.

The forging is again located from the reamed hole in the jaws by means of the

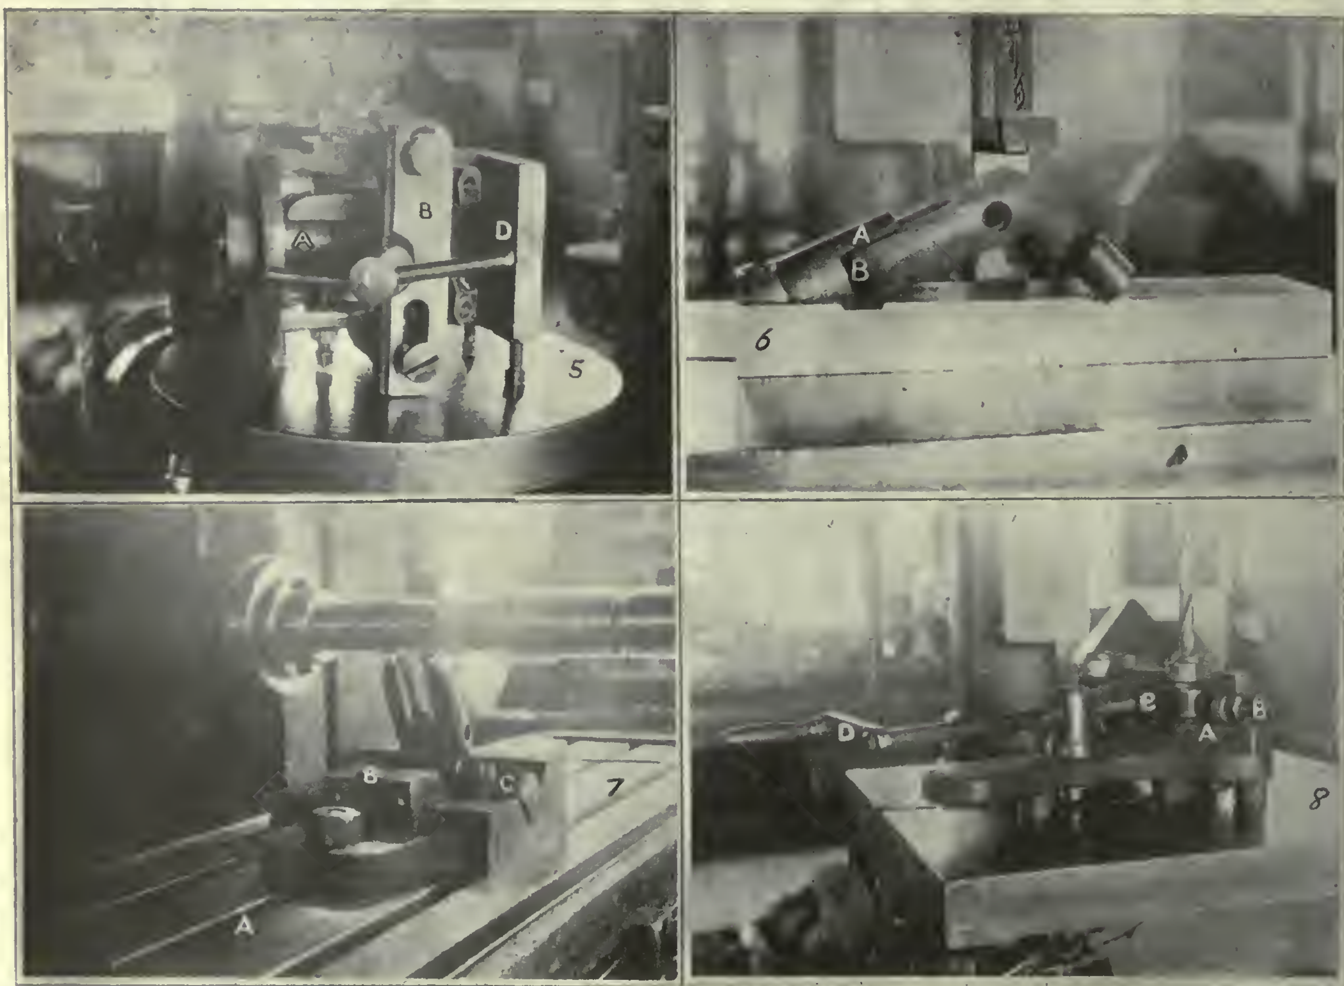

FIG. 5—MACHINING FOR BINDING SCREW.
FIG. 7—SLOTTING THE DRIVER.

FIG. 6—DRILLING HOLE FOR SLOT.
FIG. 8—DRILLING THE CAP.

been changed to suit, the hole is reamed to 1⅛ in., this operation being shown in the illustration. The next operation is milling the vee and facing the joint surface, the forging being held in a vise and a set up of standard cutters being used for the machining operation.

In Fig. 3 is shown the jig used when drilling the set screw holes.

The forging is located by a raised vee block which fits into the surface already machined, the screw A operated by the handle forces back the block B against the forging and holds it securely on the jig. Two holes are then drilled, the tool being guided by bushings as shown.

The holes are next tapped on the fixture shown in Fig. 4.

This tool merely holds the piece and is

Machining for the Binding Screw

The next operation is machining for the binding screw for the jaws.

The purpose of the screw is to adjust the jaws so that the ball will be a good sliding fit, with no play or binding action.

The jig used when drilling for the screw is shown in Fig 5.

The forging is located by the plug A which fits into the reamed hole of the jaws. To place the piece in the jig the strap B is swung back. thus enabling the forging to be dropped into the tool and the plug being slid into the reamed hole of the jaws from the end of the jig accurately locates the part.

The cover is then swung back and the screw C being tightened against the piece

plug A being pushed back against a shoulder at B.

A 7/32 in. hole is then drilled, the tool being guided by means of the bushing in the usual manner.

Slotting the Driver

The next operation is slotting the driver and the method used is shown in Fig. 7.

A rather interesting method of locating the forging is followed in this operation.

The milling cutter or saw which is 3/16 in. thick is set up and the table moved until the cutter is exactly central with the slot A.

The fixture is fastened down to the machine, being located by means of

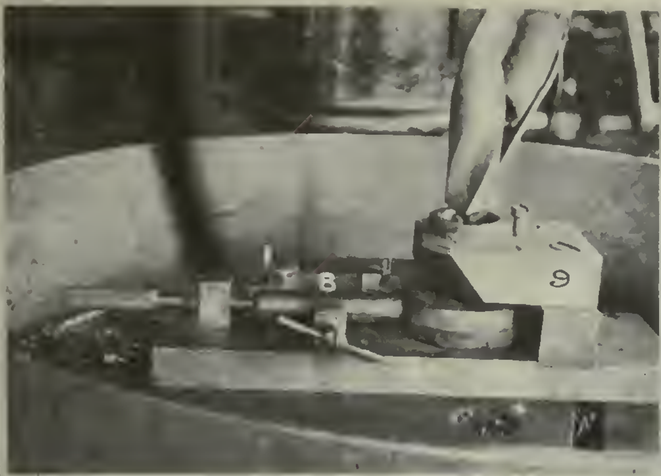

FIG. 11—DRILLING CENTRE FOR SHANK.

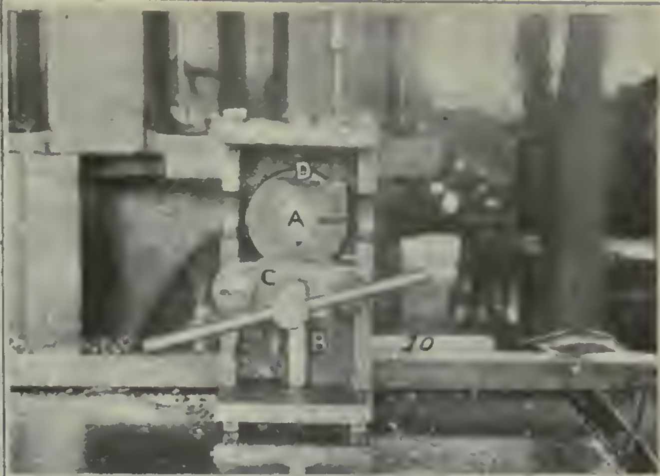

FIG. 12—MILLING SLOTS.

tongues in the usual manner.

A 7/32 in. wire is then placed through the hole of one of the forgings—this it will be remembered is the size of the hole drilled in the previous operation—and the wire is placed in vee B, one in front and the other at the rear of the fixture.

The forging is then fastened down with two straps as C and the wire removed.

The revolving saw is then passed through the forging and the slot is exactly in line with the previously drilled hole. This method is simple yet accurate in results and after the fixture is once set produces duplicate parts. When machining the cap for the driver the first operation is milling the vee and facing and is performed in a manner similar to that described for the driver. The next operation is drilling and counterboring and the jig used is shown in Fig. 8. The forging is placed on two blocks A one on each side so that the vee of the forging does not foul with the jig.

The forging is located against a set screw at the rear of the jig, being forced against it with the set screw B.

The block C being screwed against the forging with the handle D forces back the piece and holds it securely in the jig.

Two holes are then drilled, the body size of the set screws.

These holes are then spot faced to suit the head of the set screws.

Drilling Driver Arm

The first operation when machining the driver arm is drilling and reaming the centre hole.

For this operation the forging is placed in the jig Fig. 9, being located by the blocks A and B, being forced against them with the screws shown.

The large hole is then drilled, afterwards being reamed to size.

In Fig. 10 is shown the jig used for the next operation which is drilling for the set screw.

The forging is placed on the pin A and located in a vee block B with the latch C swung back.

After the forging is in position the latch is swung over and the pin headed set screw being tightened against the piece holds it in position.

The set screw hole is then drilled, redrilled for body size, counterbored and the lower part of the hole tapped, slip bushings being provided for the various sub-operations.

The forging is also drilled and countersunk at D for a centre, the jig being provided with a bushing for the purpose.

The jig is then reversed as shown in Fig. 11 and the end of the forging drilled, tapped and countersunk for turning for a centre which is used in the next operation.

It will be noticed that a bushing A is provided so that the centre will be in the correct location in reference to the shank.

The shank of the forging is next turned to 0.5725 in. diameter, the operation being a simple lathe job. A keyway is next cut in the large hole and needs no explanation. The forging is next slotted for the binding screw and the fixture used is shown in Fig. 12.

It will be seen that this tool is designed to hold 13 forgings at once and they are located by means of the pin A which is made a sliding fit in the centre reamed hole.

The shanks of the forgings rest on the bar B as illustrated.

The screw C is then tightened against the nest of forgings and forcing them back against the rear wall of the fixture holds them securely.

The fixture is located and held to the milling machine in the usual manner.

A 5/32 in. slot is then milled in the forgings as illustrated.

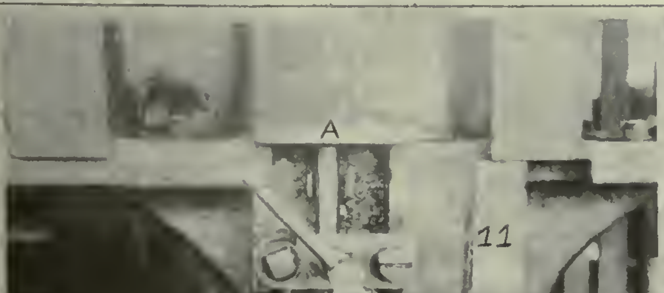

FIG. 9—DRILLING LARGE HOLE.

FIG. 10—DRILLING SET SCREW.

The sides of the forging are next ground so that they are square with the centre hole. The forgings of both elements are polished all over at this stage until a smooth appearance is obtained.

Heat Treating the Forging

The forgings, both driver and driver arm, are then taken to the heat treating department and are first hardened at 1650 deg. Fahr. and then quenched in oil. They are then given their second hardening, being heated to approximately 1,350 deg. Fahr., dipped in a cyanide bath, then given a quick quench in water and finally cooled off in oil. This second hardening produces the mottled effect on the parts.

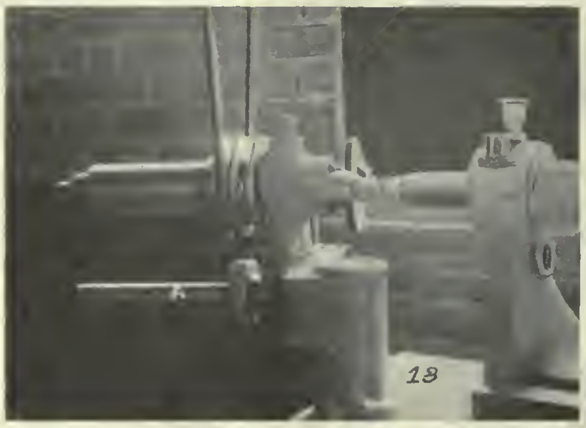

FIG. 13

The shanks of the driver arm are then ground to 0.5625 in. as the next operation. The operations when making the ball for the shank are as follows:—

Drill, ream, counterbore, form and cut off in screw machine. The ball is next hardened for the next operation.

The inside hole is then ground to size as a following operation.

The special machine used when grinding the outside of the ball is shown in Fig. 13.

The piece is placed on a pin which fits snugly the reamed hole. The grinding wheel is then oscillated around the revolving ball by means of the handle A.

The method of driving the grinding wheel can be observed by referring to the illustration.

The table carrying the ball is gradually fed against the rotating grinding wheel which is oscillated until the ball is perfect in contour and exactly 1⅛ in. in diameter. The ball is then attached to the shank of the driver arm and lapped into the driver jaws so that it will work smoothly at every point.

The various parts are now ready to be assembled—driver and its cap with driver arm and ball complete with screw when they are placed into stock ready for service.

DRY AND WET COAL

The effect upon the efficiency of a boiler when using wet and dry coal has not been definitely known, according to J. J. Light, instructor in mechanical engineering, in Bulletin No. 22 of the Engineering Experiment Station of the Pennsylvania State College. Among coal users, especially those operating house-heating boilers, there is a wide difference of opinion as to the relative merits of the practice of wetting the coal before firing. The object of a series of 10 tests tabulated was to show the efficiency of a house-heating plant when fired with coal that has been made wet, and with coal as usually found in cellars of residences, which can be considered as practically dry.

Since two series of tests were run under the same conditions except for moisture of the coal, it is possible to obtain information as to the benefits derived in house heating by firing either dry or wet coal. The conclusion is that the common inference that an addition of water to the coal as fired is beneficial to the operation of the furnace seems false.

The tests from which the results were obtained were in charge of an experienced fireman, who had very strong convictions, from his practical experience, that moistening the coal was a decided commercial advantage in the operation of boiler plants, which fact would in all probability produce an error in favor of wet coal provided any error was introduced.

The item, equivalent evaporation from and at 212 deg. Fahr. per pound of combustible, and the item, efficiency of the furnace, are two factors which would appear to decide the relative merits of the wet and dry coal. It developed throughout the tests that one pound of combustible evaporates more when the coal is fired dry or as is ordinarily found in cellars of residences than when it is purposely moistened. The efficiency of the furnace throughout the tests showed that wet coal tends to decrease rather than increase operating economy.

From a theoretical point of view the addition of water to the coal is a decided loss and would probably be equal to the heat required to evaporate the water added, from the room temperature into steam at a temperature corresponding to the flue gas under the pressure as maintained in the flue. It is the opinion of those who are believers in moistening the coal that the addition of water aids in the complete combustion of the volatile hydrocarbons. This fact probably cannot be disputed, but the tests showed that the gain due to complete combustion is less than the heat carried away by the water. The small differences in efficiencies would, however, hardly be noticeable to most people, and it is quite natural to think that wet coal would give the best results for the reason that coal being wet when placed upon the fire produces slower combustion. This would give better conditions for the combustion of the volatile and other hydrocarbons, but the tests seem to indicate as well as theory that the heat required to burn the wet coal is greater than the heat lost by firing the dry coal.

METHOD FOR THE COMBUSTION OF BROWN COAL

By M. M.

Mr. E. H. Miller has introduced a process for the economical combustion of inferior qualities of coal in boiler furnaces, which gives a greater thermal return than when such coals are burned in air in the usual way. The principle of the process is to apply the conditions that exist in the water gas producer to the boiler furnace, and use exhaust steam for gas production. To accomplish this the producer forms part of the boiler setting, and is placed immediately under the present fire grate area. The ash pit and grate are dispensed with, and in their place is a chamber which is used for the combustion of the gas. By means of this chamber, which is situated immediately under the tubes in the tubular boiler, complete combustion of the coal is assured. The use of exhaust steam obtained from auxiliaries for gas generation permits of the latent heat of the steam being made available which represents nearly five-sixths of the original heat used to form the steam. The water gas, when generated, is at high temperature, and is mixed with air pre-heated by passing through the flues, and ignited. As the combustion takes place almost immediately, after the gas is generated, conditions are such that permit of obtaining a high percentage of the thermal contents of the fuel as effective heat for evaporation.

Experiments have been made using Morwell brown coal, containing over 20 per cent of water, and excellent results have been obtained. Complete control of the combustion is possible, the combustion being absolutely smoke-less. Morwell brown coal lends itself particularly to the preparation of water gas, the high percentage of the water in the coal being in no way detrimental to the formation of the gas. Such coal, when burnt in chain grate or under feed stokers, usually begins to burn when about to be discharged to the ashpit, the high percentage of water having lowered the temperature of the combustion zone long before combustion is complete. The advantage of generating water gas instead of producer gas (carbon monoxide) is that about twice the quantity of coal can be gasified on the same grate area when making water gas than when making producer gas; also advantage can be of the latent heat exhaust steam.

Tantiron; An Acid Resisting Ferro-Silicon Alloy

Acid-resisting Irons of Great Use in Industry—Replace Far More Expensive Metals and Give Equal or Better Service

THE manufacturing chemist and metallurgist are greatly restricted by the limitations of applicability of their apparatus. In many processes, the difficulty is not so much to obtain the raw materials as to find furnaces, containers, pipes, &c., that will bear the chemical and physical stress of the reactions, and to avoid the contamination of the products by the substances with which the reactions bring them into contact. For these reasons many a promising process never gets beyond the laboratory stage; hence, also the cry for substitutes of rare, expensive materials, as well as the natural distrust of them. The enhanced activity of certain chemical industries has much increased the demand for refractory materials and acid-resisting alloys. Experiments with acid-resisting iron alloys are not new, of course. Wollaston made a silicon-iron, and he may not have been the first. Engineers and electricians found silicon-iron very useful for special purposes, and many attempts were made to construct chemical plant of silicon-iron and other iron alloys. Tungsten, chromium and nickel were tried. But foundrymen seemed to be unable to make vessels even of moderate dimensions of such materials, and it was not till 1912 that an acid-resisting iron alloy of sufficient uniformity and strength for the engineer to deal with was put on the market, states "Engineering."

It was the tantiron of Mr. R. N. Lennox, made by the Lennox Foundry Company, of Glenville Grove, New Cross, S. E. Since then silicon-iron and other noncorrosive iron alloys have been brought out by several firms. Both the "duriron" of the Duriron Castings Company, of Drayton, Ohio, and the "ironac," of the

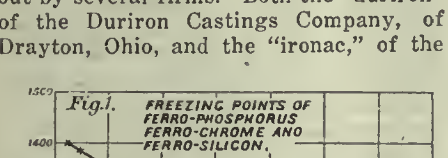

FIG. 1

Houghton Company, of London, are silicon-irons, like the métillures of A. Jouve, one of the first in this field, and the Italian eleanites, which contain about 2 per cent. of nickel. The American rights for tantiron were, in 1913, taken over by the Bethlehem Foundry and Machine Company, Pennsylvania. "Ferrochrome" is supplied by the Electrometallurgical Company of Niagara Falls; the "feralun" is likewise an American product,

FIG. 2

and German activity in the field will not have ceased during the war; in addition to "neutraleisen" there are ferrochromes and ferro borons.

That Mr. Robert N. Lennox should have taken up the manufacture of apparatus for the concentration of strong acids was only natural. His father had made sulphuric acid in Glasgow in the days when heavy investments in platinum plant were indispensable for that purpose. When Mr. Lennox started a foundry on his own account, he had for a good many years conducted experimental engineering works of his own, and had, as assistant in the Royal Institution for nearly 25 years, taken his share in Sir James Dewar's low-temperature and high-pressure researches and in the manifold other investigations which are being carried on in the Royal Institution. Extensive well-equipped laboratories are a noteworthy feature of his works.

Properties

Tantiron—a fancy name—is a silicon-iron, containing about 15 per cent. of silicon. In appearance it is a silvery-white close-grained cast-iron, and has the general properties of a machinable cast-iron. One special brand of tantiron is very hard, and not machinable; another quality resists hydrochloric acid which the others do not. It melts at about 1,200 deg. C., can be cast, ground with carborundum, cut with the saw, drilled, screw-cut and tapped, &c. So far as chemical and mechanical corrosion is concerned, it is a superior iron and is used for cast vessels or in the shape of linings for those of steel or iron. It does not rust, except at the skin, and the rust is removed by pickling in diluted sulphuric acid or by grinding. The tantiron itself is not—or practically not—attacked by sulphuric, nitric, or acetic acids, concentrated or diluted, boiling or cold, and indeed not by most chemicals. One kind already mentioned—a more recent invention—also resists hydrochloric acid equally well. Carbonic acid attacks it slightly, but the corrosion is only about one-thousandth that of cast-iron. Alkalis corrode it about as much as they do cast-iron; chlorates and perchlorates do not corrode it, and it will resist chlorine gas up to a temperature of 105 deg. C. But sulphur dioxide corrodes tantiron badly. In view of this latter fact, the suitability of tantiron pans and basins for the concentration of sulphuric acid is rather surprising Large pans have been in use, however, we are informed, since 1912, and some 25,000 basins are actually in use in sulphuric-acid works. There is some slight corrosion, of course, and there are breakages, partly due to the material, partly to improper treatment by unskilled labour, which causes many small and large accidents in these days of rapid plant erection and high-pressure activity. The maintenance cost of pans and basins is about 2½d. or 3d. per ton of acid concentrated. After boiling 100 grams of the alloy for 17 hours, 10 per cent. sulphuric acid was found to have dissolved 0.13 gram of tantiron, 25 per cent. nitric acid, 0.25 gram, and 30 per cent. hydrochloric acid, .16 gram.

Limitations

The terms "non-corrodible and acid-resisting iron," are misleading, as all such general terms are. Every chemist knows that he must not allow metals to glow in his platinum crucible, as they would form fusible platinum alloys, and that caustic alkalis and certain alkali salts, and even the sooty flame of the gas burner, will ruin his crucible. Tantiron also has its peculiar weaknesses. It resists hot sulphuric acid much better than cold acid, and many instances of attack are so far inexplicable. In one case, a tantiron tower containing vapours from boiling sulphuric acid showed defects in the top sections, without any attacks on the bottom sections. The top sections were replaced several times; the bottom sections, which had

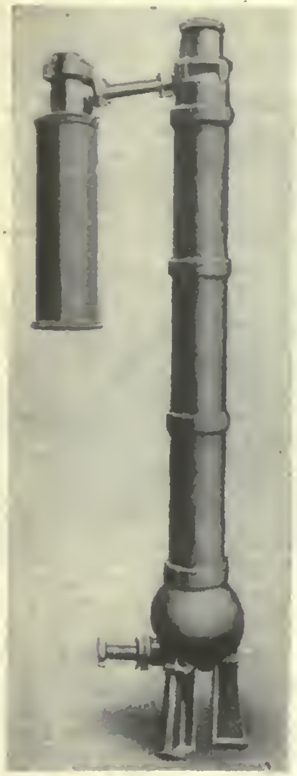

FIG. 3—DENITRATING TOWER

been in use for eighteen months, were taken out and inserted in the top, when they were attacked within a fortnight; yet temperature determinations at different points of the tower never showed differences exceeding 5 deg. C. In other cases, sulphuric acid, on being carefully freed from arsenic by sulphuretted hydrogen, attacked the tantiron nearly three times as quickly as the original acid. But the amount of attack is, of course, exceedingly small. A tantiron vessel weighing 4,950 grams, had 600 tons of sulphuric acid passed through it during concentration with a total loss of weight of 12 gram. The attack is mainly on the surface of the skin, which should, therefore, be removed when corrosion tests are conducted.

Though the iron carbide seems chiefly to be attacked, the corrosion is, apparently, uniform; under the microscope, acid-corroded tantiron keeps its smooth surface, while cast-iron shows irregular corrosion. Mr. Lennox prefers to have no carbon in the iron at all. His raw materials are cast-iron, scrap, and old tantiron, and further ferro-silicon. The latter is obtained with about 12 per cent. silicon from Middlesbrough, and in a 50 per cent. grade from Norway. The average composition of tantiron is in per cent.: silicon, 14 per cent. or 15 per cent.; total, carbon, from 0.20 per cent. to 0.60 per cent.; manganese, 0.25 per cent. to 0.35 per cent.; phosphorus, 0.16 per cent. to 0.20 per cent.; sulphur, under 0.05 per cent. The three kinds mentioned, machinable tantiron, hard tantiron and tantiron for hydrochloric acid, differ little in composition, but the small fractions of additional constituents are very important. To study their influence, ingots are poured from furnace charges of 1 ton, to which additions are made in very small increments; the ingots are then tested chemically and mechanically. The sulphur and manganese, in their percentages, seem to be of no consequence. The phosphorus is deleterious, mainly probably because it is not uniformly distributed, but concentrated in spots. As phosphorus is added to iron, the freezing point is first lowered, and then, when 10 per cent. of phosphorus is exceeded, rises again,, but the cooling curves are not regular, whilst the freezing point curves of silicon-iron and chrome-iron show a very slow, but steady rise with increasing percentages of those elements. (See Fig. 1.) Impact tests are made on ¾-in. square bars, which are not notched; they break, e.g., under stresses of from 8 ft.-lb. to 10 ft.-lb., against 12 ft.-lb. to 14 ft.-lb. in the case of cast-iron. On the whole, the strength of tantiron is about 25 per cent. smaller than that of cast-iron. The following is a summary of the comparative properties of tantiron and cast-iron (the latter figures in brackets): Density 6.8 to 7.0 (7.3); tensile strength, 6 to 7 (9 to 10) tons per sq. in.; transverse strength, bars of 12 in. by 1 in., 1,600 lb. (2,500 lb.); crushing strength per inch cube, 34 (40 tons); melting point, 1,200 (1,150) deg. C.; hardness, 1.6 (1); heat conductivity, 8 (10); electrical resistance,

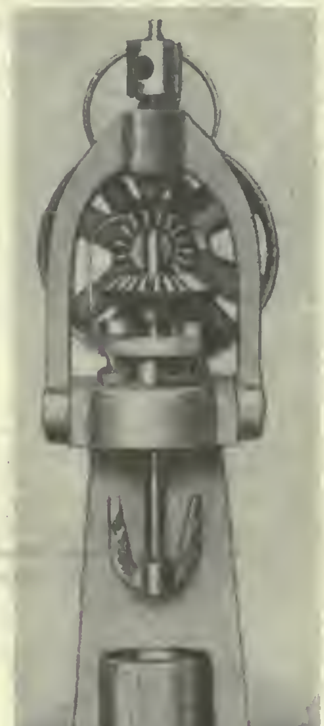

FIG. 4—AUTOCLAVE CUP OPEN ON STAND

10 (8); resistance to corrosion, 1,000 (1); contraction allowance in casting, 3-16 (⅛) in. per ft. As regards other properties, also of other materials, the comparative order for iron, tantiron, lead,

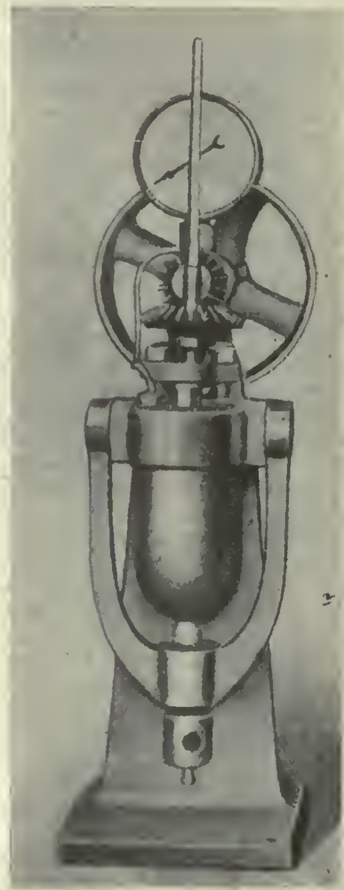

FIG. 5—AUTOCLAVE CUP CLOSED

quartz, stoneware is: Transmission of heat, 230, 215, 115, 28, 20; hardness, 24, 35, 1, 52, 32; density, 7.3, 7, 11.3, 2.6, 2.0; melting point, 1,150, 1,200, 335, 1,900, 1,800 deg. C.

Limits of Corrosion

With respect to corrosion by chemicals, there is generally a first attack, followed by relative immunity under continued exposure. The following figures indicate the percentage losses of tantiron after boiling for 24, 48, 72 hours; the greater action during the first 24 hours is largely due to the already-mentioned skin effect, the outer surface having been changed by contact with the sand in which the tantiron is cast; this skin is removed in the foundry, as we stated.

	First 24 hrs.	Second 24 hrs.	Third 24 hrs.
Sulphuric acid, 98 per cent.	.10	.02	.02
Sulphuric acid, 30 per cent.	.07	.00	.00
Nitric acid, 1.4	.03	.01	.00

Fused sulphur	.06	.01	.00
Fused nitrate of ammonia ...	.00	.	.00

To meet the peculiarities of the material, it is desirable that designers of parts to be made in tantiron should bear the following rules in mind: large flat surfaces should be avoided, corners be

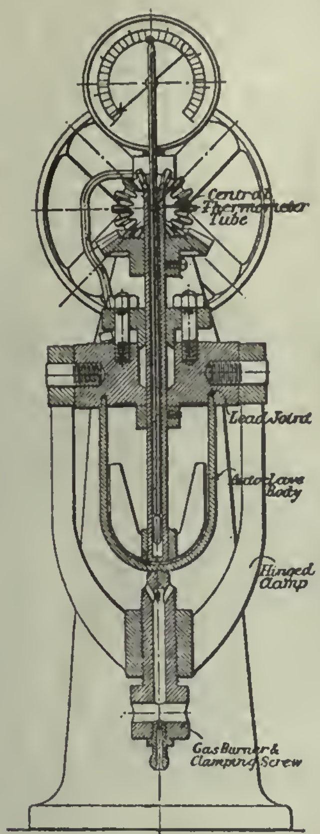

FIG. 6—SECTION THROUGH AUTOCLAVE

rounded; slots be used by preference to bolt holes; facing strips be narrow and of ample height; the effects of expansion and contraction should be well-considered; coring and moulding be made easy, by preference without the use of chaplets to support cores. Among the chief products now made wholly or partly of tantiron, are: acid pans, basins, stills, bleachers, denitrating towers, autoclaves, condensers, pumps, stop cocks, valves, pipes and fittings, electrodes, &c. Frequently a tantiron lining will suffice to prevent either chemical or mechanical erosion. The largest tantiron casting so far constructed weighed 7½ tons.

Moulding

The greatest care is bestowed upon clean moulding, which is mostly done by women, and use is made of rotating strickles in preparing the moulds for parts of circular section. For lining pipes with tantiron, the pipe must be suspended vertically by a flange with the core in proper position, the pipe to be lined being weighted below; if the liquid tantiron were poured into a horizontal pipe, the pipe would curve. This practice is generally adopted for lining iron or steel, wherever possible, and the part to be lined is well dried, but not pre-heated. The adhesion between the iron and the tantiron is said to be good, fusion taking place between the surfaces; the adhesion is tested with the aid of paraffin oil. The lining may have a thickness from ¼ in. up to 1¼ in. and more. The subsequent finishing of the product is largely done with the aid of carborundum wheels and grinders. It is rather curious that the fine tantiron particles torn off by the tools do not spark; there is only a glow. Drills, saws and planers are also used.

The basins for the heating and concentration of sulphuric are mostly of the plain porcelain dish style, but are provided both with a lip and an arc-shaped baffle (not shown); they are supplied also in the Webb and Dyson styles (Fig. 2). The basins are arranged in cascade, so that the hot acid drips from the lips of one basin into the one next below, and the baffle prevents the acid from streaming right over the basins to the lip. Provision for more efficient circulation and stirring of the acid in the basin is made in the "Mackenzie field tube evaporator basins," also supplied by Mr. Lennox; this style has calix shape, being a tube opening out into a basin; a "field" tube fits concentrically into the cylindrical portion and promotes active circulation. Other basins are provided with covers and necks, and made corrugated, and they serve generally also for the concentration of corrosive liquids, such as zinc chloride, lead nitrate, &c.

Concentration of Nitric Acid

The concentration of nitric acid requires more varied apparatus, which have successfully been made of stoneware in the past few decades. When the war broke out, the stoneware works of this country were not able to deal with the demands, and tantiron vessels, which can be made in a few days, whilst good stoneware requires months, were largely adopted. Valentiner plants, comprising a still, condenser and coils, built up of pipes and return bends flanged together, all of tantiron, are now made. The denitrating tower illustrated in Fig. 3 is an interesting novelty. The spent acid of nitroglycerin works consists of diluted sulphuric acid, which has to be concentrated again, and some nitric acid, which is to be regained by distillation. There may also be small globules of oily nitroglycerin which might coalesce if the evaporation were carried on in pans. The tower, 15 ft. high, is built up of socket pipes, 14 in. diameter, and is packed with quartz fragments; the acid enters at the top and steam at the bottom, and the nitric acid and vapours condense in the cylinder by the side of the tower. Nitric-acid stills are also used for the distillation of acetic acid. The autoclaves for making ammonium nitrate from cyanamide at a temperature of 120 deg. C. and a pressure of about 2 atmospheres, resemble one

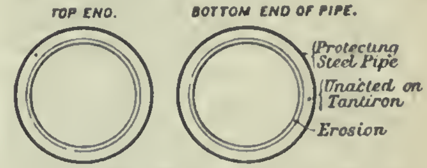

FIG. 7—EROSION OF TANTIRON PIPES IN SERVICE

style of nitric-acid retorts. The outer vessel is a jacket of cast iron, the inner vessel of tantiron forms the saturator; the height is 8½ ft., and the diameter 4½ ft., e.g.

The autoclave illustrated in Figs. 4, 5 and 6 is a clever compact laboratory apparatus, whose utility and handiness will appeal to every chemist. The ordinary autoclave has to be screwed up tightly and unscrewed again each time. In this Lennox autoclave the parts are clamped and unclamped by the use of one spanner, and everything, crucible or cup, stirrer, pressure gauge, burner, is ready for use. In Fig. 4, the cup is seen on its stand open, and the stirrup clamp is turned up. When the cup of tantiron is lifted, and the clamp turned down, the cup is pressed against the lead joint in the cover (Figs. 5 and 6), and the autoclave is sealed; the bolt passing through the clamp, by means of which the autoclave is tightened up, also serves as the gas burner, and the axial stem of the stirrer is hollow to receive a thermometer; the stirrer is actuated by an electric motor.

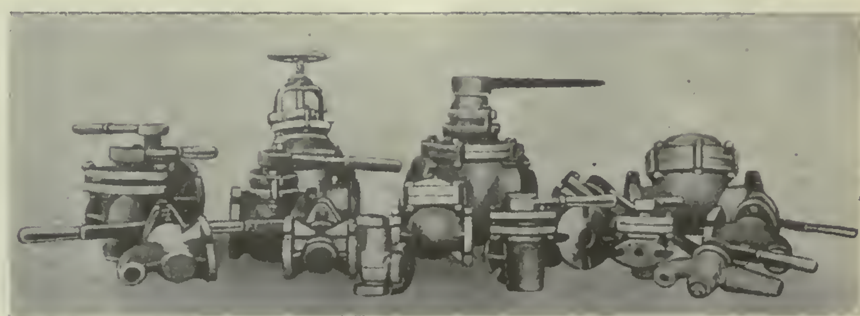

FIG. 8—ACID PROOF VALVES AND FITTINGS

Acid eggs, apparatus for forcing up corrosive liquids with the aid of compressed air, are made of two tantiron cups, joined by their top flanges so as to form a horisontal cylinder with spherical ends and one common flange on the vertical middle plane; they are provided with acid inlet and outlet valves and an air pipe, and are supplied in large sizes. The pumps of the works, reciprocating and centrifugal, do not differ much in appearance from ordinary pumps; the barrels and impellers and pipes are made of tantiron or lined with it. As these parts of hard tantiron cannot be machined or repaired, it is recommended to keep spare parts ready for cases of accident. Centrifugal pumps are supplied for lifting 6,000 gals. of acid or corrosive mine water, &c., per hour, against a head of 50 ft., running at 1,600 r.p.m. Slime pumps, e.g., for conveying the crushed quartz in gold mines, are likewise made of tantiron, to obviate the heavy erosion of the pipes by the gritty quartz particles. For the same reason, tantiron-lined steel pipes are used in the Rand mines, South Africa, for the sand-filling plant When the pillars left in the galleries below are to be removed, the galleries have to be refilled with the finely crushed quartz from the vast white waste mounds which form a conspicuous feature of the district. The spoil is flushed down the pipes with water. The first pipes used, steel pipes, were ruined by 6,000 tons of sand; porcelain-lined pipes were then tried, which could stand up to 50,000 tons; the tantiron pipes, introduced four years ago, are still doing duty, and their life capacity is estimated at 500,000 tons. The 500 ft. of 5-in. pipes put in were delivered in sections of 7 ft. Fig. 7 illustrates the erosion they had undergone by the passage of 106,000 tons of quartz sand under a head of 500 ft. In each case the outer ring represents the steel pipe, the second, intermediate ring, the tantiron remaining intact, and the inner ring the eroded thickness. The erosion is greater at the top, where the sand strikes the pipe than at the bottom, and is not the same in all sections, probably owing to peculiarities of their positions. Similarly-lined steel pipes and tantiron pipes, up to 2 ft. in diam., are in use for ash ejectors, especially on board ship, where heavy erosion and corrosion by the caustic ashes and the sea water have to be guarded against.

In stop cocks and valves of tantiron corrosion by acid sodium bisulphate (the acid cake residue of the distillation of nitric acid from salt and sulphuric acid), erosion by grit, rusting and sticking are the chief sources of trouble to be met. Here, again, tantiron competes with lead and stoneware, and its advantages lie in greater strength and indifference to high temperatures and frost. Fig. 8 shows types of cocks up to 4 in. in internal diam.; a groove is made in the centre of the cock and charged with a greasy preparation of ceresin, vaseline, black lead, and asbestos, which is pressed into the groove by means of a screw. A great variety of cocks, valves, T-pieces, straight and bent socketed pipes, provided with threads, are made in tantiron.

Specialties

Of other specialties, we mention the corrosive-vapour drying and baking ovens, the flat doors and walls of which are lined with sheets of tantiron, which are screwed on. Tantiron can be rolled at about 700 deg. C., but is brittle then. Another specialty is the tantiron electrode for cyanide baths (silver and gold), and also copper baths, &c., replacing iron and other alloy electrodes, which are not insoluble, and very objectionable on this account, or more expensive than tantiron. For the same reason, steel-mixing mills for the manufacture of manganates, the balls and stirrers of other mills, and many apparatus used in the acid and dye and other chemical industries, are made of tantiron.

Foundry work had been carried on in the buildings which Mr. Lennox now occupies for over 100 years. There are 2½ acres under roof, and about 200 people, including 50 women, are now employed. The work of the women, who have all been trained at the works, gives complete satisfaction; excepting in the pouring department, in which men alone are employed, they work in all the departments, in the laboratories, moulding pits and machine shops, as well as in the office, but are under the special control of a lady on the staff, who also looks after their little privileges as to tea and rest intervals, their starting work 10 minutes after the men, and leaving before them, &c. When husband and wife are both in the works, they are not attached to the same department.

Like every manufactured article, tantiron is constantly being improved, and does not claim to have reached final perfection. Acid-resisting materials must possess various properties which are not easily combined, and possibly not capable of combination. A compromise has to be accepted.

ARGENTINE NAVIGATION—ITS ORIGIN AND GROWTH

By R. E.

It used to be a common saying in Australia that New Zealand and the "Union Line" meant pretty much the same thing—the country and the company were so closely interwoven that the one was regarded as the complement of the other, and much the same thing may be said, with certain differences, of Argentine and the Argentine Navigation Company, for along 3,000 miles of river Argentina may be said, without exaggeration, to have its origin in Nicholas Michanovitch, for until he appeared on the scene the river transport of the river and immense territories of Argentina was infinitesimal and of deep sea transport she had none.

It was in 1864 that Nicholas Michanovitch, then a youth of seventeen landed at Monte Video, without friends, without money, and unable to speak the Spanish tongue. The war with Paraguay soon began, and young Michanovitch, taking "anything that offered." obtained employment on store ships, in a comparatively short space of time becoming master of a small coaster at Buenos Aires. Then followed, in 1875, the hiring of a couple of tugs, and the opening of a combined office and store—a single room—and on these small, but, as they proved, secure foundations, Nicholas Michanovitch began to build. The tugs, which at first, he was able to hire, he soon became able to buy, and, as time went on, to add to their number, and when we remember that at Buenos Aires in those days there was no "tying up" ships having to lie out in the river and discharge into lighters, it followed that, with the trade of the port steadily increasing, lighters and tugs became in still greater demand, and the man who could supply them prospered correspondingly. Michanovitch gradually extended his activities, placed an order in England for a cargo steamer, and this vessel was the first of her class to enter the port of Buenos Aires, as it then was—in 1880. An opposition tug and lighterage company was then bought out by Michanovitch, who, by 1889, owned over 30 tugs and lighters, and, by the end of 1889 was the possessor of a fleet of over 100 vessels, and now the rapidly developing trade of Buenos Aires and the Plate ports carried with it a corresponding increase in the, by this time, extensive business of which Michanovitch was the master-mind. Year by year business expanded, and in 1909 Michanovitch formed the Argentine Navigation Company (Nicholas Michanovitch, Limited) which, on the outbreak of the present war, owned a fleet of over 300 vessels, and was described by the Chairman at the R.M.S.P. meeting, in language by no means overdrawn, as "an important concern, with an extensive organization for linking up the South American ports by means of vessels, river craft, tugs, lighters, etc."

From the beginning the Argentine Navigation Company prospered exceedingly. An extract from the chairman's report of December, 1910, reads: "Argentine has over three thousand miles of river available for navigation, and nearly two thousand miles of sea coast. On all this vast extent of waterway the fleet of this company is constantly plying, serving the ports, the townships, and the settlements. Our service across the estuary of the River Plate between the capitals of Argentine and Uruguay, is of invaluable public utility by connecting those two countries. The steamers undertaking these nightly runs are handsome modern boats, equipped with all that can be desired for the comfort of passengers. Another service of upwards of one thousand miles unites Argentine with Paraguay, giving a fast service between the two capitals. Even beyond Asuncion the service continues to the distant town of Concepcion (as far north, almost, as the latitude of Rio), and, at the same time combines a service on the Alto Parana. Fifty ports and townships are in this manner linked up with the metropolis of Buenos Aires and put in touch with Europe. Still another service navigates the waters of the Uruguay to meet the requirements on both the Argentine side and that of the neighbouring republic."

The "War Taurus" Takes the Water at Polson's

Steel Vessel Being Turned Out to the Order of the Imperial Munitions Board—Launching Was a Complete Success in Every Way—Work Held Up For Some Time by Strike

A FURTHER useful contribution to Canada's war effort was made on Thursday, September 19th, when the steel steamer "War Taurus" was successfully launched from the yards of the Polson Iron Works, Toronto. The launch passed off without the slightest sign of a hitch to mar the event, the vessel starting to move with the firing of the gun, and being moored at her berth almost before the disturbance incidental to her striking the water had died away. The "War Taurus" is one of six similar vessels which are being built for the Imperial Munitions Board. The work of building the vessel has been greatly hindered by a strike of the marine steam fitters and helpers, and it has been necessary to launch her without fitting the sea connections, which will cause further delay in the completion of the hull, ready for sea. The strike was occasioned by the refusal of the company to recognize the steam fitters' union and run a closed shop, which the company has never done in its thirty-five years' existence. Without discussing here the merits of the case it is certainly a lamentable state of affairs that when ships are so badly needed the building should be held up for weeks by labor troubles.

THE LAUNCH OF THE "WAR TAURUS"

The "War Taurus" is a steel vessel of 261 feet in length by forty-three feet six inches beam, and a moulded depth of twenty-three feet. She has been constructed under the classification of the British Corporation and her propelling machinery consists of triple expansion reciprocating engines, the cylinder dimensions being H.P. 20½ inches dia. I.P. 33 in. and L.P. 54 in. with a stroke of 36 capable of developing 1,250 horsepower. She has two boilers of the Scotch marine type, 14 feet diameter by 12 feet long, working at 180 lbs. gauge pressure.

Haste Not Everything

Discussing the shipbuilding situation with Mr. Frank E. Wall, the works manager and chief engineer of the Polson Company, the subject of making records in ship building was brought up. Mr. Wall pointed out that building and completing a vessel in the shortest possible number of days was not so desirable an accomplishment as the general public might be led to believe. He pointed out that many of these ships, after a short trial trip, had to be re-docked and considerable time spent on them, before they could undertake a long voyage, but this phase was never referred to in the published reports of the records achieved. He held it was more desirable to take a reasonable length of time for the building and completion of the ship, so that when she was completed she was ready to start on a voyage of any duration without the necessity of dry docking.

There are several more vessels on the stocks in the Polson Company's yard, and it is hoped to launch three more during the early days of October. It is interesting to know, in this connection, that with the exception of some of the auxiliary machinery practically everything else is built from the raw material in the company's shops.

STRINGERLESS SHIPS

By R. C.

Until quite recent times it was considered absolutely essential to the stiffening of the side plating of a ship that longitudinal side stringers should be fitted between the bilge brackets and the beam knees, this being in accordance with Lloyd's rules. Many vessels are now, however, being built without side stringers, compensation being provided by slightly increasing the depth of the beam knees, these modifications being sufficient to satisfy the rules issued by the classification societies. Many advantages follow the elimination of the side stringers. In the first place there is a considerable saving in the cost of construction of the vessel; moreover, there is additional cargo space, and the ship is very convenient to discharge, there being no shelves for the lodgment of such cargoes as grain or coal. Further, the increased depth of the bilge brackets either avoids or reduces the unsupported span of the frame between the bilge brackets and the beam knees, which admits of a reduction in the size of frame so that it is possible to utilize bulb angle frames instead of the built sections provided for by the rules. It is open to question, however, whether it is structurally safe to dispense entirely with side stringers, although the fact that many builders are at least convinced of the advantage which result from this method of construction.

THE "WAR TAURUS" ON THE WAYS

We Want 100 Editors

CANADIAN MACHINERY wants its readers to help edit this paper. There are men in the tool room, in the machine shop, in the pattern room, at the drafting board, in the sales department—all over, in fact, who are good editors. We want them to work for us.

A good editor is a man who can get his ideas over to the other fellow.

CANADIAN MACHINERY wants articles on shop practice, new devices, new ideas. We want stories of how repair jobs have been done, how production has been increased, how you have been helped in your work.

We want anything that has shop atmosphere in it. The man out of the shop cannot be as good an editor for a mechanical paper as the man in the shop. We want an editorial staff that will stretch right across the Dominion.

If you have never written for publication, try it. Your work will be given the fairest treatment here. If you have sketches illustrating your idea, send them along. If they are worked up properly, all right. If they are not, our own draftsmen will attend to this for you.

CANADIAN MACHINERY pays for this work. Some mechanics are making a nice little side line out of this. Besides this, it gives you an added confidence in your work, a new pride in your trade, and it will bring out the ideas of some other fellow who may have worked the same problem in an entirely different way.

In these days of special work on munitions there are numerous ideas that ought to be passed along. Don't take it for granted that all other mechanics have had the same experience as you have passed through. Your ideas may help some person to be a better mechanic.

Address your copy and drawings to Editor, Canadian Machinery, 143 University Avenue, Toronto.

IS THE TRAINING WORTH THE TIME AND MONEY PUT INTO IT?

To the Editor, Canadian Machinery: My attention was attracted recently to a large poster asking for men for munition works, the wages offered being from $4 to $15 per day. As I understood that the days of fabulous wages for the work of sticking shells into an automatic machine had gone by I naturally wondered what particular operation could command $15 per day, and how many of those $15 jobs were vacant. Evidently, if men to fill them had to be procured by display advertising on the hoardings there must be quite a few of them, for generally speaking the men who can command salaries at the rate of $4,500 per annum are not studying the bill boards to find a vacancy. It would seem that these very desirable rates must still be going to the men engaged in the mechanical work, and this occasioned some thought as to the rewards to be gained by the professional man as against the working man.

When we find conditions such that a comparatively unskilled laboring man earns from $4 to $5 a day, and skilled men from $5 to $15 per day, we would naturally think that the men in the higher engineering positions, who must be technically trained as well as practical experienced men, would be drawing salaries in proportion. However, this does not seem to be the case, for the average salary paid to the skilled engineer in the drawing office is not to be compared with the wages paid for instance to a toolmaker. I remember the case of an engineer, and a very clever one, engaged on the design and layout of a large munition plant, who was receiving less than $200 per month, and when the plant was started up alien enemies were drawing $12 and $15 for 10 hours work on shells.

This may be a question of supply and demand, but one is forced to wonder if the time and money spent on training an engineer is in the majority of cases worth the while. Hoping to hear from some of your readers on this question.

Yours truly,
MECHANICAL ENGINEER.

ARE THE SHOPS UNWILLING TO RECEIVE SUGGESTIONS FROM MEN?

Toronto, Sept. 23, 1918.

Editor CANADIAN MACHINERY:—

Sir,—Re your article, "The Foremen That Are Wanted."

Your article opens up a controversy in which most mechanics will bear me out when I say that there are lots of thoroughly good men in the machine shops of this and other cities of Canada who are great readers of the CANADIAN MACHINERY and the allied papers connected with the machinist business.

These same men are also able to instruct how a certain job may be done to the best advantage and in the minimum of time, compared with the methods at present in existence in some of the large shops, where there is a lack of tools and also where jigs could be made for the speedy output of certain operations.

I have in mind one munition firm where I was employed for a period of nearly 12 months and where I was in charge of the machine shop for the greater part of the time. I suggested more than half a dozen different operations, where, had they employed jigs for the production of parts, half the time could have been saved with a great saving of expenses, not to mention the time wasted by the operators hanging around waiting for tools, etc. The outcome of which was, I was politely told, I was to do as the heads higher up said. This is the one chief fault in the shops now-a-days. Needless to say, I got out. I think sometimes that it is a mystery to lots of good mechanics how on earth some firms pay their way at all and make money.

I have now a position with a large corporation where, for system, there is absolutely none in the place whatever. Take, for instance, their class of work. With the addition of one or two machines of the automatic type the output

(Continued on page 370.)

DEVELOPMENTS IN SHOP EQUIPMENT

Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.

METAL SAWING MACHINE

THE cold saw illustrated has been manufactured by the Swind Machinery Co. of Philadelphia to fill the need for an inexpensive yet efficient and practical cutting machine.

The frame is a substantially rectangular housing provided with adjustable clamps, with movable jaws at opposite sides for supporting work or bars to be cut.

The oscillating cylindrical carrier contained in the frame is provided with an eccentrically mounted saw spindle carrying a circular saw. The carrier is rotated through the medium of a circular rack and pinion which automatically feeds the saw into operative engagement with the work.

The drive is of the single clutch pulley type operating the drive shaft and extending longitudinally through the machine frame. The drive shaft is properly journaled at the forward and rear walls of the frame and is secured by end thrust collars.

The automatic feed comprises a stationary rack bar, carried by the frame, a pinion shaft journaled in the carrier, with ratchet wheel on the opposite end, actuated by a bell crank lever, pivoted to the rear end wall of the carrier and eccentrically connected by means of link, which is fixed on the rear end of the saw spindle shaft. A bearing cap at the upper end of the link is transversely slotted, thus permitting suitable feed adjustment, which in turn is actuated by duplex engaging ratchet wheel, thus giving automatic rotation to the carrier.

METAL SAWING MACHINE

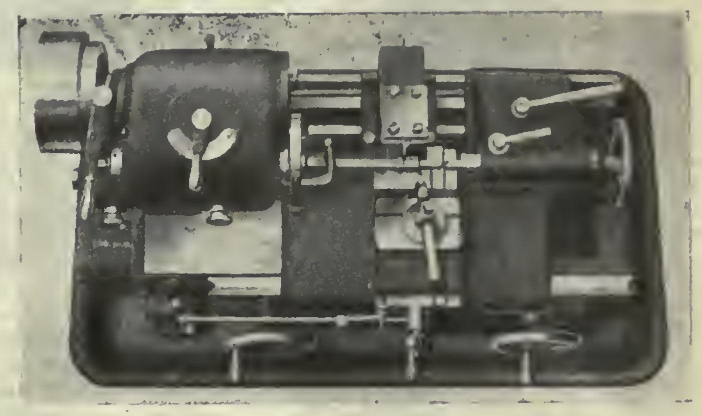
The pump is spur gear connected and located on the inside of the machine frame, thus insuring compactness and freedom from annoying belt troubles. Ample chip space is provided with proper oil drainage and accessible reservoir for the cutting lubricant is contained in frame of machine.

MANUFACTURING LATHE

The Rockford Tool Co., Rockford, Ill., have placed on the market a special lathe to meet the requirements of those engaged in the production of large quantities of duplicate parts. The machine is of simple and rugged design and ample power is provided to enable machinery operations to be performed under the maximum conditions of feed and speed. Since there are a great many lathe jobs performed which consist of machining short pieces of small diameter, a considerable saving in floor space is effected by designing a machine suitable for this work.

The Bed of the Sundstrand Lathe

The bed is of a new design, having separate ways for the tool carriage and the tailstock, the arrangement being such that the carriage can travel to the end of the bed in front of the tailstock. It will be apparent that this allows the tailstock to be set up close to the work, eliminating the overhang of the tailstock centre. The bed is of deep section and ribbed to afford the necessary rigidity. An all-geared type of headstock is employed, which is operated by sensitive friction clutch upon which the driving pulley is mounted. This clutch is manipulated by conveniently located lever and the same movement that disengages the clutch automatically applies a friction brake which stops spindle almost instantly. This permits quick removal of finished pieces and setting up of blanks, and it also permits the spindle to be instantly stopped for measuring the work, etc. The spindle bearings and all the other principal bearings in the headstock are fitted with SKF self-aligning bearings.

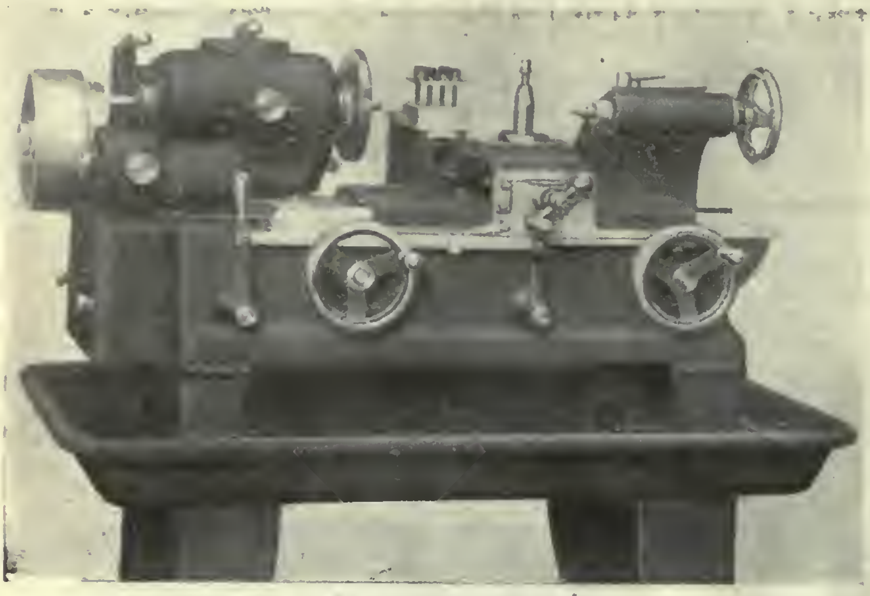


SUNDSTRAND LATHE

Spindle Speed

Three spindle speeds are instantly obtainable by means of a shifting lever, and additional speeds are obtained in series of three by changing two auxiliary gears on the end of the headstock. Four auxiliary gears are furnished by means of which twelve spindle speeds are obtainable. Gears in the headstock run in a bath of oil which assures adequate lubrication. The design of the spindle has been worked out to adapt it for the use of draw-in collets. Movement of the carriage is effected by a screw located between the ways, directly under the tools; this position reduces torsional strains to a minimum. Automatic adjustable stops are provided for the carriage. A special plain rest is furnished as a regular equipment for the carriage. Rear tool-holders of the multiple-tool type for use in the performance of facing and grooving operations, etc., can also be easily mounted on the rear ways where they are entirely independent of the carriage. Cross-feed to the rear tool-holders is operated by a handwheel at the front of the bed and both the front and back tools are equipped with positive stops. A back-rest, taper attachment, draw-in attachment and collets, oil-pump, etc., can be furnished as special equipment whenever required.

The principal dimensions of this lathe are as follows: swing over bed, 9 inches; swing over plain rest, 7 inches; distance between centres, 12 inches; diameter of hole through spindle, 1⅜ inch; maximum collet capacity, 1 inch; diameter of spindle nose, 2⅛ inches; threads per inch on spindle nose, ten; size of cutting tool, ⅝ by 1⅜ inch; length of carriage on bed, 18 inches; diameter of driving pulley, 8½ inches; width of driving belt, 2¾ inches; regular speed of driving pulley, 350 revolutions per minute; number of available speeds, 12; number of available feed changes, 4; floor space occupied by machine, 45 by 24 inches.



MANUFACTURING LATHE

VARIETY SAW

The Variety saw illustrated has been designed for light, accurate work in furniture, cabinet, sash and door factories, or wherever light ripping or cross-cutting is required.

The frame consists of a single box-shaped casting, with a flared base to give ample floor support and that solidity upon which the success of any woodworking machine depends.

The cast-iron table is 40 in. long x 32 in. wide. It is equipped with a removable wooden throat plate 15½"x16" to permit the use of extra thick saws or dado heads. The semi-circular rockers supporting the table permit it to be tipped to any angle not exceeding 45 degrees, while a graduated segment bracket indicates the degree of angle and binds the table firmly in any position.

Fences. The ripping fence is of the double-faced type and can be used on either side of the saw blade. It is supported by a long guide securely bolted to the front of the table and is held in place by a convenient star wheel. A special graduated cut-off fence that can be used on either side of the saw is supplied. This fence slides in grooves cut in the table. The operator can cut off stock with square, bevel or mitre ends, either to simple or compound angles as he desires.

The arbor is of special high-carbon steel 1 7-16 in .in diameter and runs in the best babbitt bearings, accurately scraped and equipped with ample oil reservoirs. These bearings are cast solid to a heavy and well-proportioned yoke that is supported on steel ways attached directly to the main column at such an angle as to assure an equal belt tension regardless of the position of the saw arbor. The arbor is raised and lowered by means of a square thread screw operated by level gears and hand wheel so placed as to be most convenient to the operator. A cone bushing on the end of the arbor permits the use of saws with holes from ⅞ in. to 1½ in. diameter.

The countershaft is placed at a suitable distance from the machine to ensure a long belt pull at the proper driving angle. A ground plan of this machine will be furnished to enable the purchaser to set the countershaft at the proper position.

This machine is manufactured by the Canada Machinery Corporation, Galt.

ARE THE SHOPS UNWILLING

(Continued from page 368)

could be more than doubled from the present, and with a reduction of the staff. There is the same old story here: If you want to be treated right you must not suggest any improvements, or the foreman in charge thinks you are after his job. Still the firms are crying out they can't get good men, when with a little forethought and the introducing of a system they could employ unskilled labor where at the present time they are employing what are generally termed "war mechanics." This is how I have found it to be at the present time and I think there are a favorable number of your readers that will bear me out in my statements.

For myself, I have said that I am far better off as an ordinary workman than being in charge of a number of men, but the old desire gets me after a while, I want to be up and doing.

I omit my name for obvious reason and sign myself

JUSTICE.

ACETIC ACID AND ACETONE FROM CARBIDE IN GERMANY

(Translated for the British Board of Trade Journal.)

One of the results of the war economy in Germany has been the manufacture of acetic acid and acetone from carbide. Acetic acid, the *Norddeutsche Allgemeine Zeitung* writes, was nowhere used for so many purposes as in Germany. A series of synthetic dyes, including artificial indigo, is based on acetic acid, which is also used for important medicinal substances, such as acetate of alumina and acetate of lead, and for innumerable synthetic medicines, such as aspirin, antipyrin, and phenacetin. A number of synthetic scents (e.g., vanillin, sumarin, and ionone, derivatives of acetic acid), which are used for giving an aroma to fruit juice and sweets, are also serviceable as solvents, and for the gelatine process in the manufacture of explosives. The salts of acetic acid serve as indispensable mordants in dyeing and calico printing, and provide an important white for mineral colors. Artificial silk, too, owes much to acetic acid.

It is thus obvious that acetic acid may be put to a variety of uses, and in the last pre-war year its consumption in Germany for technical purposes comprised nearly one-half of the total amount produced, viz., 15,000 tons, as compared with 16,000 tons of ordinary vinegar for human consumption.

VARIETY SAW

Until a few years ago acetic acid was made either by fermenting alcoholic liquors or by distilling acetate of lime ("grey lime," as produced in the wood-distilling works) by means of sulphuric acid. By the first process some 13,000 tons were ob-

(Continued on page 378)

Bill Couldn't Grow With the Old Man Over Him

But He Got His Chance to Develop, and Now That He Has Plenty of Elbow Room and Responsibility, He's Making Good With a Vengeance—He's Got a Title Now That He Likes

WELL, Bill signs himself superintendent now, and he's made good with a vengeance. I don't care how many titles he takes to himself. It's results we're after and if he can get results better with the title of superintendent pinned to him, we haven't the least bit of objection. On the other hand we say, "Go to it Bill."

A Canadian machinery dealer had been telling us about some of his experiences. He isn't a one-shop man. He has seen quite a bit of buying and selling, and knows how the machines are put together from the ground up. And what's more he's doing a lot of business right now in Canada, and unless all signs fail his company is going to continue to do a lot of business in this country both as jobbers and manufacturers and designers.

Well, his story ran along something like this. The conversation had drifted to placing responsibility on men, and developing them in that way. It was pretty generally agreed that a man's initiative would never grow or sprout as long as he was living in an atmosphere of fear and trembling that something he was going to do would not meet with the approval of the "boss." No person seemed inclined to squabble over this, so the dealer went ahead with his story like this:—

"I remember quite well when I was getting my training in the machinery business. After I was taken on the sales force for the Eastern States I came in contact with the men in the shop quite a bit. It was a big concern, and yet it wasn't as big as it should have been. There was the Old Man. He was over all. He was secretary, and head of the sales department. He was everything from office boy to superintendent over the works. He even imagined that he had to lock the safe at night. He really had it in his system that if he were to lay off for a week the whole works would head straight for the dump and there wouldn't be enough left at the end of the week to pay postage on the notice to creditors. Well, the result was this: A man could not develop in that atmosphere. A chap who wanted to get ahead simply had to fight his way, and the way was short and the walls were high. He regarded a man as dangerous and a burden when his salary reached very modest limits. His idea of increasing the revenue was by keeping down the expenses. And he had enough of the stock of the company to make himself felt all over the premises. Salary increases never came there unless they were asked for. and the process of asking required the same qualities that win Victoria Crosses in battle. Well, you can imagine what happened. It was the Old Man this, and the Old Man that. A salesman never felt like doubling up his fists and going out to land a good big order. He had to talk it over with the Old Man first, and his 'thuse would get such a ducking that he would go out like a lame duck. There was never a good deal put across where the man who had done the trick felt like going back to the shop with his chest stuck out and telling the rest of the gang how the thing had been done. The Old Man simply stuck in every person's crop around the whole works, and we were in reality dragging the Old Man with us. He never set the pace for the concern.

Where Bill Comes Into This

"I remember quite well," continued the dealer, "a chap in the shop named Bill. There's always a Bill around a good shop. In fact I don't believe there could be a good shop without a Bill some place around it. Well, this Bill was a mechanic that I learned to admire from the first day I saw him at work. He was a dandy. He knew machinery from the ground up. He was capable of running any machine we had, of doing any operation, of tearing down and putting together and best of all he had the ability to get others to work up to pitch. Bill was the makings of a big man, but the Old Man got him. He was on his trail. He camped on his neck just the same as he did on the rest of us. Bill wasn't developing. He was going to be just plain Bill and that was all. He wasn't going to fill the good big healthy space that he had been carved and fashioned for. Well, to cut this thing shorter, I made up my mind that if I ever got into a place where I could give Bill a chance I was going to send right straight off for him, and see to it that he came along.

"Well, some years after I came to Canada for the Old Man's firm, but now under my own steam. Land, it felt good to be out from under that eternal restraint! I could get out and dig and if the digging was good I got the worms. If it was poor I got nothing. But it was up to me. I didn't have to keep in mind that sooner or later the Old Man would come along and check me up. The business grew here. It has been growing more rapidly of late, and it's going to grow some more in the future. It wasn't long before I wanted a real good man with mechanical training to look after the warehouse end of the establishment which had grown to pretty fair proportions. Did I advertise? Did I go around the city asking this man and that if he knew where I could get a good man? Not much. I knew where my man was. I sent for Bill, and he came.

And Bill Has Made Good

"Some day I'll take you down to the warehouse to meet Bill. He's a dandy. He knows our line of business from A to Z, either going or coming. He can take down any machine that ever comes into the place. He can rebuild or remodel. He can tell a customer almost to a bolt what he requires in the way of equipment, and what Bill says is so, and the trade has come to know it. Do you suppose that I bother with that warehouse now? Not much. When Bill came here first I explained the whole situation to him. We went over the field and lined up what there was in sight. I pointed out that my whole time had to be taken up with chasing business, and the whole staff wanted nothing to do with running the warehouse end of the concern. So we put it straight up to Bill this way: 'Bill, that warehouse is your concern. It's up to you to hop and make it a go from to-day on. Now go to it.' And believe me," concluded the dealer, "Bill hopped, and he made it go, and he's still making it go, and he's the best man in his class in the district. He signs himself to all documents, 'Bill ———, Superintendent of the ——— Co.' He puts that title down as though it was one of the finest things in the world. If Bill's a better man with his title and his dignity why all we say is, 'Reach out and grab for more titles, Bill!' But it does me good to see Bill now and remember the days when he used to be scared to death of the Old Man. Bill is more capable than the Old Man ever thought of being. He can do things that the Old Man would have smothered in their infant stages. And it's all because Bill has elbow room and responsibility. A man can't grow big as long as he has a little man camping on his trail."

Don't Shut Your Eyes To This

MUNITIONS workers are making good money now. In some cases—in fact, in a good many—they have made more in the last few years than they ever made before. There is no doubt that there is some exaggeration regarding the money that is made in some cases. A big sign on a down-town street reads that men are wanted in a certain munitions plant at wages varying from $4 to $15 per day. If we were going out there to work we would ask for one of the $15 a day jobs in preference to the $4 garden variety. As a matter of fact, $15 per day jobs in munitions plants are scarce.

However, there is no use denying the fact that munitions workers are making big money. The trouble is that they are also spending big money. Go into the stores now, and see what is being bought. Silks, laces, furs, and all sorts of finery. Moving picture shows are jammed to standing room only for three performances a day. Every fakir that opens up a stand gets an audience right straight off.

Munitions is the big business in Canada right now. People on the outside hardly realize how the whole industrial machinery of the nation has drifted over to the war order business. It is not an exaggeration to say that munitions and war orders comprise 85 per cent. of the total business moving in the industrial world in this country.

When the war is over and that is cut off, what then?

The purpose of this article is not to discuss after-war trade, but to get the munition worker to look straight at it.

Here is a case. It is not supposititious, but real. A barber who had machine shop training left the barber shop for the munitions business. He had for years been making around $16 per week. His family lived at the $16 mark. His buying power was $16. For three years he has never made less than $45 per week. What happened? His plane of living was higher. His purchasing power had increased almost three times. He was now a purchasing factor of $45 per week as against his old $16. His family tastes came up to the new mark. We will grant that some of the difference would be readily absorbed by the high cost of living. But apart from that there should have been a margin of safety that could readily have been covered by a savings account or an investment in war loans or some other good security.

This family is having a good time. They are not saving money. And that family is not in a class by itself. The word thrift has absolutely been kicked from the premises in a good many similar cases.

The head of that house cannot see past the end of his nose. If he could he would see this:

(1) The war is going to end some day.

(2) The manufacture of munitions will cease about the same time.

(3) His $45 pay envelope may look as though it had been struck with a six-inch shell.

We do not argue that he will be roaming the streets looking for work. But he is now working at an abnormal occupation, and with the elimination of competition he is able to secure wages that he is not capable of making in normal times.

If you are passing through a season of prosperity don't forget that your prosperity is being bought and paid for with the blood of your fellows on the Western front.

Don't forget that your season of prosperity is not going to last forever. And don't let yourself be jockeyed into the fool position of having played the modern role of the prodigal son. Get that word THRIFT into your system, and you will improve your chances of not being dizzy when the munitions business falls off.

The Real Meaning of Success

J. J. WARREN, managing director of the Consolidated Mining and Smelting Co. of Canada, at Rossland, B.C., has announced that the company will give a $500 scholarship to the "son of any employee of the company working at day labor, who heads his class in the matriculation examinations for applied science in the British Columbia University."

The stipulation that the boy shall be the son of a man working at day labor is not a form of patronage. It faces a condition that actually exists, viz., that the son of a day laborer as a general thing stands a very poor chance of getting a course in applied science at a university. Too often the force of circumstances that made the father a day laborer is operating to do the same thing to the son.

The company that gets close to its employees—that sees in industrial life something more than clock punching and dividend notices—that wants the sons of its day laborers to have a chance to occupy better positions—that company is going to succeed in the higher meaning of the word success.

For after all success cannot be measured entirely by the expansion of plants, the paying of dividends or the declaring of bonuses.

Plucked !

REWARDING INITIATIVE IS TO SECURE MORE OF IT

Frank E. Wall, General Manager of the Polson Iron Works, Has Filled Many Responsible Positions

"THERE'S what I mean by initiative." The speaker indicated a small gripping device on his desk. "Of our sixteen hundred men," he continued, "I told you that about fifty study at night. One of these studious boys made that and brought it to me."

The speaker was Mr. Frank E. Wall, general manager of the Polson Iron Works, Limited, Toronto.

FRANK E. WALL

The gripping device was a most practical-looking metal chuck. In size and outward appearance it was not unlike an old-fashioned wooden potato-masher. But that five-inch projection—corresponding to the rounded handle of the potato-masher—was square.

"It will save labor and time hitherto required for squaring ends of stay-bolts red hot under the hammer," Mr. Wall explained. "You know how a stay-bolt is ordinarily put in: the end squared to provide a gripping surface. Then, when the bolt is in place, the squared end is cut off, leaving about one inch protruding, which is riveted tight to the boiler plate. Well, this chuck grips the staybolt without it having been squared, and this"—his hand slid along the squared handle-like projection of the chuck—"this gives the gripping surface required to put the bolt in place."

Mr. Wall leaned back in his chair, an appreciative smile prefacing his next remark.

"I am sending a personal letter to the young man who made that chuck and with my letter a tidy cheque. It may be an incentive to other men in our plant."

"And to other men in other plants," was the unspoken thought of CANADIAN MACHINERY.

Came Early to America

In London, England, thirty-five years ago, Frank E. Wall was born. A year later the Statue of Liberty greeted him and his parents and, in due time, the public schools of the Republic taught him the three R's. High school and University beckoned, but his chosen work called.

Consequently, before his twentieth year, young Wall had completed his apprenticeship and was well advanced in a course of study under the private tutelage of a man who, in the words of his one-time pupil, "is the peer of the best naval engineer that ever put ships on paper."

The year 1905 found Mr. Wall in the United States Navy yards at Norfolk, Va., filling his first situation of importance. From then on he held responsible positions, one an appointment to the engineering staff of the Public Utilities Commission of New York City. The subways, then in course of construction, presented engineering problems that Wall helped to solve.

Along in 1915 the Mobile Shipbuilding Corporation had scouts out for a man capable of designing and supervising the erection of a new shipbuilding plant. Wall's record marked him as a likely man for the job. But Wall himself didn't look older than his thirty-two years. He moved to Mobile, Alabama. The more he heard of the Mobile plant the more he wanted to build it. And he did build it—so thoroughly well that Uncle Sam at war wanted him.

So 1917 found Frank E. Wall with the United States Shipping Board as a supervisor of steel ship construction. And here he remained until the Spring of 1918, when he accepted the position he has since filled with credit to himself and to Polson's.

"Not a book on shipbuilding or mechanics—not a paper worth reading—gets by; study them all," said Mr. Wall. And that from a young man in a big position is a fine appreciation to the technical press.

A photograph? Mr. Wall was persuaded. He found many of work and one of particular interest that had nothing to do with work. It was a snapshot of Mrs. Frank E. Wall and their little family of four.

"I thank her for my success—for eighty per cent. of it," Mr. Wall said seriously in conclusion.

Don't Grouch About the Coal

THEY say that coal is scarce this year, and I guess that guess is right, and you'll shiver by the light of day and have cold feet at night—and you'll have to burn up wood and straw and sift the ashes too, and the chances are your nose will be both petrified and blue.

But they're callin' for the coal this year to make things into steel, to give the Kaiser shells to eat every bloomin' meal.

They're needin' coal to make the steel they roll out into plate, for puttin' vessels on the sea for us to navigate, and cart across the men and guns, and stuff for them to eat, when they're proddin' at the Germans for to keep 'em in retreat.

They're needin' coal to make the steel that builds the railway track, that carries up our guns and men to beat the German back.

They're needin' coal to run the plants and keep the wheels goin' round, to make the fightin' tools we need to rescue Belgium's ground. And we're needin' coal for this and that, for work what's stiff and stern, so there aint a great pile left, me boy, for you and me to burn.

But some folks go a-shiverin' round and grouch to beat the band, 'bout how they use us stay-at-homes what's dwellin' in this land.

There's howls from every little joint, there's squeaks from every store, there's groans from every little squib who runs a two by four—the whole blame thing is run dead wrong, the coal delivery cart should come around each workin' day and ask them where to start.

Pull on some woolly socks, me boy, get on a flannel shirt, the kind what makes you squirm a bit and say things short and curt—get on some boots with 'ob-niled soles, and take steps big and bold—and for the love of Mike, me boy, forget about the cold.—Ark.

And there's not much sympathy for old H. T. either.

MARKET DEVELOPMENTS

Some Signs Now of Improving Conditions

Larger Shipments of Plate May be Secured—Tin Comes to Point Below the Dollar Mark—Some Talk in Trade Circles of Bringing Out New Style of Shell

FOR the first time in many months it is safe to say that there are signs of a little improvement in some marketing conditions. The plate situation, which has been almost hopeless, shows signs of improving. And the Canadian allotment of material from United States points has been increased by enough tonnage to make the difference noticeable. The shipyards look to the government for their supplies now. Mills at the big producing points in United States have been concentrating on plates for some months, and the result is that there are indications of the demand being overhauled.

The war orders this week from American headquarters in France call for barb wire and steel rails. There was a cessation some days ago in the call for barb wire, but it is probably figured out that new gains can be held move readily with barb wire than with men.

Canadian shops hear rumors of a new shell being brought out in the very near future. It will probably be a changed form of a projectile at present being made largely in this country. Although there is nothing definite in the plans so far, it seems possible that something resembling a streamline shell may be brought out, the claim being that it will have a greater radius in gun fire.

Canadian dealers in machine tools report a normal amount of business with the usual searching around to try and get their deliveries attended to. Dealers in supplies are not certain about deliveries of high speed goods. It is certain that from now on there will be greater delays in this line.

The scrap metal situation is almost at a standstill here. Dealers and consumers tell different stories. The latter state they are having trouble in securing enough good scrap to make up for the shortage in pig iron. The dealers on the other hand, claim that the steel mills and the foundries are full to the roofs of all the scrap they need. There is very little business moving at present through the scrap dealers' yards, but on the other hand there are a large number of sales being made direct from the producers to the melters.

Tin still comes under the dollar mark, and is selling around 95c. This is quite a come-down for this metal. Only a few weeks ago futures of three months were quoted at $1.50, a long cry from the pre-war average of about 30 cents.

MONTREAL SHIPYARDS ARE NOW GETTING BETTER PLATE SUPPLY

Special to CANADIAN MACHINERY

MONTREAL, Que., September 26.—Unabated activity continues throughout the district with munition making the outstanding feature. In addition to the large order recently received by the Canada Cement for 9.2 inch shells for the American Government, it is reported that an aditional allotment for this size shell has been given to the St. Lawrence Bridge Co. Plans are now being prepared for the new plant of the Canada Cement Co. and building operations will be started at an early date. Several local plants are now working regularly on the forging of the 155 mm. shells and machining operations are rapidly progressing to the production stage. Some delay has been experienced through the inability to obtain necessary machinery on schedule time.

Tension in Steel Situation

No relief has been given to the general steel situation and conditions here are still marked by an extreme shortage in many lines. The scarcity of pig iron has virtually eliminated the commercial market and many foundries operating on this class of work have had great difficulty in meeting the trade requirements. In some cases business has been partly maintained by using larger quantities of scrap, but even here the available supply is not equal to the demand. The War Trade Board will only furnish the raw material to those working on the most essential war enterprise. This also applies to other lines of steel activity so that considerable tension is felt in general manufacturing establishments owing to the inability to obtain suffcient steel for repairs or replacements. The constant demand for light plates has caused a drain on the dealers and no 3-16 inch plates are available in Montreal. This is a size constantly asked for owing to its suitability for tank repairs and replacements. The importance of this phase of industrial requirement has apparently not been fully recognized by the War Trade Board and essential activities are in danger of suspending business, in part, for want of facilities to maintain maximum production.

One dealer here states that he could obtain all his requirements from Pittsburg if the War Trade Board at Ottawa would only sanction his efforts to secure the necessary material. To this end the dealer is going to Ottawa to interview the Board on behalf of those manufacturers in need of this and other material required for plant maintenance.

A feature of present conditions is the satisfaction among Canadian shipbuilders over the regular shipments of plates from American mills and in most cases the yards here are nearing easy street respecting their requirements for present and early future activity. It is the opinion of dealers here that the plate situation may shortly take on an easier tone, as a result of the present large production, a factor that will influence the market once the yards are supplied with ample material.

Metals Slightly Easier

The metal situation is not marked by any special developments but an easier tone seems apparent in tin, spelter and antimony. Difficulty is still experienced in securing supplies as it requires authorization of the War Trade Board before requirements can be filled. This often entails delay in obtaining shipments. Ingot coppers continue steady on regular demand with quotations firm at 31 and 32 cents. Tin is coming through more regularly and dealers report a relief in the situation; quotations have declined and the price asked averages $1 per pound. Supplies of spelter are more plentiful and quotations of 10¾c show a decline of ¼c per pound. Lead is unchanged at 10½c, with the demand normal. Antimony is lower on a well supplied market, this week's quotation of 16c being a decline of ½c. Aluminum demand is normal with quotations firm at 50c per pound.

Normal Machine Demand

Activity in the machine tool industry has not been pronounced but the demands are still sufficient to maintain considerable interest among the dealers. Inquiry for some heavy equipment suitable for the 9.2 inch shells has featured the week's business and some sales have been recorded. The requirements for tools for the 155 mm. shells are still unfilled but this is owing to the non-delivery of equipment now on order. Definite delivery on shell machinery is still an uncertain factor, especially where tools are brought in from the States. Considerable activity is being maintained in used equipment that can be adapted for use on the American shells. In some cases this is adopted as a temporary expedient while awaiting shipment of new machinery.

Good Demand for Steel Scrap

With the bulk of the trading virtually controlled through agents of the Imperial Munitions Board, the business passing through the dealers' hands is confined to general activity. Where material is wanted in a hurry the consumer will often apply to a dealer for supplies as the latter will generally give the matter immediate attention, whereas considerable indifference has frequently been shown by those handling the scrap for the Imperial Munitions Board. The demand for steel scrap is very constant and the visible supply is far from adequate to meet the full requirements of the trade. This is particularly true as to cast iron scrap which is taken up quickly owing to the inability to secure pig. The market in scrap metals is dull but a steady business is still carried on by the dealers, who are called upon to supply the needs of the smaller manufacturers. Few price changes are effective, the market generally being firm and strong. Cast borings are now selling at $11 per ton on good demand. Stove plate is scarce with the week's quotation of $32 showing an advance of $2 per ton.

POINTS IN WEEK'S MARKETING NOTES

A new shell may be brought out, the lines of which will be changed to give a greater taper at and toward the base. Greater radius of fire is the end aimed at.

—

The allotment of steel given to Canadian industries has been increased about 50 per cent. in the last few weeks.

—

Tin is selling below the $1 per pound market, as against probable $1.35 to $1.50 quoted a month or so ago. Pre-war prices were around 30 cents per pound.

—

U. S. dealers advise Canadian trade that deliveries are not likely to be as prompt during the coming months, especially for supplies in high speed goods.

—

The scrap metal situation is almost stagnant at present. Sales are not numerous, and yards, the dealers claim, are well stocked with material.

—

There is a big call for barbed wire for the Allies in France. Only a few weeks ago it was announced that little was needed. Apparently it is considered better to use wire to hold new lines than men.

—

Munitions shops in Toronto report in several cases that they can secure all the labor they require. Tool makers, though, are in demand at several places.

—

The big call now is for shell steel and rails, both of them indicating and following the programme of the offensive on the Western front.

—

American steel trade is greatly taken with the idea that the present advances in France are aimed at the district in which Germany gets the great bulk of her steel.

NEW SHELL MAY BE BROUGHT OUT

There is considerable talk about the changing of the style of one of the shells now largely made in Canadian shops, and for which large contracts are still unfilled. It is known that the British have given up the use of the large shells as made here now, and that the Germans are securing a much larger range by having changed the construction of the shell.

Of course it will be some time before any changes can be made here, but the matter is being discussed. The principal idea will be changing the formation of the base of the shell. This may be done by the introduction of a tapering line, giving the shell a streamline effect, to use an automobile term. The flat end now in use has the effect of producing considerable vacuum or suction in its wake, by the nature of the air waves that it brings into existence. The changing of the lines of the shell would be done with the idea of reducing this as far as possible. It may be that some of the Canadian plants will be putting in shops for the turning out of this new product before so very long.

SITUATION EASIER NOW IN SOME LINES

Larger Amount of Material Will Be Sent Here From Across the Border

TORONTO.—"It's all a matter of making deliveries. That's more the point than the securing of the sales." That's the way one big firm sized up the situation to-day, and it seems to be the experience of a good many lines that are catering to the munitions industry. Deliveries from United States points are not so prompt as they have been, and the indications are that they are not going to improve either.

It looks as though the situation in some lines might be going to ease up a little. At least the trade feels that prospects are better than for some time past. For instance the business of building ships in Canada is now looked after by the Ottawa authorities as far as the supply of material is concerned, and the jobbers are no longer booking the plate business for the yards. Of course that may mean that the jobbers will get less material, but it also means that there is more material coming to the country. As a matter of fact that is the case.

The Canadian Allotment

Toronto warehouses are far from well stocked in plates or sheets. But they are expecting that trade in plates will be easier. They have assurance that the Canadian allotment has been increased by almost fifty per cent. per week. This has been made possible by the cutting off of industries in the United States that could not come up to the classing that would put them down as essentials. The output of plate has also been increased by changing a large number of mills from rolling sheets. Steel is shipped to Canada at the rate of 1,500 tons per week. Of course that refers to material heavier than No. 11 gauge. There is a large amount of stuff coming in under that size, though, and there is a tendency to get consumers to use the lighter material. For instance a requisition for flooring for a military hospital is turned down at Ottawa and the advice given that a sheet lighter than 11 should be secured.

Figure It Out Themselves

Local dealers have received schedules showing just what the various ratings given by the Washington authorities mean. This is done so that jobbers and others can study the list and find out for themselves just where they stand in the line. The chances are that there would hardly be room in Washington for enough clerical help to figure out where all the varied interests stand on the preference and priority lists. As a matter of fact Ottawa shows a tendency now to weed out orders more strictly than was the case a few months ago.

There have been no price changes, and it is not likely that any will be made in the next few weeks, although that is a dangerous statement to make.

The situation does seem easier in so far as the securing of material is concerned, but there is no possibility of the supply getting neck and neck with the demand and creating a surplus.

The Scrap Metal Field

There does not seem to be a very large volume of business moving through the local yards. The dealers are very positive in their statments that there is a great deal of scrap metal in the yards of the steel mills and the foundries. "In some places they are fairly clogged with scrap, so much so that they are asking that deliveries to them shall be deferred for a few weeks," declared one dealer. And there are a good many foundries that have never had so much scrap under their shed roofs. I am not inclined to take very seriously the stories we hear about a shortage of material. There is nothing to indicate any such thing. Prices are not going down yet, but one thing is certain, and that is that they are not firm. As soon as a seller or buyer comes in here the first thing spoken of is a lower price for scrap. There is no saying where it may lead to."

No price changes are noted in the local market this week.

Deliveries Are Slower

Representatives of several American firms were in Toronto to-day. They advised agents in several cases that deliveries would be slower in future than for some months past. Recently from three to four weeks has been a safe working distance on orders for supplies, especially in high speed lines. "It looks as though from ten to twelve weeks will be the best we can do now," stated one of the dealers. "This means that Canadian dealers will have to stock more extensively, or that big jobbers in United States will get a bigger share of the business.

The supply business has been great during the last month or so. In fact it is some time since there has been such a volume of business passing as has been registered during the last month.

Tin Below Dollar Mark

Tin is trading below the dollar mark. Its career has been a wild and a merry one, for not long ago futures were looking good for $1.50 a pound, whereas tin used to sell around thirty cents. There has been a good deal of wind and speculation pumped into the tin situation. Of course the shipping facilities have been none too good, and the chances are that a good many bottoms with their tin cargoes have gone to the bottom of the ocean. But even so there was nothing to warrant that $1.50 flight, and the fact that the trading is to-day going on between 90 and 95 cents shows that a saner level is being rapidly reached. Prices of other non-ferrous metals remain unchanged.

WILL FINE FIRMS USING PIG IRON FOR WORK THAT IS NOT ESSENTIAL

Special to CANADIAN MACHINERY.

PITTSBURGH, Pa., Sept. 26.—Military tactics certainly change rapidly. It is only a few weeks ago that a light demand for barb wire was noted, because the Allied forces were advancing. Now there is a tremendous demand for barb wire, and it does not mean that the forces expect to stop advancing. Apparently it is considered better to hold gained ground with wire than with men. Heavy orders for barb wire have been placed in the past few weeks, over 50,000 tons, and 150,000 tons or more is immediately on the boards. The size of individual orders, however, is not indicative, as the time element in delivery enters. It is more illuminating to note that the barb wire making capacity, running the usual single turn, is about 50,000 tons a month and the authorities are considering the making of arrangements whereby some of the barb wire departments will run a night turn also, because 50,000 tons of barb wire a month does not seem to be sufficient. The wire makers seem to expect the demand to continue throughout the war, hence they have become concerned as to the large tonnages that will at some time or other be left unemployed. They have pointed out, therefore, that the painted barb wire commonly used in the military operations deteriorates rapidly and is not salable in large quantities for ordinary purposes. Hence they suggest that a larger proportion of the orders be for galvanized wire.

More Steel Conservation

Week by week the military operations call for more steel for direct use, this being a reflection of the aggressiveness of the Allied forces and the advances they are making. The increases are chiefly in shells and rails, although there are many other items. As the raw steel supply is only so much, there must be further curtailment in the consumption of steel for the less direct war purposes, and every finishing line in the steel industry that can possibly yield any steel for the direct purposes is being minutely studied. Illustrative of the fact that the War Industries Board is overlooking no tricks, however unimportant relatively, the tin can, apparently insignificant, continues to receive close attention. Our letter a week ago noted that the allotment of steel sheet bars to the tin plate mills, representing hitherto a full supply, had just been cut by 30 per cent. for the fourth quarter of the year, the occasion being the close of the canning season. It turns out that did not end the case. The conservation division of the War Industries Board has since been holding daily meetings, one line per day, with the packers of various non-perishable food products, for the purpose of arranging a curtailment in their tin plate consumption. It will be understood, of course, that at no time has any tin plate been allowed to go out except on Government orders and for food products. The expectation is that the absolute requirements in tin plate will be so curtailed that it will be possible to get along with the tin plate mills operating at still less than 70 per cent. of capacity. As noted in last report, it requires about a million two-pound cans to release the amount of steel needed to provide rails for one mile of track, so that it requires a great deal of industry on the part of the Conservation Division to enable General Pershing to lay more miles of track for the big guns that will be pointed at the Metz stronghold, and for other purposes. Incidentally, it may be mentioned that the American steel trade is quite thrilled by the idea that the advances in the Lorraine district are aimed at the territory whence the enemy obtains the great bulk of his steel.

How About Pipe?

Conservation of steel in connection with tin plate is only one item. A meeting is scheduled for to-day with the pipe mills, to consider how much curtailment in the use of steel for pipe making can be effected without serious derangement to the supplies of pipe for direct war purposes for shipbuilding, and the most essential commercial operations. With the greatly increased barb wire demands there will be no further curtailment in wire manufacture as a whole, but some wire products may yield wire to be made into the barb variety. The merchant bar mills are being given further consideration.

For the time being at least there is to be no further curtailment in steel for sheet mills. The supply permitted an operation of about 57 per cent. of capacity in July and the August average was just a shade higher, while present operations are close to 60 per cent. Sheet requirements for war purposes have increased somewhat in the past few weeks and with a 60 per cent. sheet mill operation there will be less sheets for the preference industries, but more for direct war use.

The 33,000,000 Semisteel Shells

Foundrymen are making progress in their study of the semisteel shell program, referred to in last report, the Ordnance Department having announced that it requires 33,000,000 semisteel shells in the next ten months and that it expects the major portion to be made in this district. While a definite announcement was made, detailed in last report, as to the sizes of shells and the description, whether shrapnel or high explosive, it is now very definitely rumored that the department wants more gas shells than shrapnel or high explosive and it may be therefore that the total of semisteel shells will exceed the figures already given.

Local foundrymen do not expect to encounter much difficulty in making the shells to specifications, provided they are furnished the pig iron, and there's the rub. There has been no free pig iron in this district for months, all the output going on contracts involving the filling of war orders or on allocations either for the filling of war orders or for export. The proportion of foundry iron in the total make has been unprecedently small and this foundry iron has been going for the manufacture of mill and other machinery and quite essential requirements. A general committee for the country was delegated a fortnight ago to seek cases of foundries employing pig iron for purposes that could be dispensed with, but indications are it has found very little. A general meeting of pig iron manufacturers and the War Industries Board was held in Washington last Monday to discuss the problems of increasing production and allotment of foundry iron orders in connection with the semisteel shell orders that are to be placed. This was one of a series of meetings aimed chiefly at speeding up production, the pipe, plate and structural shape makers to be met in turn, one group each day.

Coke and Pig Iron

All the investigations thus far have pointed to the same conclusion, that the chief barrier to a heavier production of steel is the quality of coke that many furnaces are forced to use. There are other barriers, but this is regarded as the chief. Coke production in the United States in the last week reported upon was the largest on record, with but two exceptions, and the gain in production, compared with the rate in 1916, would, by proportion with the 1916 pig iron output, compass a pig iron output now at the rate of 44,000,000 tons per annum, whereas for several months past the rate has fluctuated within the limits of 40,000,000 and 41,000,000 tons. A comparison of the number and capacity of furnaces in blast, considering their past performances, also indicates that with similarly favorable conditions the rate of output now should be close to 44,000,000 tons a year. With more pig iron, more steel would be made. The Fuel Administration is increasing its inspection force as rapidly as possible, and purposes to penalize, in price, all coke that is not up to standard in quality. It appears that operators and miners are both in part responsible, some operators being less careful than usual, while miners are not careful to take out clean coal, and any refuse mined increases the ash in the coke and thereby reduces the daily output of the furnace using it.

AUTO AND STOVE SHOPS ARE TAKING ON WAR CONTRACTS NOW

Special to CANADIAN MACHINERY.

NEW YORK, Sept. 26.—Machinery manufacturers and dealers are receiving a number of orders for shop equipment from manufacturers of small arms, shells and airplane motors. The Government is also placing direct orders for equipping machine shops at shell-loading plants and at army cantonments. Provision is also being made by the Ordnance Department to increase capacity of arsenals for making large calibre guns and the Navy Department is constantly buying machinery to be installed at Navy Yards and repair shops.

Several new contracts for automatic pistols have been placed by the War Department and similar contracts are pending, while manufacturers receiving these contracts are buying additional tools. The Winchester Repeating Arms Co., New Haven, Conn., and Landers, Frary & Clark, New Britain, Conn., have already closed on fair sized lists of tools for making pistols. A contract has also been given to the National Cash Register Co., Dayton, Ohio, for army pistols and a large similar contract is on the point of being closed by a Philadelphia company that will require several hundred Lincoln type milling machines and other tools.

The Stove Foundries

Stove founders are rapidly taking on war work including several large contracts for semisteel shells of which about 20,000,000 are wanted by the Ordnance Department. Several of the large pipe shops are already casting such shells and other founders are rapidly converting their plants for similar work. Rathbone, Sard & Co., stove makers, are buying machining tools for semisteel shells which they will cast at their Albany, N.Y., and at their Aurora, Ill., plants. The Michigan Stove Co., Detroit, and the Foster, Merriam Co., Meriden., Conn., have also taken shell contracts and are soon expected to enter the market for machine tools. The Savage Arms Corporation has placed a $125,000 order for tools for its Philadelphia plant, recently acquired from Isaac A. Sheppard & Co. Gun mounts for 3-inch guns will be manufactured. Machinery is also being moved from the Sharon, Pa., plant of the Savage Arms Corporation, and also from the plant of the Defiance Manufacturing plant at Philadelphia, which was recently acquired by the Savage Arms interest.

New Arsenal

The War Department has purchased several tools for each of 27 cantonments for equipping machine shops and the Government has also purchased several hundred tools for machine shops at shell-loading plants. The Ordnance Department has secured a tract of land at Philadelphia as a site for an arsenal to produce large calibre guns; $136,405 was paid for the land, and bids are now being taken on additional buildings to be erected at the Frankford arsenal.

The Navy Department has secured under a twenty-year lease the water front property on New York Bay belonging to I. T. Williams & Sons, for the building of a large dry dock and ship repair works; the property has a water frontage of 1,500 feet and the aggregate rental is about $1,300,000. The Government has also taken over the plant of the Merritt-Chapman Derrick & Wreckage Co. in the same section, which will be utilized in ship repairing and reclaiming work.

Auto Shops Changing

Automobile manufacturers and makers of automobile parts are more actively buying tools for war work. The Hudson Motor Car Co., Detroit, has inquiries out for shop equipment which will permit the manufacture of 2,000 155-mm. shells a day. The Ford Motor Co., Detroit, and the Buick Motor Car Co., Flint, Michigan, have purchased additional machinery to increase output of Liberty engines. The Ford Co. is also still buying for its Hamilton, Ohio, plant and other purchases are contemplated for tools to build 10,000 two-man tanks. The American Brake Shoe & Foundry Co. has placed orders for a portion of the 150 machines called for last week, to be used in the manufacture of guns and projectiles. The H. H. Franklin Manufacturing Co., Syracuse, N.Y., is placing orders for machine tools for airplane motor parts. It has recently taken orders for crank shafts from the Pierce-Arrow Co., Buffalo, and the Wright-Morton Aircraft Corp.

IRON PRODUCERS WANT TO GET HIGHER FIGURE IN NEXT QUARTER

ALTHOUGH it will be some time before a definite announcement will be made regarding the matter, it is quite apparent that the iron interests in United States are pressing for higher prices for pig iron for the next quarter, and it wouldn't cause any surprise were an announcement made to this effect. The foundry pig iron producers decided at their meeting that their case must be presented separately at Washington and not through the General Steel Committee. It is well known, though, at Washington that there is little encouragement to the plea for higher prices. American points of production reports as follows:

Pittsburg.—It is a matter of fact that hardly any sales are being made here now at all. The entire output of pig iron that is not used by the steel companies is being allocated by the Government, so that no new sales are being made. It is also claimed that very little iron has been sold for the first half of next year delivery.

Chicago.—The allotments of pig iron that are being made in this district are so large that there is a serious problem ahead of the furnaces in filling them. Some rather peculiar situations are developing, too. It is natural for the furnace men to want to take care of their old customers, all of whom are on important Government work.

St. Louis.—Some of the foundries in this district are having a hard time in lining up with the essential industries. Notable among these are the stove foundries who are so limited in their domestic output as to be on the verge of shutting down. There is nothing to indicate that there will be much improvement in their business in the near future.

New York.—At the recent meeting of the pig iron manufacturers some of the furnaces from Tennesee showed actual costs amounting to 40 dollars a ton, and some of the Pennsylvania men also assert that their costs amounted to $38 a ton. A good many of them state positively they are losing money and cannot continue in business.

Cleveland.—The scarcity of pig iron is growing rather acute here, and there is nothing like enough to go round. Stocks in the furnace yards are becoming very low and many of the consumers have only a few days' supply.

Many of the allotments made by the Government call for delivery of iron to small and almost unknown melters, who have never had any dealing with the pig iron men before. However, there is no choice in the matter and the orders have to be filled.

Philadelphia. — The agitation for higher price for pig iron is going on strong in this district. It was stated at one of the recent meetings of the steel men here that out of a total production of iron of 8 million tons at least one-eighth of that amount is now being made at an actual loss, and it was also claimed that producers whose costs exceeded selling prices cannot continue to operate under these conditions, and the claim is also made that Judge Gary has agreed to press the claim for higher prices for iron at Washington.

Buffalo. — Government allotments practically take up the entire output of the furnaces here. Transportation is a little better than it has been for some time past, but furnace men are making all possible efforts to speed up shipments and get their books cleared up before the setting in of winter business.

DEALERS IN SCRAP SAY THERE IS LITTLE MONEY TO BE MADE NOW

THE scrap metal situation on the American side is that more and more it is coming under the control of the Government. There is an agitation on in a great many places for an increase in the price, but so far has met with very little success. The state of the trade in the principal points in U. S. is as follows:

Pittsburg—Very few sales are being made through the yards here, as the entire output of much munition scrap is taken by the Government. It is positively stated that no advances will be made in prices of any kind of scrap, and it is also claimed that a few reductions may be looked for. The supply of scrap is reported as being fairly large and several dealers report that they are moving more material to customers than for some time.

Chicago—The general situation in the scrap market here is one of a large demand and a small supply, there apparently being not enough scrap in existence. The demand is not for any particular line, but it is very general, and shipments are wanted quickly.

Philadelphia.—The embargo that was placed on shipments of borings and turnings to blast furnaces which was recently put into effect has not resulted in securing the amount of material that was expected. Trading is done at the Government maximum in nearly every case.

Buffalo.—There is a very active demand here this week for practically every line, and there is an equally marked scarcity of materials to meet it. Stocks in the yards are very low for this time of the year, and the dealers are unable to gather sufficient quantities to equal anything like the tonnages that are being called for. The labor situation here is also very bad, and it makes it extremely difficult for the yards to sort and handle the material that is being offered.

St. Louis.—There has been quite a readjustment of prices here in regard to scrap, and this is being helped along by the fact that railroads are not being permitted to offer cast scrap of any grade or class, this also being true of car wheels, brake bars, arch bars, etc., while very few axles are being put out for general bidding. Many of the consumers here are using material of all classes and grades and there is nothing offered at the present time which does not find a very ready sale.

Cleveland.—There is a very heavy melting steel, but the limited supply is restricting the sales.

Cincinnati. — Number 1 machinery scrap is in very heavy demand here and the dealers in nearly every case are able to obtain without any difficulty amid the Government maximum price of $34.00 per gross ton delivered at consumer's plant.

ACETIC ACID AND ACETONE

Continued from page 370

tained in Germany in 1913; by the second, some 20,000 tons.

The dry distillation of grey lime produces acetone, which is used for soaking nitro-cellulose and also as a solvent. In the last years of peace it began to receive attention in connection with artificial rubber, and this utilization of acetone took on great dimensions during the war, so great that neither the German nor the Austro-Hungarian timber industries were able to meet it. Before the war the former worked up some 17,000 tons of home-produced grey lime. Apart from that, 20,000 tons of grey lime were imported annually from America, and this supply has now ceased owing to the blockdale.

To fill up the gap a new industry came into existence—the synthetic production of acetic acid and acetone from calcium carbide. Calcium carbide, which is made of lime and coke, can be manufactured in Germany in unlimited quantities. The present output is estimated at 400,000 tons. The establishment for making acetic acid and acetone out of calcium carbide is the Dr. Alexander Wacker Company for the Electro-Chemical Industry.

After giving a brief technical description of the processes adopted by this company, the writer proceeds to say that before the war 3.4 million cwt. of potatoes were annually fermented into acetic acid. In addition, some 4 million marks' worth of grey lime was imported into Germany. In contrast with this the factories which have been opened during the war for synthetic manufacture of acetic acid from carbide, that is to say, out of home products, are well able to satisfy the whole German requirements of acids and vinegar. The new industry promises to be very vigorous, and there is little fear that in the future so valuable a foodstuff as potatoes will be turned into acetic acid.

Germany has come to the end of her tether in many vital raw materials not produced in enemy countries. Teuton factories are, and will be more, hungry, therefore, for raw materials when the war is over. Germany cannot manufacture without them. Does she deserve any contribution in raw materials from Canada? Germany, for her own domestic requirements and export trade, will be in the market for enormous supplies of raw materials which, with the demands of these portions of Europe which have been devastated, will tax for some considerable time the rest of the world to supply.

The most sanguine optimist, however, is now obliged to view the future with grave concern. A famine in Europe, accompanied by a serious dearth in raw materials, are not only possibilities, which cannot be disputed, but there is every evidence to indicate they cannot be averted.

Organizing for the Production of Forgings

The Proper Forging of the Shell Has Much to do With the Success of All the Following Operations—New Machine Designed For Gauging the Length of the Billets

By J. H. RODGERS, Associate Editor Canadian Machinery.

MANY factors are involved in the manufacture of munitions that control or regulate the output of the plant, but the pivot upon which the entire organization depends for maximum production is undoubtedly the forging of the shells. The efficiency of this operation is the keystone that assures and maintains the smooth running of the other departments and permits of an undisturbed flow of shells through the hands of the inspectors and the subsequent machining. Unless the forged blanks are reasonably accurate, both as to dimensions and to physical structure, it is impossible to expect that the resultant machining can be performed with the greatest degree of effectiveness. It is therefore necessary that every attention be given to the various details of this department to avoid an excessive percentage of rejected shells.

The past four years of practical experience has enabled shell manufacturers to provide facilities that will best meet the requirements for maximum production. Equal in importance to the equipment required for the work is the arrangement of this equipment. Where large quantities of a product are being turned out daily it is very essential that no overlapping takes place during its progress through the various sections of the plant. In order to conserve the energy of the workmen, so that the same may be applied to useful effort, appliances are invariably provided that minimize the physical exertions when the men are handling the work. This is particularly true in relation to the forging of munitions, where operators are subjected to the extreme heat of the furnace and the heated shells, and likewise to the steam and smoke that are unavoidably present during these operations. After the forging process has been completed it is highly desirable that the shell be removed from the vicinity of the presses as early as possible to relieve the men from the heat radiation. In this plant a chain conveyor has been installed, parallel to the line of presses, and the entire length of the shop. At the end farthest from the forging presses the shells are transferred to another conveyor, placed at right angles to the primary one. At the transfer point the receiving plate is so arranged that the shells are permitted to roll on to the second conveyor so that they will rest in the same relative position as they did on the first conveyor. This practice was found to be of great assistance to the men removing the shells as they were able to tell at a gance from which press the shell had come, thus aiding in identifying the heat series of the respective forgings. These were then removed from the conveyors by men on either side and arranged in piles or on the floor according to the carbon content contained in the series. A fuller explanation of this will be given later.

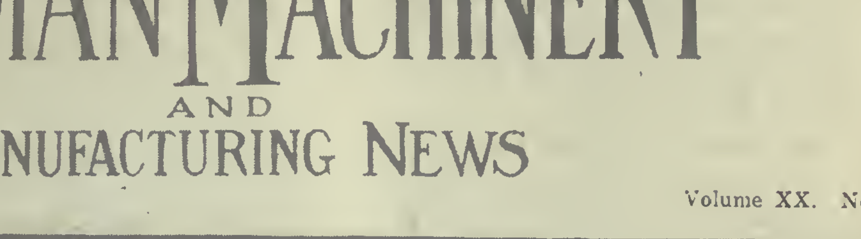

FIG. 2—6-INCH FORGING PUNCH

Furnace Installation

In the forging of the 6 inch shells three furnaces are generally used to supply two presses so that the operations will be continuous. Seven large continuous type furnaces are installed for the heating of the 6 inch billets. Four of these are adapted to take three rows of billets, and have a heating capacity of about 70 per hour. The other furnaces are a little narrower, accommodating two rows of billets and have a capacity of from 35 to 40 per hour. In addition to this installation there are three furnaces, one of which has recently been erected, two of these units have been operating on 75 mm. billets, but will shortly be used both for this shell and the British shrapnel, work on the latter to be started immediately. The furnaces are located in a long row at the rear of the line of presses. All furnaces are oil fired, operating under an oil pressure of 40 pounds, and air pressure of 10 ounces. The average temperature of

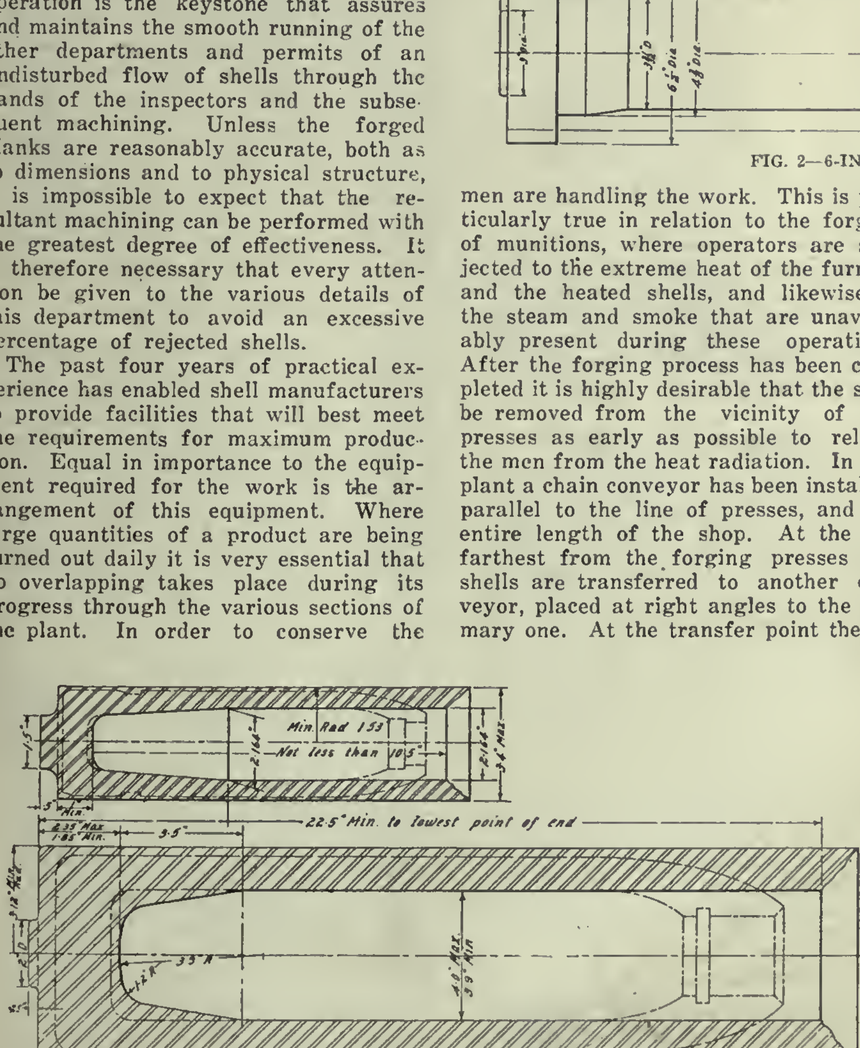

FIG. 1—75-MM. AND 6-INCH SHELL FORGINGS

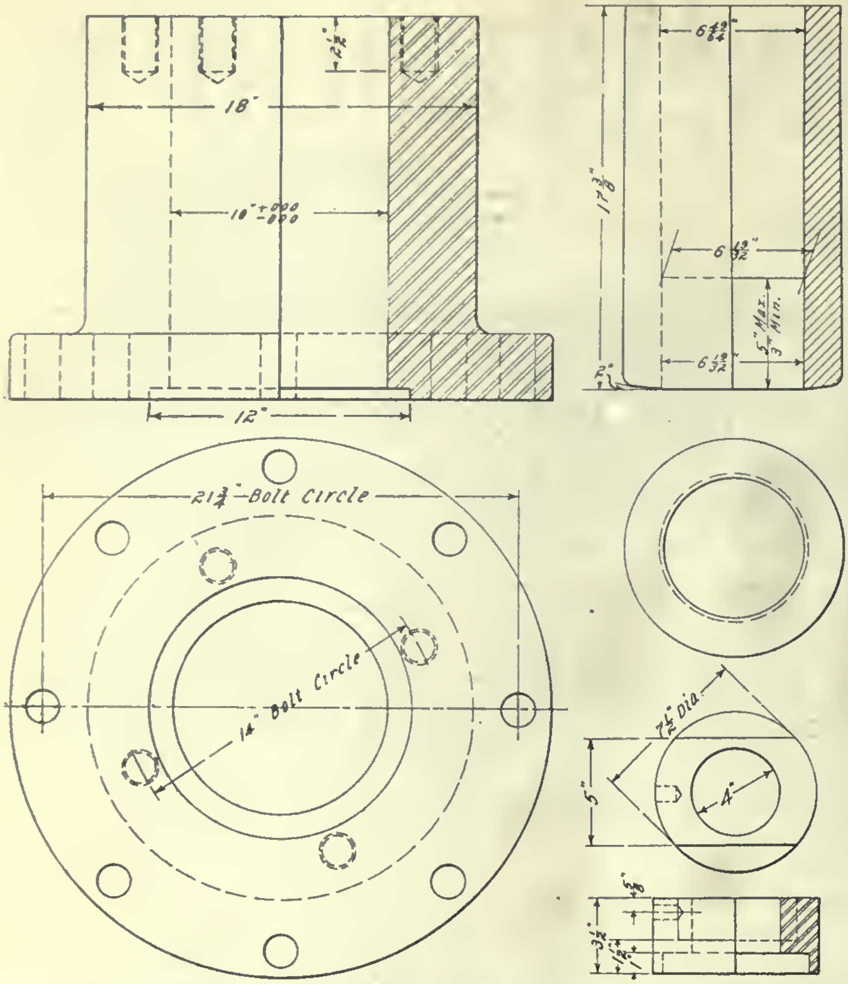

FIG. 3—DIE POT AND BUSHING FOR 6-INCH PRESS

the billets when removed from the furnace is generally between 2000 degrees and 2100 degrees Fahr., but this temperature is frequently regulated to suit the analysis of the steel for each particular heat series.

Square Shaped Billet

The length and inclination of the furnace bottom allows the billets to turn over about six times between the time they are loaded into the furnace and when they are removed at the discharge end. Two types of billets are used at this plant for the production of the 6 inch shell forgings. The round billet, which is the one generally adopted in the majority of forging plants, has a diameter of 6 7-16 inches and an approximate length of 17½ inches, and weighs about 160 pounds. The bulk of the forgings produced at this plant, however, have been made from Gothic steel somewhat square in cross section, with rounded corners and the sides with a slight convex contour. The measurement across the corners is practically the same as the diameter of the round billet but the length is about 21½ inches. In forging from the round billet the metal flows in a vertical direction, but in the case of the square shaped billet the metal is forced sideways to fill up the round die, the upward extrusion being very little, as the average length of the forging is about 22½ inches. It is claimed that these shapes are easier to produce at the mills and also that the presses are less taxed in producing the forgings. Owing to the action of the metal however, there is a slight possibility that the steel would be less dense at those portions of the finished forging formed from the sides of the square-shaped billet.

Forging the 6-inch Shell

In the lower part of Fig. 1 is shown a longitudinal section of a 6-inch forging, with the outline of a finished shell shown in dotted lines. Three 500-ton Southwark hydraulic presses are installed for the 6-inch operations, the normal production being about 50 shells per hour from each press. The punch platten carries two punches in a turret, but only one is in operation at a time, it being located in a central position when forging a shell. Each punch is used alternately, and at each operation the one not in use enters a well of water, kept cool by circulation. This method eliminates the need of the ring cooler generally adopted for this purpose. A sketch of the 6-inch forging punch is illustrated in Fig. 2. These punches are not screwed into the turret but are held in position by means of a binder ring. To aid the punch in entering the center of the billet a centering ring is placed on the top of the billet so that the punch is prevented from crowding to one side, should it show a tendency to do so. A sketch of this ring is shown in the lower right of Fig. 3. The other views are those of the die pot and the die pot bushing. The latter is the renewable piece and is made of chilled cast iron, with an overall length of 17⅝ inches. The hole is tapered from 6 49-64 inches at the top to 6 19-32 inches about four inches from the base, the remaining portion being parallel. Three bushings are held in position by shrinking on the die pot. The forging is produced at one stroke of the press, the shell being stripped from the punch by means of a stripper operating in a slide at the top of the die pot. The shell is ejected by means of a hydraulic kicker.

Conveyor System

To assist in keeping the heat series separate the forged shell from one press are located on the conveyor with the base forward and those from the other press with the open end forward. When the moving shells reach the point where they are removed for cooling this system affords an easy means of identifying the press from which the shells have been produced. A feature of these conveyors is the roller arrangement working in conjunction with the primary chain. The latter is operated by a 15 h.p. motor and travels at a speed of about 100 feet per minute, but the concave rollers, connected by the links of the chain and rolling on the supporting channels, cause the shells to travel at a speed almost double that of the conveyor. The great advantage of this method is that the hot shell never rests in the one spot, so that overheating of the chain or rollers is eliminated. In chain conveyors where this principle is not incorporated trouble has frequently been caused by the slight stretch resulting from the hot shell resting too long a period in the one position.

Primary Cooling

On either side of the second conveyor considerable space is provided for the cooling or piling of the forgings. This cooling process is quite interesting, inasmuch as each series is treated differently according to the initial analysis of the steel and the heating of the billet prior to the forging operation. The specifications call for a steel giving a yield of 19 tons or over, a breaking stress of 50 to 55 tons, and an elongation of 15 per cent. or over. The carbon content should be between .40 and .60 and the manganese between .60 and 1.00 per cent. A steel may be relatively low in carbon and yet sufficiently high in manganese to meet the requirements of the specifications. The constant—230—found by multiplying the carbon content by 3 and adding the percentage of manganese—has been found to be a good guide for subsequent heat treatment. Thus a steel of .52 carbon and .74 manganese will give results of a highly satisfactory character under normal treatment. In general, steels that show a value higher than 230 require a slow cooling process, and those below this should be cooled quickly, the process being modified to conform to specific conditions. For rapid cooling the shells are placed on end on the floor.

so that the heat radiated from the shells will be absorbed by the atmosphere as quickly as possible. This treatment will range from extreme separation of the forgings for low value to close packing under a steel hood for high carbon steels.

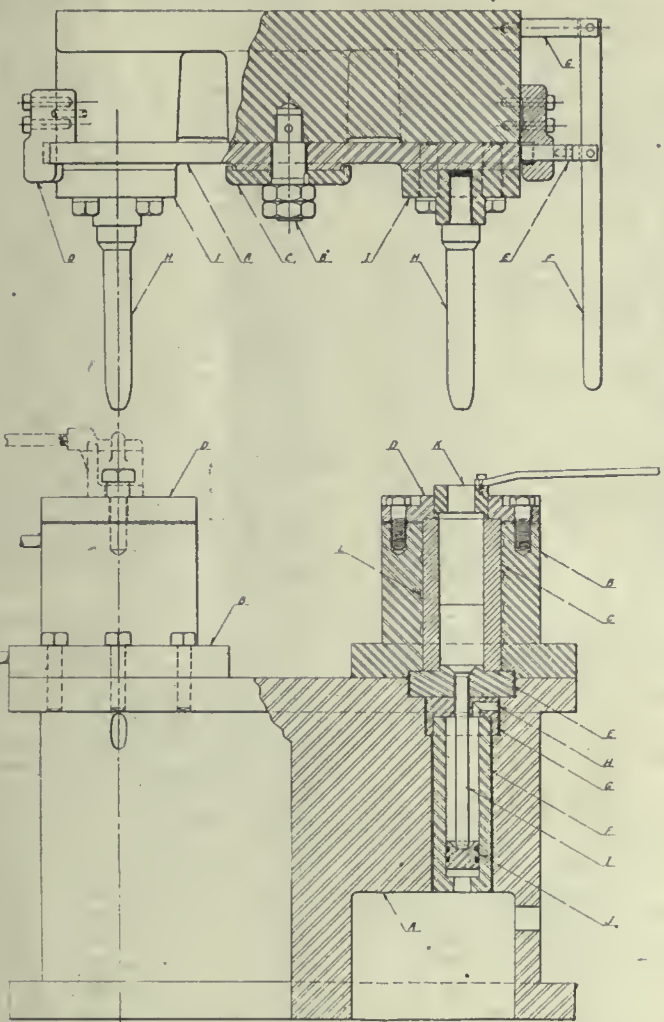

FIG. 4—ASSEMBLY OF TOOLING FOR FIRST FORGING OPERATION.

Special Cooling Apparatus

Additional treatment is frequently required where the original cooling system is not sufficient to meet the end desired. This normalizing process may mean either of two things—shells in which the steel is too soft, requiring to be hardened, or those that are too hard requiring to be annealed. For the former process an elaborate cooling system has been installed which is proving very efficient. For treatment in the oil-fired furnaces the shells are placed on special steel trucks, and so arranged that the heat is evenly distributed to the entire surface of every shell. When loaded to capacity, or the total of that particular heat series, the trucks are drawn into the furnace chamber and the ends closed. After the forgings have been raised to a temperature of approximately 1,500° Fahr. they are removed in lots of eight, which is the capacity of the cooling apparatus. It might be said that these furnaces are practically continuous as the loaded trucks are gradually drawn into the furnace as the heated shells are removed, others being loaded at the opposite end.

The cooling device is so designed that the air is forced against the base, or heaviest portion of the shell; this action takes place simultaneously inside and out, so that the cooling of the entire shell is very uniform. The shell is placed on a hollow mandrel and then shoved into a larger pipe, after which the blast is turned on, the air being delivered to the exterior and interior at the same time. Eight minutes is the average time required to cool the forgings from 1,500 degrees to about 850 degrees, when they are removed and allowed to cool in the usual manner by placing in piles.

Annealing Hard Shells

Reverse treatment is required when the shells show extreme hardness. In this case annealing is essential. The shells are placed in batches on trucks and drawn into the furnace where the temperature is raised to the critical stage, and allowed to soak for a period, after which they are allowed to cool to a lower temperature and then removed from the furnace and placed under cover for slow cooling. The annealing period is generally regulated to suit the analysis of the steel. The treatment of a specific case may serve for illustration. The analysis of a certain steel showed .62 carbon and .92 manganese. This figured out at 48 points above the normal constant 230. A batch of 87 of these shells were placed in the furnace and raised from 650° Fahr. to 1,550° Fahr. in 2 hours and 20 minutes. They were allowed to soak at 1,550° for a period of 2½ hours, then the burners were shut off and the shells allowed to cool to a temperature of about 650°. The loaded truck was then removed and hoods placed over the shells to prevent rapid radiation.

This installation has been of inestimable service in turning out a highly uniform product. The plant is not only used for treating their own product but the capacity is ample to meet the needs of other forge shops.

Cutting Off 75 mm. Billets

The billets for the 75 mm. forgings are obtained from 3⅝ inch round bars, averaging 10 feet in length. The method of cutting these bars into billet lengths, together with the spacing device, is of

FIG. 5—PIERCING AND DRAWING PUNCHES FOR 75MM. FORGINGS.

special interest. As in the case of the heavier shells, every facility is provided to minimize all unnecessary physical effort that would tend to sap the energy of the workmen. Railways and gravity conveyors are installed to carry the bars from the rollway cars to the machines. The spacing machine for gauging the length of the billets was designed by Mr. Beck, the superintendent of the heat-treating department of the Cluff Munitions Co. Previous to the introduction of this device the division of the bars was more or less a matter of guesswork, considerable scrap accumulating from the waste end of each bar. With the new device the bars can be so cut that no waste is evident, the surplus metal being distributed equally among the 12 billets in the average bar. The principle of the design is that of the pantograph, the lattice work being located beneath a long channel iron that forms the frame of the machine; upon the upper surface of this channel is arranged the evenly spaced pieces of angle iron. These are connected to the center pivots of the pantograph by means of machined bolts, latteral travel being provided for by a slot cut through the center of the channel iron. To ensure equal spacing of the gauging surfaces, the network of links is operated from equidistant points, these in turn being operated from and connected to a central lever by means of various length links. The central lever is directly connected to the control lever which is located at one end of the machine.

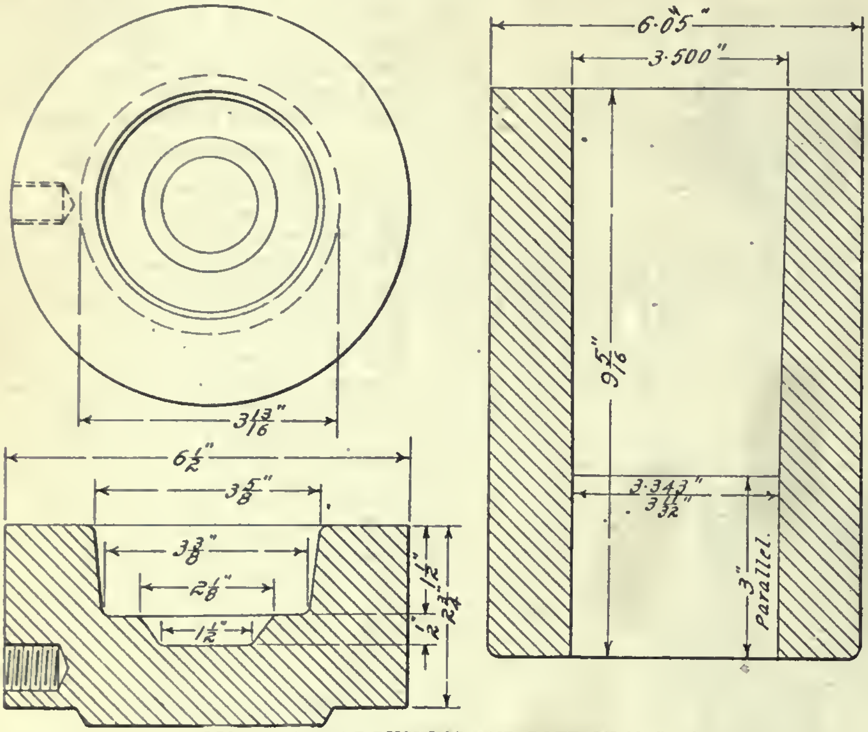

FIG. 6—DIE POT BUSHING AND BOTTOMING PAN

When a bar is placed in position with one end against the initial stop, and it is found that the other end lies between two gauging points, the control lever is moved one way or the other to bring the end in line with the nearest gauging point. Thus, suppose the bar to be 10 feet 3 inches in length and the normal length of a billet to be 10 inches, the usual practice would provide 12 billets with 3 inches of scrap. With the new device this 3 inches can be distributed among the 12 billets, making each 10¼ inches long. When the bar is placed in position, with one end against the forward gauge, the operator with the oxy-acetylene torch commences to nick the bar, the spacing being adjusted by the operator on the other end. The initial gauge is always in a fixed position and is located at the opposite end to the control handle. Any movement of this handle operates the entire pantograph so that the space between each gauge will close or separate an equal amount, but the gauging point farthest from the stationary gauge will travel a distance —one way or the other—equal to the spacing adjustment multiplied by the number of spaces. This adjustment is only a matter of a couple of seconds so that the nicking operator can move from one gauge to the next without troubling about the length of the billets.

After the bars have been nicked with the torch they are rolled down a slight incline to the large geared punch press, where the bars are broken into lengths. The nicked portion is kept at the bottom while the bar is moved beneath the wedge point of the punch. When care is exercised in keeping the nick in a central position a clean square break is invariably obtained. The billets are then placed on a conveyor adjoining the press and carried for about 150 feet to the space reserved at the rear of the furnaces. With the exception of the handling of the billets or forgings at the various machines or furnaces no manual labor is required, as the movement from one operation to the next is performed by the conveyors.

Forging 75 mm. Shells

The heating of the 75 mm. billets is accomplished on the same principle as the larger shells but the furnaces have a capacity for 250 billets. For the forging operations four Southwark presses are installed, two of 350 tons and two of 210 tons capacity. At present one of each is working on the 75 mm., the other two to be utilized for the British shrapnel when work on these shells is under way. The larger of these presses are adapted for the piercing operations and the smaller for the subsequent drawing process. The general practice on these small shells is to forge two at the same time, transferring the pierced billets to the drawing press, so that the complete

SPACING MACHINE DESIGNED BY MR. BECK.

forging operation is accomplished at the one heat.

The details of the mechanism necessary for the primary piercing operation is illustrated in Fig. 4, half of which is shown in section, both sides being identical. The pedestal A is secured to the bed of the press, and carries on the upper surface the die pots B, in which is contained the renewable chilled cast iron bushing C. Located at the bottom of this bushing is the cast steel piece E that shapes the tit on the base of the forging, together with any lettering that may be required for identification purposes. Located in the body of the pedestal is the bushing F, held in position by the collar G, through which is the channel H for the lowering of the plunger J. The kicker pin I is operated by this plunger which travels vertically in the cylinder F. With the die pot B firmly bolted to the pedestal the entire central works are held in position by the binder ring D. Through this binder ring there is a hole—centrally located—to take the centering ring K, the bore of the latter being a sliding fit for the piercing punch, and guiding the latter when in operation. For keeping the

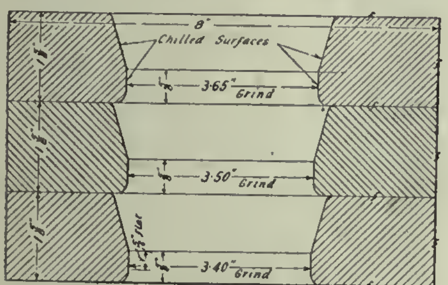

FIG. 8—CHILLED CAST IRON DRAW RINGS.

bushing cool a spiral groove L is cut in the die pot, and through this groove water is kept circulating, so that little trouble is ever experienced by the overheating of the dies.

On the movable ram of the press the turret A is held in position by means of the washer C and the bolt B, bearing brackets D being provided to support the outer edges. If sufficient lift is given to the ram the turret need not be used, but it is frequently found more economical to regulate the stroke of the press and swing the punches clear while removing the forgings. When in a central position the turret is locked by the stop pin E, which is operated by the handle F. The piercing punch H is screwed into and held in position by the binder ring I. Both billets are pierced simultaneously, and when removed from the dies are given to the operators on the drawing press for the final process of drawing to length and sizing the outer diameter.

A sketch of the piercing punch and the details of the nose is shown at the top of Fig. 5. The overall length of the working portion is 12 inches and the diameter of the main section is 2.18 inches, with the exception of the 2¾ inches at the end, this portion being tapered from the body of the punch to a diameter of 1 13-16 inches, the radius of the nose being ¾ inch; the center for a diameter of 5-16 inch having a radius of 2¾ inches. The dimensions of the die pot bushing can be seen in the sketch Fig. 6.

Draw Press Details

The details of the drawing press is shown in Fig. 7. The top plate A that carries the punch holders or adapters C, is bolted to the ram of the press. The upper end of the adapters is provided with a collar and is held in position by means of the binder ring B. The draw punch E is screwed into the holder. The ring and the chills being supported on the steel plate L. When the pierced blanks are first brought to the draw press the base is formed by using the bottoming pan, after which the pan is removed and the blank shoved through the three dies and stripped from the punch by inserting the stripper O.

The sketch of the draw punch and nose dimensions is shown in the lower part of Fig. 5. The wall of the forgings is reduced gradually as it passes through the three cast iron chills, the

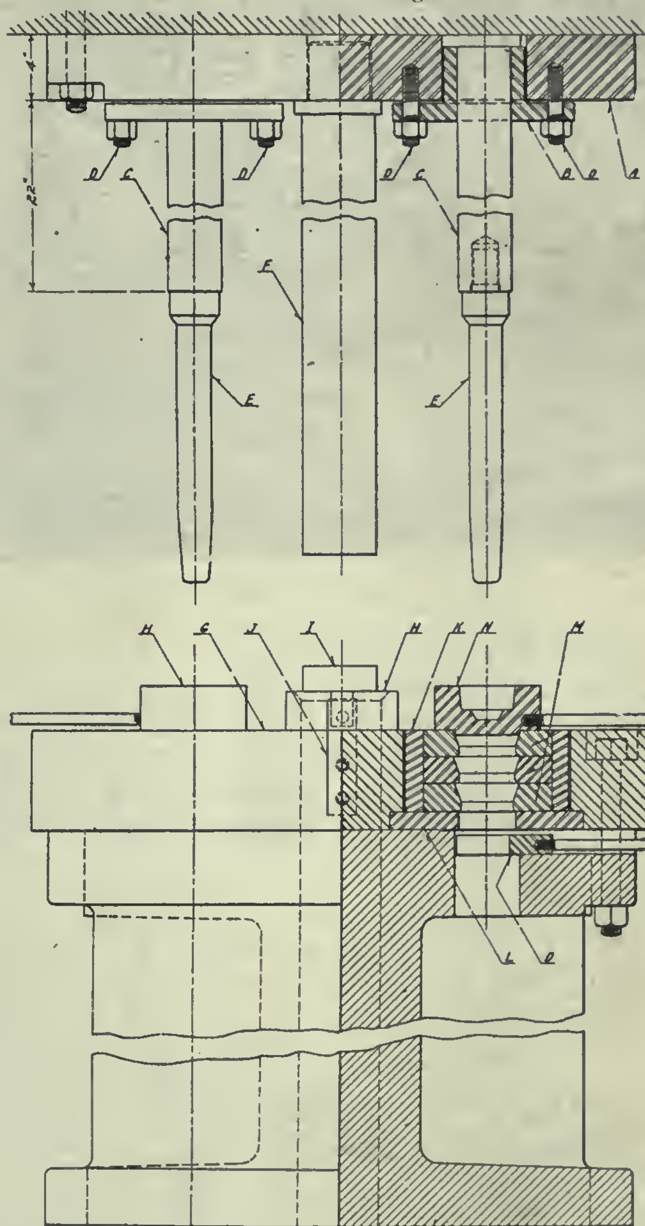

FIG. 7—ASSEMBLY OF TOOLING FOR DRAWING OPERATION.

posts F, one on either side, are used as stops when forming the tit on the end of the forging, and also act as guides when drawing the shells. On the top of the pedestal is secured the plate G that carries the draw rings. When forming the base on the forging the draw plate H with the stop I is moved into position below the posts on the ram, so that the thickness on all the forgings will be the same when the bottoming pan N is resting on the top of the draw rings, as shown in the sketch. The three chills M are held in the retainer ring K, this first reduction being to a diameter of 3.65 inches, the next to a diameter of 3.5 inches, and the final draw leaving the outside diameter 3.4 inches. This gives a wall thickness on the forgings of approximately .612 inch. The general appearance and dimensions of a finished forging are illustrated in the upper half of Fig. 1.

The treatment of the 75 mm. shells after forging is conducted along the same lines as that adopted for the 6 inch forgings, the requirements being practically the same in every respect.

ENGLISH MUNITION JIB CRANE

By P. E. R.

THE electrically operated 4-cwt. jib crane, used in shell factories, as developed by Royce, Limtied, of Trafford Park, Manchester, England, noted in the accompanying illustration, is crane consists of a couple of stout mild steel channels, to which the steel lattice jib of the crane is attached, the mast and the jib being carried on the centre post by two roller bearings, with a suitable top bearing to take the weight. The load is lifted on a single fall of steel

ENGLISH JIB CRANE FOR SHOP USE.

a light type of high speed travelling hoist of recent design.

This crane has the hoisting motion and travelling motion electrically driven, whilst slewing is carried out by hand by pushing or pulling the load. The crane runs on a narrow gauge track, centres of rails being 3 ft. 6 in. and is arranged to pick up current from bare conductors placed in conduit in the centre of the track.

The crane illustrated deals with a 6-cwt. load at a radius of 12 ft. 6 in., the height of jib head pulley being approximately 10 ft. 0 in. above rails. The hoisting speed is approximately 25 feet per minute, while the travelling speed is about 300 ft. per minute and has a factor of 2 to 1 against tipping

It will be observed that the operator's cage or platform is attached to one end of the baseplate and the whole of the control gear, consisting of controllers, resistances, D. P. emergency switch and fuses, is mounted in a convenient position. The hoisting motion is driven by a totally enclosed series wound reversing motor, fitted with a solenoid brake and driving a cast iron machined grooved barrel through machine cut gearing.

The travelling motion is operated by a "Royce" enclosed series wound reversing motor, driving through machine cut gears on to one axle and the two axles being coupled together by means of a Hans-Renold chain. The baseplate of the crane is a massive iron casting, carrying the travelling axle bearings and the centre post of the crane. The mast of the wire rope and the hook is of the swivelling type.

The travelling wheels are of steel, of the single flanged pattern of large diameter, turned on the tread, while the travelling axles are carried in easily renewable brass-bush bearings and the travelling axle nearest the driver's platform is fitted with a powerful brake, operated by means of a foot lever.

PROBLEMS OF MACHINE CONSTRUCTION

By T. H.

Some few weeks ago a paper was read before the American Society of Mechanical Engineers on the subject of "Aeroplane Engine Design." The paper has attracted a good deal of attention in this country by reason both of its acute analysis of the aeroplane engine problem and its extremely well-informed and practical treatment of the subject. But there is another striking feature of the paper which has hardly been commented upon. It deals in a way most unusual in technical papers with the practical mechanical problems that arise in the designing and building of all mechanisms. One example will suffice to show what it meant. The author, Mr. G. E. Lucke, having described the advance from the side-pocket arrangement for the cylinder valves to the valve-in-the-head arrangement, with the advantages accruing from the latter, passes to a consideration of the replacement of the cast iron jacket wall, which has no other function than to hold water, by some lighter arrangement. No sooner is the problem faced than a structural difficulty is at once apparent—the necessity of providing openings for the intake or outlet from each valve, an igniter plug hole, and at least two pipe connections for each jacket, and seatings for certain driving gear fastenings. This, naturally tends towards the retention of a casting as one part of any improved arrangement, and the next step, which though logical enough, took several years to make, was to have the cylinders of cast iron, the head and head jacket in a one-piece casting, and sheet metal for the jacket over the cylinder barrel. Proceeding further along the same line of weight reduction the next step is to cut away this cast iron joining the ends of the parts forming the wall of the head jacket and substituting sheet metal welded to the parts by the oxygen flame, brazing or welding on any additional supports for the attachment of gears. When this is done the cast iron cylinder is still there with its cast iron parts, and there is a fundamental objection to a cast iron cylinder for aeronautical work. Cast iron cylinders need not be very thick to stand the gas pressure stresses provided the metal can be relied upon, but no one can be absolutely sure that the metal inside is good and the use of cast iron cut down to one-eighth inch thick incurs taking chances, hence attention is turned towards steel. Drawn steel or forged steel is reliable, and should be just the material required, but when one comes to study how to use a drawn steel tube for a cylinder and how to get the necessary attachments on it the matter proves not at all simple. That is why the adoption of the steel cylinder was so long delayed. There are now, however several methods of making steel cylinders. There is the steel tube screwed into a separate cast iron head carrying the ports and head jacket cast in one piece; there is an all steel cylinder in which a steel cylinder head is welded to a steel tube body; there is the cylinder made in the form of a drawn-steel shell with head like a cartridge case; there is the Hispano-Suisa arrangement, in which the entire outside of the cylinder is thread and the cylinders are screwed into an aluminum casting which is double-walled just like the cast iron block casting in an automobile engine, and there is finally the one-piece steel forging construction for cylinder, cylinder-head, ports, and ignition holes, surrounded by a steel metal welded jacket. Mr. Lucke discusses the pros and cons of all these arrangements from exactly that standpoint for which the inventor-designer-mechanic may search.

An alloy said to be suitable for springs or polished sheets has been patented by C. L. Jones. The alloy consists of copper, 28 per cent.; nickel, 67.8 per cent.; manganese, 2.5 per cent.; iron, 1.5 per cent., and vanadium, 0.2 per cent.

Metal Workers Will Gather in Milwaukee Oct. 7

Several Association Are Holding Big Gathering, When Matters of Importance Will be Considered—Exhibition of All Sorts of Labor-saving Machinery For Metal Working Will be a Feature

AT Milwaukee, during the week of October 7, will be held the greatest gathering of metal manufacturers ever assembled in this or any other country. Simultaneous meetings will be held by the American Foundrymen's Association, Iron and Steel section of the American Institute of Mining Engineers, Institute of Metals division of the American Institute of Mining Engineers, and American Malleable Castings Association. Concurrent with these meetings will be conducted an exhibition of all kinds of labor saving metal working equipment. Every branch of the metal industries will be represented, including the gray iron, steel, malleable iron and brass foundry trade; iron and steel industry, from the mining of the ore to the production of pig iron, its conversion into steel and finally the rolled product and the brass and copper mill rolling industry.

The keynote of many of the addresses and papers that will be presented will be the acceleration of production for the prosecution and winning of the war. In fact, the purpose underlying the holding of this great meeting is to afford manufacturers of ordnance and other war equipment an opportunity for an interchange of ideas regarding methods of production and operation.

The great interest that is being manifested in this event is reflected by the large number of reservations for space in the Milwaukee Auditorium, where the exhibition will be held. Already 165 manufacturers have decided to make displays and only a comparatively small amount of space is still available. The indications are that this will be the largest show of its kind ever held in this country.

The manufacturers of Milwaukee already have organized committees on arrangements for the entertainment and reception of the visitors who will number from 3,500 to 4,000. The program, although not definitely outlined, will include a reception and dance at the Milwaukee Auditorium, theater party and boat ride. In addition the visiting ladies will be taken on an automobile sightseeing tour and will be tendered several luncheons. Plant visitation probably will be confined to Thursday and Friday and many notable works in the Milwaukee district will be open for inspection. On Thursday evening, Oct. 10, the banquet will be held and addresses will be delivered by speakers of international fame. The Milwaukee committees on arrangements are constituted as follows:

General Committee

Theo. O. Vilter, chairman, president, Vilter Mfg. Co.; W. J. Fairbairn, secretary, Milwaukee Metal Trades and Founders' Association; A. Harrison, superintendent foundry and pattern shop, Allis-Chalmers Mfg. Co.; E. Bearman, Illinois Steel Co.; John D. Bird, general manager, Power & Mining Machinery Co., Cudahy, Wis.; James Marshall, general manager, Geo. H. Smith Steel Castings Co.; W. G. Bruce, secretary, Milwaukee Association of Commerce; Henry Weber, chairman, Milwaukee park board; Geo. Kuemmerlein, superintendent of transportation, Milwaukee Electric Railway & Light Co.; A. E. Copeland, manager, Hotel Wisconsin; W. P. O'Connor, general agent, Goodrich Transportation Co.; F. C. Reynolds, general agent, Pere Marquette railroad, and Jos. C. Grieb, manager, Milwaukee auditorium.

Finance Committee

Theo. O. Vilter, chairman, Vilter Mfg. Co.; W. G. Bruce, Milwaukee Association of Commerce; C. R. Messinger, Chain Belt Co.; J. D. Bird, Power & Mining Machinery Co., Cudahy, Wis.; T. A. Glasscott, Pickands, Brown & Co.; John Thomas, Thomas Furnace Co.; A. J. Lindeman, Lindeman & Hoverson Co.; Otto H. Falk, Allis-Chalmers Mfg. Co., and Walter Kasten, treasurer, finance committee, Wisconsin National Bank.

Entertainment Committee

Geo. Kuemmerlein, chairman, Milwaukee Electric Railway & Light Co.; Henry Weber, Milwaukee park board; J. J. McDevitt, S. Obermayer Co.; John Mertes, Federal Foundry Supply Co.; C. E. Lemmon, chemist; T. A. Glasscott, Pickands, Brown & Co.; James Marshall, Geo. H. Smith Steel Castings Co.; F. C. Reynolds, Pere Marquette railroad, and J. S. Pinson, Avery Co.

Golf Committee

J. D. Bird, chairman, Power & Mining Machinery Co., Cudahy, Wis.; C. R. Messinger, Chain Belt Co.; David McLain, McLain's System; F. E. Layman, chemist, and C. G. Ocock, Avery Co.

Reception Committee

E. Bearman, chairman, Illinois Steel Co.; Frank Cleveland, Milwaukee Association of Commerce; David McLain, McLain's System; J. D. Shaw, Shaw Foundry Co.; E. A. Wurcester, Falk Co.; J. A. McDevitt, S. Obermayer Co.; Henry R. Donald, Essley Machinery Co.; T. A. Glasscott, Pickands, Brown & Co.; O. B. Puplkofer, American Gum Products Co.; W. J. Fairbairn, Milwaukee Metal Trades & Founders' association; Roy Smith, Hotel Pfister; A. E. Copeland, Hotel Wisconsin; Henry Wehr, Wehr Steel Castings Co.; Herman Kletzsch, Republican House; W. W. Sommers, Hotel Carlton; W. M. Nefzger, Hotel

THE AUDITORIUM AT MILWAUKEE WHERE THE CONVENTION OF THE AMERICAN FOUNDRYMEN'S ASSOCIATION AND THE AMERICAN INSTITUTE OF METALS WILL BE HELD DURING THE WEEK OF OCT. 7, 1918.

Schiltz; S. Duffy, Hotel Plankinton, and F. B. Sweeney, Hotel Maryland.

Plant Visitation Committee

A. Harrison, chairman, Allis-Chalmers Mfg. Co.; James Marshall, Geo. H. Smith Steel Casting Co.; H. R. Donald, Essley Machinery Co.; Wells K. Greg and H.G. Siefert.

Banquet Committee

W. P. O'Connor, chairman, Goodrich Transportation Co.; A. E. Copeland, Hotel Wisconsin, and H. Weber, Milwaukee Park Board.

Theatre, Automobile and Boat Excursion Committee

James Marshall, chairman, Geo. H. Smith Steel Casting Co., and J. C. McDevitt, S. Obermayer Co.

Ladies' Committee

E. E. Copeland, chairman, Hotel Wisconsin; F. C. Reynolds, Pere Marquette railroad; Henry Weber, Milwaukee park board and O. B. Puplkofer, American Gum Products Co.

CITY HALL, MILWAUKEE.

GRAND AVE., LOOKING EAST.

The meetings of the Allied Metal Trades Association will be opened on Tuesday morning, Oct. 8, with a joint session at which the address of welcome will be delivered by Emanuel L. Phillip, governor of Wisconsin. This will be followed by addresses relating to the importance of the metal working industry in the prosecution of the war by speakers of note who are familiar with the activities at Washington. Upon adjournment, the opening session of the American Foundrymen's Association, Iron and Steel section, and the Institute of Metals division of the American Institute of Mining Engineers will be called to order in separate halls in the Milwaukee Auditorium where the activities of the week will be centered.

Will Use Moving Pictures

The exhibition will be opened formally on Monday afternoon, Oct. 7. Beginning Tuesday, Oct. 8, the American Foundrymen's Association will hold daily meetings in the morning only, and on several days simultaneous sessions will be necessary to dispose of the lengthy program in time for adjournment Friday noon, Oct. 11. The Institute of Metals division of the American Institute of Mining Engineers will have one meeting on Tuesday, two on Wednesday, and one on Thursday. The Iron and Steel section of the American Institute of Mining Engineers will hold three meetings and will adjourn Wednesday afternoon. Only one meeting is scheduled by the American Malleable Castings Association.

One of the notable features of these meetings will be the large number of interesting moving pictures that will be shown. These will include the use and manufacture of hand grenades; the civil re-establishment of wounded and crippled Canadian soldiers; the manufacture and launching of ships at the Hog Island yard, Philadelphia; the building of concrete ships; the manufacture of steel by the triplex process, and the cause and prevention of industrial accidents.

The program of the American Foundrymen's Association includes a large number of papers of interest to manufacturers of gray iron, steel and malleable castings. To dispose of the program in the time alloted, separate sessions will be held for the consideration of papers relating to gray iron, steel and malleable iron foundry practice. An accident prevention conference also is scheduled at which a large number of papers will be presented and addresses delivered on the conservation of life and limb in industrial plants.

The Program of Events

A tentative program of the topics that will be discussed follows:

"Sand-Blasting Equipment," by C. T. Bird, Pangborn Corp., Hagerstown, Md.

"Engineers—Their Relation to the Foundry in the Saving of Labor," by E. S. Carman, Cleveland Osborn Mfg. Co., Cleveland.

"Pouring Devices," by Mark P. Ohlsen, Brillion Iron Works, Brillion, Wis.

"Effective Means of Improving the Quality of Sand Mixtures," by H. B. Hanley, New London Ship & Engine Co., Groton, Conn.

"Common Troubles in Cupola Practice Which Tend to Cut Down Production," by G. S. Fisher, Whiting Foundry Equipment Co., Harvey, Ill.

"Women in Foundries," by C. E. Knoeppel, C. E. Knoeppel & Co., New York.

"Organizing a Foundry for Tractor Production," by Paul M. Ramp, Moline, Ill.

"Coke Problems of the Foundryman," by J. A. Galligan, Pickands, Brown & Co., Chicago.

"Recent Developments in Burning Oil in Cupolas," by John Howe Hall, Taylor-Wharton Iron & Steel Co., High Bridge, N.J.

"Continuous Operation of a Two-Storey Foundry," by J. F. Ervin, Michigan Motor Castings Co., Flint, Mich.

"Sale and Distribution of Foundry Pig Iron in War Times," by C. J. Stark, editor the "Iron Trade Review," Cleveland.

"Concrete Foundry Floors," by George Moyer, Textile Machine Works, Reading, Pa.

"Training Your Own Help Instead of Competing With Other Manufacturers," by Ernest Van Billiard and T. Hough, Jr., General Railway Signal Co., Rochester, N.Y.

"Blowers," by J. Trinks, Pittsburgh.

"Precipitation of Dust in Foundries," by H. D. Egbut, Research Corp., New York.

"Pyrometers and Their Application to Core Ovens," by J. P. Goheen, Brown Instrument Co., Philadelphia.

"Cast Iron in Service Projectiles and Trench Warfare," by Major Edgar Allen Custer, Pittsburgh district ordnance department, Pittsburgh.

Moving picture film on the "Manufacture and

Use of Hand Grenades," by Major Frank B. Gilbreth, Providence, R.I.

"A Rapid Method for the Determination of Graphitic Carbon," by Frank H. Kingdom, Metallurgist, Sullivan Machinery Co., Claremont, N.J.

"Cores in the Foundry," by Walter F. Prince, Elizabeth, N.J.

Malleable Iron Foundry Practice

"Some Features of Malleable Iron Practice," by J. G. Garrard, Northwestern Malleable Iron Co., Milwaukee.

"Soundness," by Enrique Touceda, Albany, N.Y.

"Annealing Malleable Iron," by H. E. Diller, General Electric Co., Erie, Pa.

"Use of Malleable Castings," by H. A. Schwartz, National Malleable Castings Co., Indianapolis.

"White Rim or Picture Frame Fractures," by J. B. Deisher, T. H. Symington Co., Rochester, N.Y.

"Advantages of Malleable Iron versus Steel for Agricultural Castings," by W. A. Forbes, Rockford Malleable Iron Co., Rockford, Ill.

"The Symington Core Department," by Donald S. Barrows, T. H. Symmington Co., Rochester, N.Y.

Accident Prevention Conference

"The Cause and Prevention of Industrial Accidents," to be shown by moving pictures and illustrating accidents as reported to the Industrial commission of Ohio.

"Accident Prevention is Good Business," by Hon. Fred M. Wilcox, vice-president Wisconsin industrial commission.

"What the State Can Do to Prevent Accidents," by Hon. Thomas J. Duffy, chairman, Industrial commission of Ohio.

"What the Buckeye Steel Castings Co. Has Accomplished in Accident Prevention," by Fred G. Bennett, safety director, Buckeye Steel Castings Co., Columbus, O.

"The Importance of Organization in Accident Prevention," by C. W. Price, field secretary, National safety council, Chicago.

"The Vital Necessity of Conserving Man Power During the War," by Victor T. Noonan, safety director, Industrial Commission of Ohio, Columbus, O.

"What Shall be Done with the Crippled Soldier," by W. A. Janssen, vice-president, Canadian Steel Foundries, Montreal, Canada.

Steel Foundry Practice

"Ordnance Steel for the Army and Navy," by John Howe Hall, Taylor Wharton Iron & Steel Co., High Bridge, N.J.

"Operating an Electric Furnace for the Production of Ordnance Castings," by W. E. Moore, Union Bank building, Pittsburgh.

"Steel Foundry Practice in the Far West," by J. D. Fenstermacher, Columbia Steel Co., San Francisco.

"Acid versus Basic Lining for Electric Furnaces," by F. J. Ryan, Electric Furnace Construction Co., Philadelphia.

An interesting report on the heat treatment of steels Nos. 2 and 3, specified by the ordnance departments also will be submitted. This will be followed by a topical discussion of the manufacture of steel for ordnance purposes by foundrymen who have had a wide experience in this work.

The program of the Institute of Metals division of the American Institute of Mining Engineers is replete with practical topics of interest to the brass foundryman. One feature of this gathering will be the discussion of the conservation of tin and representatives of various industries using tin in manufacture will contribute to this symposium.

Tuesday Morning, Oct. 8

"The Metallography of Tungsten," by Zay Jeffries.

"The Constitution of the Tin Bronzes," by S. L. Hoyt.

"Notes on Babbitt and Babbitted Bearings," by Jesse L. Jones.

"Oxygen and Sulphur in the Melting of Copper Cathodes," by S. Skowrouski.

"The Relation of Sulphur to the Overpoling of Copper," by S. Skowrouski, with discussion by Philip L. Gill.

Wednesday Morning, Oct. 9

Symposium on "The Conservation of Tin." This topic will be discussed by the following:

G. W. Thompson, National Lead Co.
G. H. Clamer, Ajax Metal Co., Philadelphia.
C. M. Waring, Pennsylvania Railroad Co.
M. L. Lissberger, Mark Lissberger & Son, Inc., Long Island City, N.Y.
D. M. Buck, American Sheet & Tin Plate Co., Pittsburgh.
W. M. Corse, Buffalo.
G. K. Burgess and Mr. Woodward, United States bureau of standards, Washington, D.C.
M. L. Dizer, war industries board, Washington, D.C.

The first session of the iron and steel section of the American Institute of Mining Engineers will be devoted to the consideration of papers on iron and steel topics. This will include the consideration of iron ores, ferro alloys, silica brick and the manufacture of steel. Another meeting will consider coal and coke. The program tentatively outlined follows:

SESSION ON IRON AND STEEL

Tuesday Morning, Oct. 8

"The Limonite Deposits of Mayaguez Mesa, Porto Rico," by C. R. Fettke and Bela Hubbard.

"The Manufacture of Ferro-Alloys in the Electric Furnace," by R. M. Keeney.

"The Manufacture of Silica Brick," by H. Le Chatelier and B. Bogitch.

"Notes on Some Iron Ore Resources of the World."

"Recent Geologic Developments on the Mesabi Iron Range," discussion by Anson A. Betts and J. F. Wolff.

"A Volute Ageing Break," by Henry M. Howe.

Moving Pictures of the Triplex Steel Process.

SESSION ON COAL AND COKE

Wednesday Morning, Oct. 9

"The By-product Coke Oven and Its Products," by W. H. Blauvelt.

"The Use of Coal in Pulverized Form," by H. R. Collins.

"Carbocoal," by C. T. Malcolmson.

"Low-tempered Distillation of Illinois and Indiana Coals," by G. W. Traer.

"Price Fixing of Bituminous Coal by the United States Fuel Administration," by R. V. Norris and others.

MISCELLANEOUS SUBJECTS

Wednesday Afternoon, Oct. 9

Moving pictures showing the construction of concrete ships.

Moving pictures showing the civil re-establishment of crippled soldiers in Canada.

The exhibition of all kinds of labor saving equipment to be held in the Milwaukee Auditorium, both in size and number of individual exhibits, probably eclipses anything of its kind ever held. Machinery hall will be converted into a foundry and machine shop since practically all of the equipment to be displayed in this section of the auditorium will be operated. Many new devices will be shown which have been designed and built to facilitate the production of materials for the winning of the war. Exhibits will be made by the following manufacturers:

Abell-Howe Co., Chicago.
Abrasive Co., Philadelphia.
Allis-Chalmers Mfg. Co., Milwaukee.
American Gum Products Co., New York.
American Foundry Equipment Co., Cleveland.
American Kron Scale Co., New York.
E. C. Atkins & Co., Indianapolis.
Arcade Mfg. Co., Freeport, Ill.
Asbury Graphite Mills, Asbury, N.J.
Austin Co., Cleveland.
Ayer, Lord & Tie Co., Chicago.
Badger-Packard Machinery Co., Milwaukee.
Barrett Co., Chicago.
Beaudry & Co., Boston.
Berkshire Mfg. Co., Cleveland.
S. Birkenstein & Sons, Chicago.
G. S. Blodgett Co., Burlington, Vt.
Blystone Mfg. Co., Cambridge Springs, Pa.
Brass World Publishing Co., New York.
Bristol Machine Tool Co., Bristol, Conn.
Brown Specialty Machinery Co., Chicago.
Buckeye Products Co., Cincinnati.
Bullard Machine Tool Co., Bridgeport, Conn.
Carborundum Co., Niagara Falls, N.Y.
Central Electric Co., Chicago.
Champion Foundry & Machine Co., Chicago.
Frank D. Chase, Chicago.
Chard Lathe Co., New Castle, Ind.
Charles J. Clark, Chicago.
Cincinnati Pulley Machinery Co., Cincinnati.
Cleveland Osborn Mfg. Co., Cleveland.
Cleveland Pneumatic Tool Co., Cleveland.
Clipper Belt Lacer Co., Grand Rapids, Mich.
Thomas E. Coale Lumber Co., Philadelphia.
Combined Supply & Equipment Co., Buffalo.
Corn Products Refining Co., Chicago.
"Daily Iron Trade and Metal Market Report," Cleveland.
Dale-Brewster Machinery Co., Chicago.
Davenport Machine & Foundry Co., Davenport, Iowa.
Davis-Bournonville Co., Chicago.
Dayton Moulding Machine Co., Dayton, O.
Deister Concentrator Co., Ft. Wayne, Ind.
Detroit Drill Co., Detroit.
Detroit Steel Products Co., Detroit, Mich.
Dings Magnetic Separator Co., Milwaukee.
Joseph Dixon Crucible Co., Chicago.
R. E. Ellis Engineering Co., Chicago.
Erwin Mfg. Co., Milwaukee.
Federal Foundry Supply Co., Cleveland.

LEIF ERICSON MONUMENT IN JUNEAU PARK, MILWAUKEE. IT IS CLAIMED FOR HIM THAT HE WAS THE FIRST TO DISCOVER AMERICA.

Foreign Crucibles Co., New York.
"The Foundry," Cleveland.
Foundry Appliance Co., Newark, N.J.
Foundry Equipment Co., Cleveland.
Foundrymen's Supply Co., Milwaukee.
Warren F. Fraser Co., Westboro, Mass.
Garden City Sand Co., Chicago.
General Electric Co., Schenectady, N.Y.
General Steel Co., Milwaukee.
Gooley & Edlund, Cortland, N.Y.
Gordon Sand Co., Conneaut, O.
Great Western Mfg. Co., Leavenworth, Kansas.
Norma Co. of America, New York.
Norton Co., Worcester, Mass.
Oakley Machine Tool Co., Cincinnati.
S. Obermeyer Co., Chicago.
Oesterlein Machine Co., Cincinnati.
Ohio Machine Tool Co., Kenton, O.
Oliver Machinery Co., Grand Rapids, Mich.
Oxyweld Acetylene Co., Chicago.
Pangborn Corp., Hagerstown, Md.
Pawling & Harnischfeger Co., Milwaukee.
Peerless Machine Co., Racine, Wis.
Peck Iron & Steel Works, Kalamazoo, Mich.
Sand Mixing Machine Co., New York.
Schroeter Engineering Co., Chicago.
Shepard Electric Crane & Hoist Co., Montour Falls, N.Y.
Simonds Mfg. Co., Fitchburg, Mass.
W. W. Sly Mfg. Co., Cleveland.
R. P. Smith & Sons Co., Chicago.
Werner G. Smith Co., Cleveland.
Southworth Machine Tool Co., Portland, Me.
Standard Optical Co., Geneva, N.Y.
The Standard Sand & Machine Co., Cleveland.
Sterling Wheelbarrow Co., Milwaukee.
Frederic B. Stevens, Detroit.
W. F. Stodder, Syracuse, N.Y.
Strong, Kennard & Nutt Co., Cleveland.
Sullivan Machinery Co., Chicago.
Swan & Finch Co., Chicago.
Thomas Elevator Co., Chicago.
Torchweld Equipment Co., Chicago.
United Compound Co., Buffalo.
United States Graphite Co., Saginaw, Mich.
U.S. Molding Machine Co., Cleveland.
U.S. Smelting Furnace Co., Belleville, Ill.
United States Silica Co., Chicago.
Wadsworth Core Machine & Equipment Co., Akron, O.
J. D. Wallace & Co., Chicago.
Warner & Swasey Co., Cleveland.
Western Electric Co., New York.
F. H. Wheeler Mfg. Co., Chicago.
Whiting Foundry Equipment Co., Harvey, Ill.
E. J. Woodison Co., Detroit.
Young Bros. Co., Detroit.

LAKE PARK.—MILWAUKEE IS FAMOUS FOR ITS WONDERFUL PARK SYSTEM—NO PART OF THE CITY IS MORE THAN WALKING DISTANCE FROM SOME PARK.

SAVE TO WIN

At a time when strong measures are being taken to gather together scrap metal and old rags it occasions no surprise to find a campaign launched for the eliminating of waste in the spending of money. The country needs every dollar that can be saved, and every movement that will promote this end merits encouragement. A great deal is said about the value of the last dollar in this struggle, but the lavishness with which some people spend money would almost incline one to think that the dollar was not of much importance. But it is, and every quarter dollar, too. The larger the number of those who save, the more enduring will be the foundations of our financial and industrial edifice.

Edith M. Thayer, in "Popular Mechanics," says: "Used carbon or transfer paper can be made to last much longer by simply holding it over an open flame such as a lamp, candle, or match, with the carbon side down. The wax substance of the unused parts will melt and run into the thinner sections of the used parts."

Greaves-Klusman Tool Co., Cincinnati.
Grimes Molding Machine Co., Detroit.
Hauck Mfg. Co., Brooklyn, N.Y.
Hausfield Co., Harrison, O.
Hayward Co., New York.
Henry & Wright Mfg. Co., Hartford, Conn.
Herman Pneumatic Machine Co., Pittsburgh.
Hoevel Mfg. Corp., New York.
Holcomb Safety Garment Co., Chicago.
Holland Core Oil Co., Chicago.
Hyatt Roller Bearing Co., New York.

A NOVEL TENSION AND COMPRESSION TESTING INSTRUMENT

By FRANK C. PERKINS

THE accompanying illustrations, Figs. 1, 2, 3 and 4 and drawing Figs. 5 and 6, show a unique form of extension and compression instrument recently described in a paper before the American Society for testing materials and load deformation diagrams and curves of tests made with this instrument. Its applicability to a wide range of specimen sizes, either for tension or compression, was pointed out as well as the ease of use with a satisfactory degree of accuracy and its simple construction and low cost.

It is stated by Prof. S. H. Graf, of the School of Engineering and Mechanic Arts of the Oregon Agricultural College at Corvallis, Oregon, that the device combines in one instrument all the requirements usually met less satisfactorily by several extensometers and compressometers. This universal strainometer is of simple design and consists of two simple adjustable frames, each carrying two screws bearing on the gage marks on the specimen. One of the frames carries an Ames dial and pivots on a rod held rigidly in the other frame, the dial indicating twice the actual deformation.

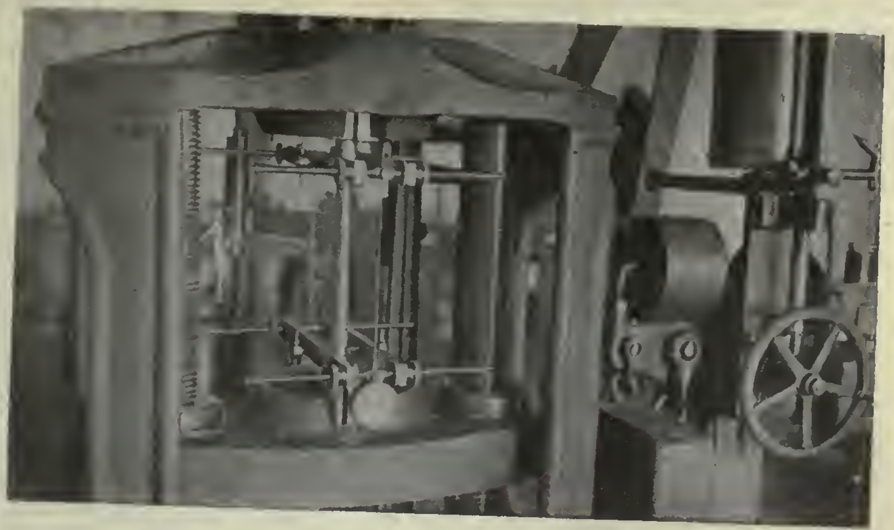

FIG. 2. EXTENSOMETER IN PLACE ON TENSILE TEST PIECE.

FIG. 1.

A toggle clamp prevents the frame from separating from the pivot, and a slender steel rod actuates the staff of the gag head. The error due to tilting of the dial from within the range of any test is of no consequence and within the elastic limit it is not a redable quantity.

The photographs, Figs. 2, 3 and 4, show the instrument applied to various specimens and indicate its range; this range includes specimens either in tension or compression up to 8 in. in diameter or square, and of any gage length from 2 in. up. To adapt the instrument to different gage lengths, for the ordinary lengths of specimens, rods of drill steel, 1-8 and 1-16 in. in diameter, respectively, are suitable, while for special tests where the length may be considerable, light wooden strips with steel inserts in the ends are perhaps most satisfactory.

The accuracy and reliability of the Ames dial when applied to strain measurements has been well established as repeated calibrations of the complete strainometer as just described, both

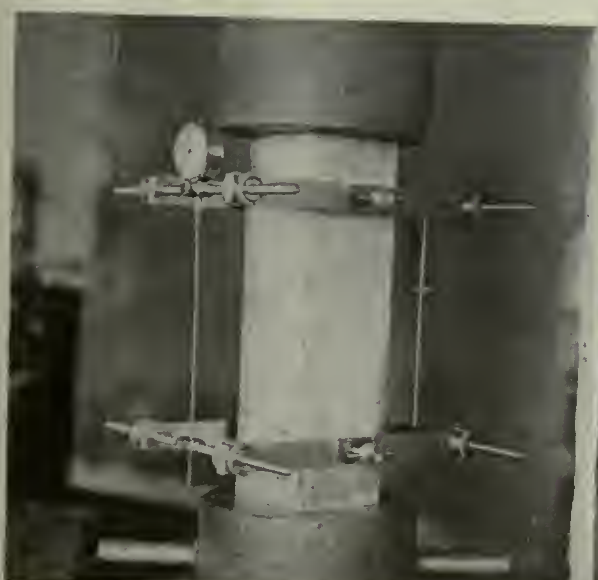

FIG. 4. APPLICATION TO COMPRESSION TEST OF WOOD.

FIG. 3.

against a micrometer and against test bars of known modulus, have shown the instrument to be fully as accurate as others designed to read the 0.0001 in. Some of the extensometers and compressometers on the market, while fundamentally of very precise design, are so complicated and cumbersome as well as slow and difficult to read, that their apparent accuracy as shown by calibration cannot be obtained under operating conditions.

Some objection has been made to instruments having only two instead of three points of attachment, but numerous studies made by means of the Berry strain gage on the distribution of stress in various specimens under test have convinced the author that under proper conditions of gripping tension specimens and of bedding compression specimens, the two point instrument will, with equal care in centering, give the average deformation as faithfully as the other.

If provided with three dials or micrometers the three point instrument is useful in showing roughly the distribution of stress, but this makes the instrument too complicated for all ordinary purposes. Three observers would be required if readings were to be taken on the run, and even when load is applied by increments, it is difficult for a single observer to read three dials or micrometers accurately. It will be seen that this strainometer embodies a combination of principles previously applied in various other instruments and is of great value in experimental work where the extensometer and compressometer have been utilized in the past.

On August 29 the United States government paid out $156,000,000 for ordinary war expenses, making the largest single day's expenditures for these expenses in the nation's history.

TORONTO SECTION HAD GOOD DISCUSSION

American Institute of Electrical Engineers Hear Address By Past President

The Toronto section of the American Institute of Electrical Engineers opened its sixteenth season on Friday, Sept. 20th, at the Engineers' Club, with an address by Mr. Paul M. Lincoln of the Westinghouse Electric Manufacturing Company, East Pittsburg, on the subject of Development of Power Transmission.

Mr. Lincoln reviewed the progress of electric power transmission from its inception, and even presented comparisons with prior developments in power transmission by hydraulic, mechanical and pneumatic methods. The record of early transmissions with alternating current at approximately 1,000 volts was especially interesting in view of their effect on the ultimate standardization of alternating current systems with existing voltages as high as 150,000. Mr. Lincoln discussed the limitations to still higher voltages of transmission, and it is his opinion that, within five years, there will be one or more systems operating at 200,000 volts.

As is common with meetings of the Toronto Section, there was a great deal of very interesting discussion of the paper. Mr. Murphy, of the Department of Railways and Canals, related some interesting experiences in connection with early electrical developments in Ottawa, with particular reference to his experience with one of the first synchroscopes; an early invention of Mr. Lincoln's. The paper was also discussed by Messrs. F. G. Clark, H. C. Don Carlos, D. H. McDougell, P. E. Hart, W. F. Dobson, E. B. Dwight, E. V. Pennell and others.

Mr. Lincoln was tendered a very enthusiastic vote of thanks on behalf of the seventy members present at the meeting.

The next meeting of the local section on Octobr 4th will continue the discussion of Power Transmission to present day problems, as a general discussion is scheduled on the subject of Grounded Neutral versus Isolated Systems of High Tension Transmission and Distribution.

Mr. A. H. Hull, chairman of the Section, announced that in November an official meeting of the Institute would be held in Toronto, at which the president and directors would attend from New York. At this meeting there will be three or more papers presented by Canadian members of the Institute, all dealing with developments of the electrical art in Canada.

NINE MONTHS FOR LETTER FROM RUSSIA

Harmless Epistle Had Quite a Time Getting Through To This Country

There are evidences coming to the surface frequently now of the condition of affairs that existed in Russia during the last few months. There are many Canadian firms who have wondered at times what has become of mail matter that they were expecting from that much worried country.

A letter came to the office of CANADIAN MACHINERY this week from G. Talal, a machinery dealer at Odessa, Russia. Translated it reads:

Gentlemen:—

In reply to your favor of 17th August, 1917, I have the pleasure of informing you that I shall be happy to receive your new "Annual Review Number," which, without doubt, will be very useful to me as I interest myself specially in the industry of your country.

Awaiting the prompt arrival of your publication as well as the pleasure of hearing from you, I present you my compliments,

G. TALAL.

The letter was started on its journey on the 10th of December, 1917, and reached this office on the 13th of September, 1918. It also bears the mark of having been opened by the censor.

British sinkings in eight months of the present year total 1,681,686 tons. Completions total only 1,029,865 tons. Thus the British merchant fleet is steadily shrinking in size, while the Japanese is greatly increasing. At the end of the last great war Britain possessed a larger mercantile marine than at any previous period in her history, and thus it was comparatively easy to make good the ravages of war by drawing upon all the markets of the world. There is no such prospect as things are now tending, yet ships will again be the first requisite when reconstruction begins.

Causes of Failure in Boiler Plates

Effect of Grain Growth—Alteration of Crystalline Structure by Mechanical Deformation—Some Remedies

By WALTER ROSENHAIN and D. HANSEN.

THE occasional cases of failures in boiler plates met with in practice have formed the subject of several papers and discussions before the Iron and Steel Institute in recent years. A number of such cases have been investigated by the authors, and an account of one which offers features of particular importance which do not appear to have been previously noticed was read before the Iron and Steel Institutes in May. These are of special importance because it may be found that they afford a clue to the cause of failure in other cases, particularly in boiler plates of the largest dimensions.

The failure occurred in the last stage of the manufacture of the plate. The size and dimensions of the plate are illustrated in Fig. 1. The plate has a thickness of 1¾ in. and measures 4 ft. 4 in. in width by 11 ft. in length. It was manufactured under a stringent specification, but cracked during the straightening of the edges after the bending operations had been completed. Inquiry showed that the bending operations had been carried out in stages in the cold, the plate being subjected to intermediate annealings between the various stages. The position of the crack which formed in the plate is indicated in the diagram.

The material of the plate was first submitted to chemical analysis, mechanical tests, and general microscopic examination. The results obtained were as follows:

CHEMICAL ANALYSIS

	Per Cent.		Per Cent.
Carbon	0.16	Manganese	0.623
Silicon	0.079	Nickel	0.10
Sulphur	0.030	Chromium	nil
Phosphorous	0.048		

There is nothing abnormal in this composition, which represents a mild steel of high quality.

Tensile tests were taken from the outside and inside of the plate as received, with the results in Table 1, columns 1 and 2:

Here again there is nothing abnormal, except perhaps a slight indication of an unusual condition of the steel in the comparatively large difference between elastic limit and yield stress. It was thought that possibly this peculiarity might arise from the existence of internal stresses in the material, and in order to remove these as far as possible without changing the structural condition of the steel, a portion of the plate was annealed at 550° C. for 30 minutes. The results of tensile tests of a plate in this condition are given in the third column of Table 1. It will be seen that the difference between elastic limit and yield stress is still comparatively large.

In order, further, to test this point, and also to ascertain how far the tensile tests obtained on the material, as received and after annealing at 550° C., correspond to the best properties which the material is capable of attaining, a sample of the plate was normalized by

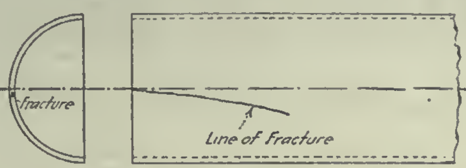

FIG. 1—WHERE THE FRACTURE OCCURRED.

heating to 900° C. followed by cooling in air. The results of tensile tests made on the sample thus treated are given in column 4 of Table 1. Here it will be seen that the elastic limit has come very much closer to the yield stress, while the yield stress itself has been raised. The ultimate stress has only been slightly affected, but, on the other hand the elongation has been markedly improved.

Since the tensile tests showed little or no departure from the normal in the material of this plate it became desirable to apply other tests in order to ascertain whether the properties of the steel were really as satisfactory as the tensile tests would indicate. For this purpose an impact test has been used, for although it is recogized that the conditions under which failure occurs in boiler plate possess no apparent resemblance to those of an impact test, yet experience has repeatedly shown that materials which give a low figure under an impact test are liable to fail under apparently static conditions.

The form of impact test employed is that known as the international notched bar impact test, made with a modification of the Charpy impact testing machine, and on specimens measuring 10 mm. by 10 mm. in section by 53.3 mm. in length, having in the middle a rounded notch with a radius of two-thirds of a millimeter. On the material as received this test gave a mean figure of 0.75 kgm. per sq. cm., the actual values obtained being: 0.84, 0.88, 0.66, 1.08, 0.86, 1.20. These figures are of course very abnormally low, a reasonable value for a boiler plate of this kind being from 8 to 11 kgm. per sq. cm. It was thought that possibly this low value might be

TABLE 1—PHYSICAL TESTS OF THE FAILED PLATE

Particulars.	Plate as Received		Plate Annealed 550° C.	Plate Normalized 900° C.
	Outside 1	Inside 2	Outside 3	Outside 4

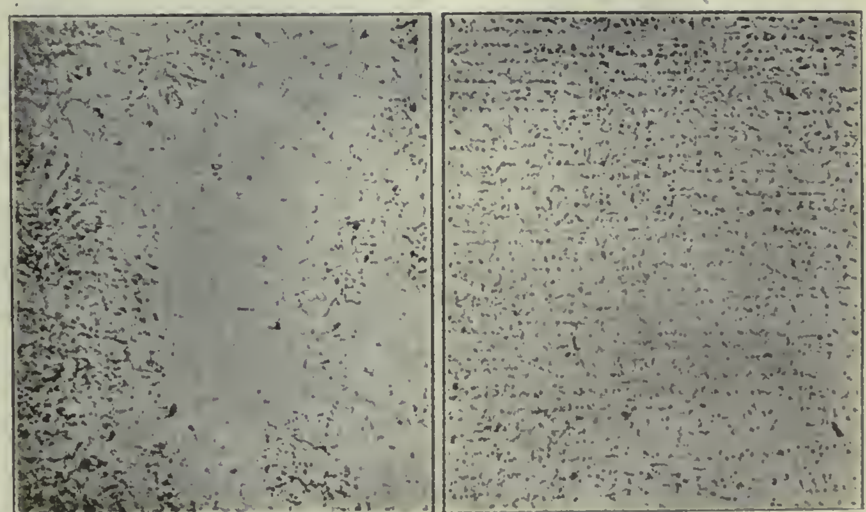
Reduction of area per cent.	59.6	60.7	59.1	62.5

*A gage length of 1.3 in. is chosen to give a ratio of gage length to diameter equal to 3.5.



FIGS. 2 AND 3—STRUCTURE IN TRANSVERSE AND LONGITUDINAL SECTION OF THE ORIGINAL METAL, 50 DIAMETERS. A CONSIDERABLE AMOUNT OF BANDING IS PRESENT.

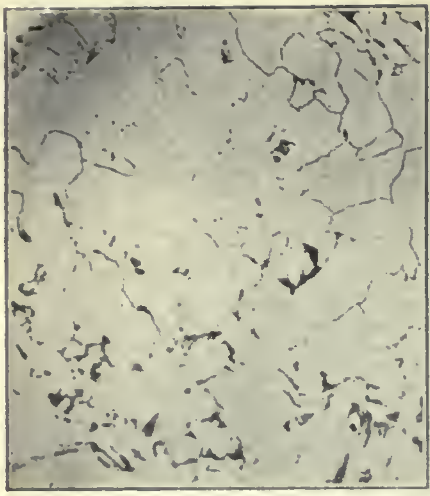


FIG. 4 (LEFT) LARGE FERRITE CRYSTALS IN THE CARBONLESS BENDS OF THE STRUCTURE AFTER FURTHER ETCHING; MAGNIFICATION IS 150 DIAM.

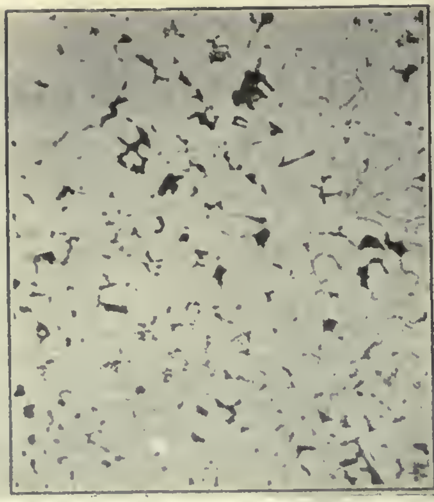

FIG. 5 (CENTRE)—SAME MATERIAL AFTER NORMALIZING; MAG. 150 DIAM.

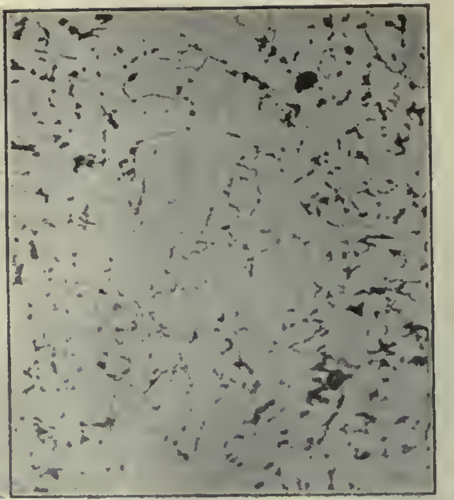

FIG. 6 (RIGHT)—STRUCTURE OF ONE OF CARBONLESS AREAS OF THE SPECIMEN WHICH HAS BEEN HAMMERED IN THE [illegible] AND THEN ANNEALED AT 650° C. MAG. 150.

due to cold work which the plate had received, leaving it in a work-hardened and, possibly, internally strained condition. The impact tests were therefore repeated on specimens of the plate which had been annealed for thirty minutes at 550° C., in the same way as had been done with the tensile test pieces. The mean result of six impact tests made on the steel in this condition gives a value of 2.90 kgm. per sq. cm., the actual figures obtained being as follows: 2.10, 3.86, 2.64, 3.36, 3.52, 1.92.

It will be seen that this very low temperature annealing, by removing cold work and internal stress has improved the impact behaviour of the material quite appreciably, but that, even when thus treated, it is still very far below the normal value for steel of this grade. This is indicated by the impact figures given on samples of the plate after normalizing at 900° C., when values of 10.78 and 11.72—mean, 11.25 kgm. per sq. cm. were obtained.

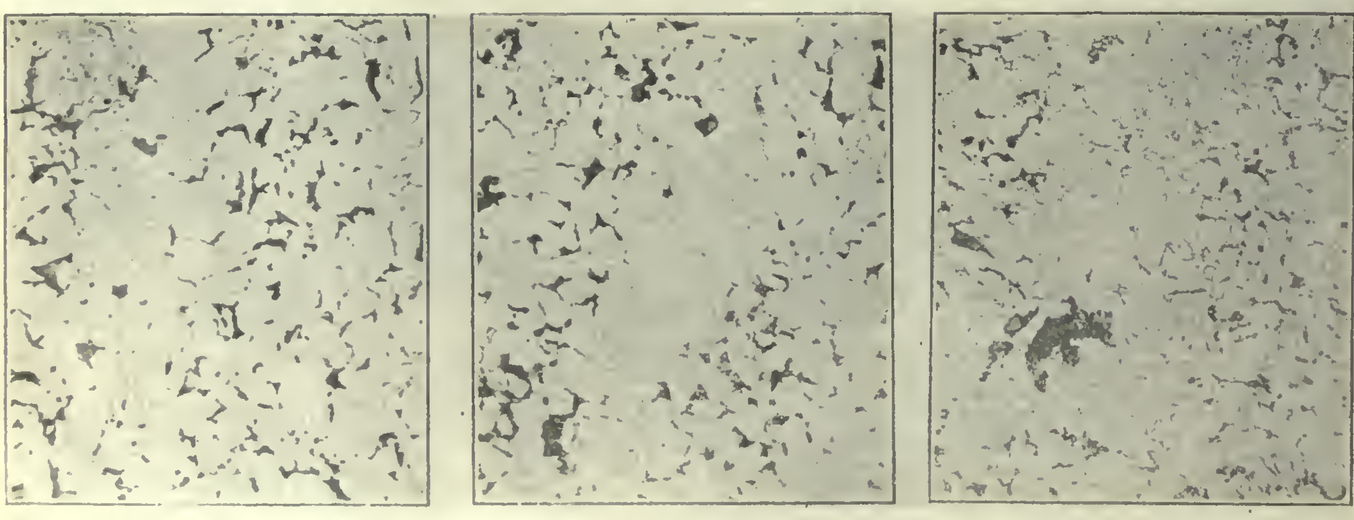
It is evident from these figures that the steel of the fractured plate is in an abnormally bad condition, presumably as the result of some treatment—thermal or mechanical, or both—which it has received during manufacture, and it became necessary to discover, if possible, the cause of this abnormality.

The general microscopic examination of the steel showed at first sight nothing abnormal. The structure in general transverse and longitudinal section is shown under a magnification of 50 diameters in photomicrographs Figs. 2 and 3. It will be seen that the scale of the structure, so far as ferrite-pearlite distribution is concerned, appears to be satisfactory, but there is a considerable amount of banding present, although this amount is not in itself abnormal for a plate of such large size.

More careful examination of the structure, however, particularly after it had been etched in such a way as to develop the ferrite boundaries, revealed a striking pecularity. This takes the form of relatively very large ferrite crystals in the carbonless bands of the structure. These are illustrated, under a magnification of 150 diameters, in Fig. 4. The corresponding grain size of the same material, after normalizing, is shown in Fig. 5 under the same magnification. It should be noted, however, that the normalized structure shown in Fig. 5 has been obtained not by treating a small laboratory sample but from a comparatively large piece of the plate about a foot square which had been subjected to the heat treatment described. The most careful study of the steel in both conditions revealed no other difference between the "as received" and normalized conditions. The inference is thus indicated that the abnormal impact behaviour of the steel as received may be due to the development of coarse crystals in the carbonless bands which occur in this material, and the possibility is suggested that the failure of this plate may be connected with the phenomenon of grain growth which has in recent years been discovered in the case of iron and very low carbon steel.

The subject of grain growth is of fundamental importance in connection with the further investigation of this plate, and it is referred to it in greater detail at this point.

Phenomena which are now recognized as coming under the general title of grain growth were discovered and described by Stead[1] and Charpy[2]. A considerable advance in our knowledge of the subject was, however, made by Sau-



FIGS. 7, 8, 9 MICROSTRUCTURES AT 150 DIAMETERS OF THE STEEL, CORRESPONDING TO THE VARIOUS FORMS OF HEAT TREATMENT OUTLINED IN TABLE 3.

veur[3], who made the well-known experiment of straining by compression a conical piece of nearly pure iron, and subsequently annealing the piece thus treated at a temperature below the lowest critical point. On cutting a section and etching it, a band of very large ferrite crystals was found at one point, and this

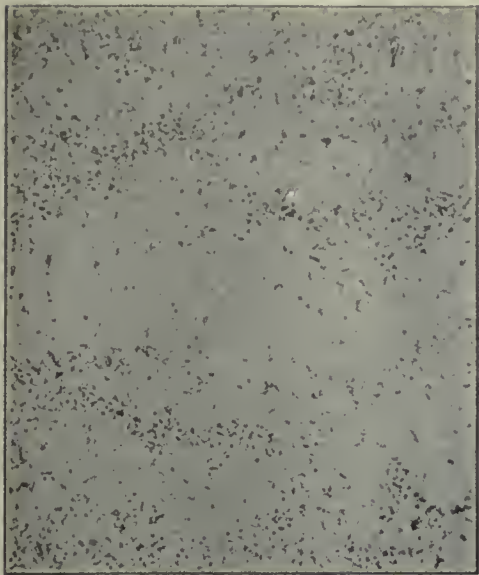


FIG. 10—MICROSTRUCTURE OF PLATE NO. 2 USED EXPERIMENTALLY. VERY LITTLE BANDING PRESENT, THE PLATE BEING ONLY ½-INCH THICK

led to the view that there is a critical amount of plastic deformation which, for a given annealing temperature, below the critical range produces very rapid grain growth.

The subject has been more fully investigated by Chappell,[4] and has also been dealt with in America by Sherry.[5] The latter author has shown that grain growth occurs, not only in comparatively pure iron, but in any region existing in a mass of mild steel from which pearlite is absent or nearly absent—in the carbonless bands such as those met with in boiler plates, provided, of course, that the necessary treatment, consisting of plastic deformation of the right intensity followed by annealing at a correspondingly low temperature, has been applied.

In view of the results obtained by the authors just referred to, the observations made on the boiler plate which forms the subject of this paper at once suggested that the development of coarse ferrite crystals in the carbonless bands of the plate was the result of grain growth following upon deformation in the cold and subsequent low temperature annealing. When it is borne in mind that this plate was bent cold and then annealed several times in succession, it will be seen that the conditions likely to produce grain growth in carbon-free areas had been present.

The authors, however, were not satisfied with a general inference of this kind, but endeavored experimentally to reproduce the conditions under which the steel had developed the coarse and relatively brittle structure which it possessed when received. For this purpose two series of experiments were undertaken. In both series the material was first normalized in order to destroy the previously existing coarse crystals and to bring the material into the condition in which it gives a satisfactorily high impact figure. Deformation was then applied to the material in two ways; in one case, in the cold (by hammering), and in the second case at a temperature between 600° and 700° C., or below the critical range. Specimens treated in both ways were then annealed at 650° C. for 30 min. The microstructure was examined both before and after this last annealing, and impact tests were taken on the material at each stage.

The resulting structure in one of the carbonless areas of the specimen which has been hammered in the cold and subsequently annealed at 650° C. is shown in Fig. 6 under a magnification of 150 diameters. Comparison with Fig. 5 shows at once that considerable grain growth has taken place, although the resulting grains are not quite so large or well developed as those in Fig. 4. The sample which has been hammered between 600° and 700° C. gives a very similar structure, and the impact figure in this case is brought down to 1.56 kgm. per sq. cm.

In order to test the matter further another series of experiments was undertaken in which varying amounts of mechanical deformation were applied in the cold followed by annealing at 650° C. In order, however, to prove that it was not the annealing process alone which resulted in the reduction of the impact figure, the normalized sample was also annealed at 650° C. without previous mechanical deformation. The results obtained by impact tests on specimens thus treated are given in Table 2:

TABLE 2—TESTS ON BOILER PLATE NO. 1

Treatment	Resistance to Impact. Kilogrammeter per Square Centimeter
Normalized at 900 deg. C.	10.46
Normalized at 900 deg. C.	8.92
Normalized; annealed at 650 deg. C....	9.04
Normalized; severely deformed; annealed, 650 deg. C.	11.7
Normalized; reduced 12.4 per cent.; annealed, 650 deg. C.	10.66
Normalized; reduced 7.1 per cent.; annealed, 650 deg. C.	8.44
Normalized; reduced 6.9 per cent.; annealed, 650 deg. C.	10.04
Normalized; reduced 4.9 per cent.; annealed, 650 deg. C.	8.14
Normalized; reduced 3 per cent.; annealed, 650 deg. C.	6.34

In this table the amount of mechanical deformation is measured by percentage reduction of thickness produced by pressing in the cold in a powerful press.

The results given in Table 2 are instructive. It will be seen that large amounts of reduction actually improve the impact strength slightly, but with decreasing amounts of mechanical deformation followed by low temperature annealing the impact strength is very much reduced, although the lowest value obtained in this way, 6.34 kgm. per sq. cm., is still very much better than that

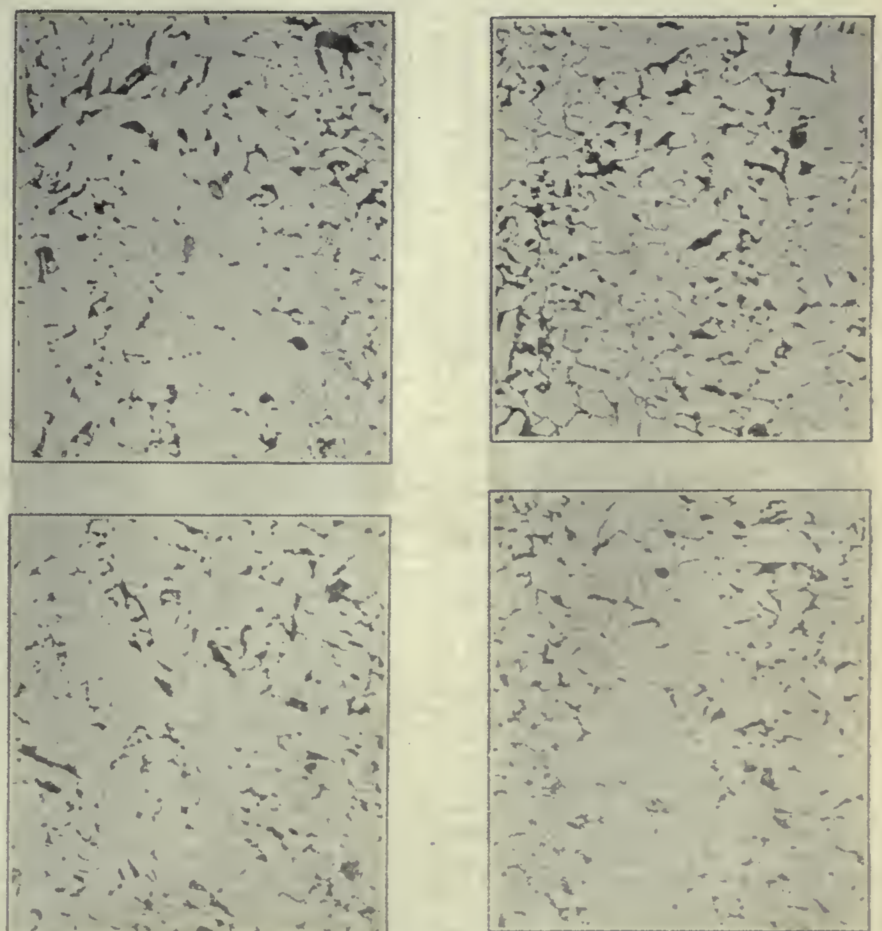

FIG. 11, 12 (UPPER), 13 AND 14 (LOWER). MICROSTRUCTURE OF PLATE NO. 2 AFTER TREATMENT REFERRED TO IN TABLE 2.

found in the plate in its condition as received, or that described in the hammered sample given above. There is nothing to suggest, however, that hammering, as distinct from such deformation as occurs in cold bending, has any specific effect. It should further be borne in mind that when a thick plate is bent in the cold, a considerable range of plastic deformation is produced, ranging from a maximum at the surface of the plate to zero at the neutral axis. Somewhere within this range the critical deformation, corresponding to the annealing temperature employed, is likely to occur.

The microstructure corresponding to the various forms of treatment referred to in Table 2 are illustrated in Figs. 7, 8 and 9, at a magnification of 150 diameters. Fig. 7 refers to the last specimen mentioned in the table having the lowest impact figure and correspondingly showing the largest development of grain growth in the carbonless bands. Fig. 8 refers to the material as normalized and annealed at 650° C. without intermediate deformation. It will be seen that here there is no appreciable difference in grain size between the carbonless band and the adjacent steel. Finally, Fig. 9 refers to the material which has been severely deformed and subsequently annealed at 650° C., giving a high impact figure. Here it will be seen that the grain has been very much refined even in the carbonless areas, and this corresponds in a striking manner with the very high impact figure, 11.7.

When the evidence above described is carefully considered it will be seen to afford a considerable degree of proof of the view that the brittleness, as evidenced by the very low impact figures and actual failure in manufacture which has been found in the plate under discussion, arises from the existence of coarse ferrite crystals due to grain growth in the carbonless bands of the steel, and that this grain-growth is the result of a moderate amount of deformation in the cold, followed by low temperature annealing. It is further evident that normalizing the material, or indeed merely heating it to a temperature above the critical range, is sufficient entirely to obliterate this grain growth and all its evil effects.

It will be seen that this conclusion indicates that the presence of carbonless bands, which is regarded as a normal feature and has not hitherto been considered a serious source of danger or weakness in a boiler plate, may become the cause of failure if associated with a suitable combination of mechanical deformation and low temperature annealing. If carbonless bands are to be regarded as a normal feature in boiler plates—and in existing practice this is probably inevitable—and if deformation in the cold, such as bending, etc., is otherwise a desirable practice, it seems that subsequent normalizing is necessary, or certainly desirable, as a safeguard against dangers of the kind described here.

In order further to test the view which has been advanced above, the authors have endeavored to carry out similar experiments and tests on other samples of boiler plate, but the other samples at their disposal came in every case from plates of much smaller size and thickness, with the result that the banding, where it existed to a marked extent, was on a much smaller scale. Experiments on these plates were, however, made in order that the results might be regarded as a check on the observations already described. In the case of a plate half an inch thick, which may be referred to as No. 2, the chemical analysis was as follows:

	Per Cent.		Per Cent.
Carbon	0.123	Phosphorous	0.057
Silicon	0.014	Manganese	0.49
Sulphur	0.03		

which again indicates a steel of satisfactory composition. The general microstructure of this plate in the condition as received is shown in Fig. 10. A certain amount of banding is present, but not on the scale found in the first plate described. A piece of this plate was

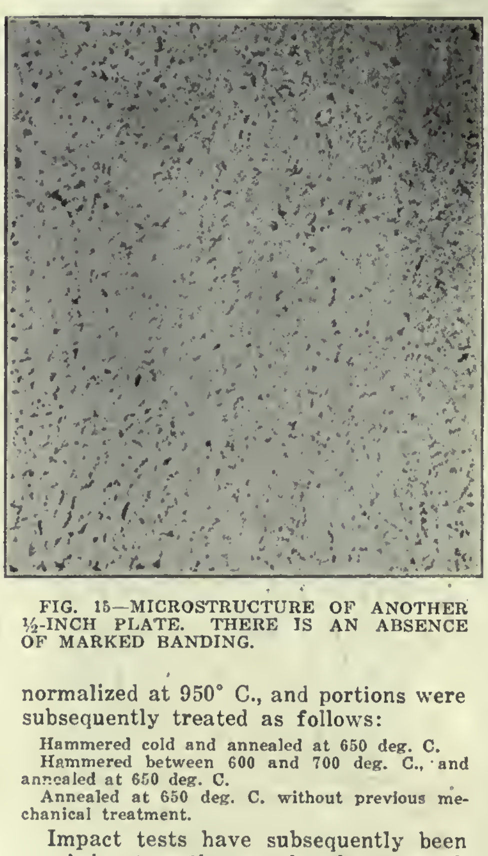

FIG. 15—MICROSTRUCTURE OF ANOTHER ½-INCH PLATE. THERE IS AN ABSENCE OF MARKED BANDING.

normalized at 950° C., and portions were subsequently treated as follows:

Hammered cold and annealed at 650 deg. C.
Hammered between 600 and 700 deg. C., and annealed at 650 deg. C.
Annealed at 650 deg. C. without previous mechanical treatment.

Impact tests have subsequently been carried out on the samples thus treated, with the results given in Table 3:

TABLE 3—TESTS OF BOILER PLATE NO. 2

Treatment	Energy to Fracture. Kilogrammeters
As normalized at 950 deg. C.	11.06
Normalized at 950 deg. C.; hammered cold and annealed at 650 deg. C.	5.52
Normalized, 950 deg. C.; hammered between 600 deg. C. and 700 deg. C., and annealed at 650 deg. C.	7.18
Normalized at 950 deg. C., annealed at 650 deg. C., without mechanical treatment	10.44

It will be seen that the normalized material again gives a high value, and that this value is not appreciably diminished by a further anealing at 650° C. On the other hand, cold hammering followed by annealing at 650° C. lowers the impact figure to one half of the normal value, while hammering between 600 and 700° C. reduces it considerably but to a lesser extent. The corresponding microstructures are illustrated in Figs. 11, 12, 13 and 14. Fig. 11 shows the material as normalized, Fig. 12 shows it after normalizing and reannealed at 650° C. without mechanical treatment, Fig. 13 shows the effects of cold hammering followed by annealing at 650° C., and Fig. 14 shows the effect of hammering between 600° and 700° C., followed by annealing at 650° C.

It will be seen that, in general terms, the results obtained with this material are of the same kind as those found in the first plate but, probably owing to the smaller scale of the banding originally existing in this steel the results are not quite so intense in character. It may be mentioned that this plate also had failed in practice, but not during manufacture, and in a manner which is not necessarily related to the phenomenon of grain growth. The experiments on this plate serve to confirm the observations made with the first example, but they indicate that in plates of a smaller thickness the effects are not likely to be so serious as in the larger plates.

The results obtained with plates Nos. 2 and 3 thus confirm the view that the low impact figures found in the first plate, and to a lesser extent in plate No. 2, are associated with the coarse crystal structure in the carbonless bands, and that these are the result of grain growth produced by slight deformation and subsequent low temperature annealing; also that normalizing in every case completely removes this source of weakness.

New Patents Out.—The following is a list of Canadian patents recently issued through the agency of Messrs. Ridout & Maybee, 59 Yonge street, Toronto, from whom further particulars may be obtained: Samuel R. Kitchen, spring mattresses and the like; Harvey M. Russ, dump wagons; Albert E. Salway, multicylinder internal combustion engine; Joseph H. Price, sights for rifles, pistols and the like; William Wilkie, machines for opening and pressing the seams of wearing apparel in the process of manufacture; John G. Robinson, steam superheater; Robert Blakoe, tires of motor cars and other vehicles; Carl F. Doerschuk, self-locking device; Thomas Mitchell, shim boring and cutting machine; Frank D. Parmenter, attaching means for electric fixtures.

Copper ranks next to steel as the most important war metal. Of a world's production of approximately 3,100,000,000 pounds in 1917, the refineries of the United States produced 2,362,000,000 pounds, or a trifle less than 80 per cent.

THE BASIS OF SCIENTIFIC MANAGEMENT

By M. H. Potter.

IN the course of a short time two establishments in the same industry, in the same locality, built for them in same buildings, equip them with the same machinery and establish for them similar methods of handling equipment and materials—yet, there will be a difference in both the quantity and the quality of their output. This difference in result will be caused by the difference between the two in the quality of their personnel. For this reason alone the question of personnel must ultimately be considered the real problem of management.

If one of the plants mentioned above were headed by a management of the ordinary or traditional type and the other by a management which fully realized the importance of personnel and had developed an active philosophy tending towards the solution of the personnel problem, the difference in practical results would be so great as to be unbelievable by the uninitiated. In fact, this difference alone would often spell failure in the one case and success in the other.

The managers of both plants would see the shortsightedness of letting buildings and other equipment run down for lack of upkeep and repair. Both would see the value of and put into practice means of running the machinery at the most efficient speeds and bringing into use the best tools and the best method of handling material. It would be taken for granted by both that anything that goes to the improvement and upkeep of these things would be a necessary expenditure or a wise investment. The ordinary management, however, would not think of applying the same laws of upkeep and improvement to the personal equipment.

The ordinary or unscientific manager believes that factory management consists of the handling of orders, materials, and machinery, and that the men in the plant are a mere adjunct to these things—a necessary evil. When this type of manager is confronted withe the fact that his organization is less efficient than another he will lay the blame on his employees.

The old type of management would at the least consider expenditures for the development of personnel as an unnecessary outlay forced upon it by unintelligent public opinion, or would consider it a politic expenditure which would bring a certain amount of cheap advertising at the expense of fair wages. The enlightened, or scientific type of management would consider expenditures of this kind not only wise, but also an investment bringing proportionately larger and more permanent returns than all other kinds. Full value of all expenditures or investments for upkeep and improvement of a plant can be realized only when sufficient investment of both time and money has been made for the purpose of improvement and upkeep of the personal side. In fact, the management which has the correct viewpoint will find that the mechanical and material side of the organization will be better developed as a necessary incident to personal development than it would be where this point of view is reversed.

Only actual comparison of the mechanical and other developments in the establishments of up-to-date manufacturing plants would suffice to prove this point. The usual type of management is at the best only beginning to realize the existence of the personal side. As a result, machinery and equipment are almost universally unlimited. In like manner the proper handling of materials and the installation of other methods developed under scientific management have been introduced in the establishments as necessary steps in the development of the highest efficiency of the individual.

Scientific Management

Scientific management aims directly at increasing the quantity and quality of the output of the individual worker. While scientific management in its application must necessarily go deeply into the question of improved machinery and equipment, and while this in itself makes for greater output, nevertheless, a machine is a tool, and, like any other tool, is devised to increase the efficiency of the individual to whose direct and personal control it must always be subject. The question of quality, even in the case where highly developed machinery is used, is almost entirely a question of the personal element. As for the question of quantity, the real measure of accomplishment is not output per machine or per tool, but output per man.

Scientific management will not have completed its mission when it has determined in each industry the best method of handling materials and equipment in relation to workers, but when it has determined also the principles which underly correct methods of handling men. It is the purpose of this article to show what is being done from this point of view and what a little effort in the right direction can accomplish. A further purpose of this article is to bring to the attention of those interested in the future of scientific management the degree to which management is, in the final analysis, the handling of men and to emphasize that scientific management is scientific only in so far as it recognizes the fact.

From the point of view of the writer the responsibility of handling men from the time of their original selection is the most important responsibility of factory management. It is this responsibility which creates the function of employment in its broadest sense. It is only beginning to be recognized, however, that employment is a function of management. Even where considered or essential part of management, the employment function , with few exceptions, consists only of the original selection of applicants.

Scientific employment includes not only the selection of new employees, but also the keeping of every position in the organization permanently filled with the right kind of man or woman. The main part of scientific employment begins after the act of hiring is completed. Considered from this point of view, it is one of the most important functions of management, and one that requires constant scientific analysis and development. While a very small organization may not be able to afford even one person whose sole function is the business of employment, this activity should nevertheless be recognized as a separate and most important function and in such cases administered by the manager or assistant manager himself.

This employment function can under no circumstances be administered preperly by some head or underling of an operating department. Many of the questions with which the employment department has to deal are questions in which an operating head is an interested party; his very position, therefore, disqualifies him from administering this function. The qualifications required of such a person are essentially different from those required of one administering an employment department. Moreover, the qualifications which are generally considered essential to the head of an operating department are special knowledge or mechanical ability and sometimes a certain amount of executive ability. While some executive ability is useful asset in administering the employment function, the chief qualities required are capacity to investigate and judge impartially, tact. a sincere interest in human affairs and a personality that inspires confidence.

Functions of Management

All responsibilities of the management in the direction of personal service, directed toward the welfare and development of the individual, are part of the function of employment.

While as already mentioned, hiring is only a small part of the function of employment, nevertheless, the solution of the problem of selection is of great importance in its bearing on the whole future development of the worker. All applicants are interviewed by one of the heads of the employment department. Certain specific information concerning the applicant is obtained in every case and entered on a blank for the purpose. Information deemed essential consists of

Name and address.
Date of application.
Date and place of birth.
Date of immigration, when naturalized.
Parentage.
Languages spoken.
Education.
Married or single.
Number in family.
Record of previous employment.

The idea should be to keep such records as simple as possible, only the important details being entered.

Information as to past employment is important as a record of experience and earnings. The number of positions held is also an indication as to whether or not the applicant is steady.

Interviewing

The interviewing of applicants is important and requires considerable tact, judgment and experience. Ample space should be left on every application form for making notes as to the individual's special qualifications as well as any other circumstances surrounding the case. As judgment is essential, and as judgment is influenced by immediate impression, no one is employed on the date of application. Postponement of selection tends to bring all applicants in their proper relationship in the mind of one who has the responsibility of their selection. This method moreover, tends to reduce the number of unsteady help who otherwise might get on the payroll.

Application Records, Classification

Application records are classified as to sex, age and apparent suitability. When a position is to be filled one or more applicants are sent for. A definite time is set for their appearance and self-addressed postal cards are enclosed to be mailed in case appointment cannot be kept. At this time selection is made for immediate employment and the fitness of the applicantt is more definitely determined. Since help has become rather difficult to secure in many localities, this rule cannot be carried out successfully, but whenever possible, the results obtained are far more practical.

As a rule in industrial establishments where the question arises at all, only fitness for the work is considered. There are, however, two kinds of fitness to be considered, provided a person is suited for industry at all; one is fitness for the position, the other is fitness for the organization. Of these the latter is by far the more important.

Fitness for the organization is chiefly a question of character. Every organization has a distinct character of its own, which is often recognized as being a tangible business asset. It is essential, therefore, that every member of the organization have a character sufficiently developed or capable of development to be in harmony with the character of the organization. No matter how skilled or fitted one may be to do a given piece of work, or to operate a certain machine, if he is out of harmony with the spirit of character of the organization, he will be an everlasting detriment to himself and all others in the organization who come in contact with him.

The interviewing of the applicant by a trained head of the employment department is the basis of predetermining as far as possible both the fitness for a position and for the organization. In judging fitness for a position, past experience, where there is any, is sometimes a guide. At the best, however, it is a guide of only doubtful value. Personal choice can be taken in some instances also as a guide. This predilection furnishes in itself a valuable incentive. Often, however, it is important to weight carefully all the reasons for the predilection.

The applicant's fitness for the organization, while more important, is more readily predetermined by interview. The interview at the time of employment is very thorough and designed to explain to the prospective employee the character of the organization and its policies, and the responsibilities of the organization to the employee as well as the responsibility of the employee to the organization.

Physical and Mental Fitness

As the aim of the employment department is to keep every position in the organization filled with fit men and women, the question of physical and mental fitness of the individual is of prime importance. The equipment includes a dispensary, separate rest rooms, a waiting room and a consultation room for the factory physician. Through systems of safety devices and instructions, accidents of both major and minor kinds have been reduced to a minimum. Minor accidents when neglected cause a great deal of inconvenience and much loss of time due to infection.

Only one who has gone deeply into the question of health in its relation to efficiency can realize the loss occasioned by lack of knowledge and attention to even the simplest rules of hygiene. A great deal of work is constantly required to educate people to realize the necessity of fresh air, proper diet and regular hours, lack of attention to one or all of which is often the cause of inefficiency. The care of the eyes and teeth is most important and is receiving care and attention from the factory physicians.

Along with the question of physical fitness must be considered the mental fitness of the individual. Not only does his capacity for certain kinds of work, but also his general fitness for the organization and his ability to advance depend to a great extent upon his mental fitness. Education is valuable in industry only so far as it develops the use of intelligence and character. The limitations to the use of such tests must be well borne in mind, and the error of making generalities must be avoided. Tests of this nature can not determine what a person can do, but are valuable only in assisting in determining what he cannot do. Recreation forms a big factor in the follow-up work of the individual. Noonday recreations are beginning to be recognized for their beneficial effect in industrial work. Separate reading rooms and recreation rooms are also maintained.

Library

One of the very useful means toward general education and development of the individual is the library. Good reading is promoted and in many instances special reading courses are provided. Definite information is furnished by the employment department concerning special classes in the public schools and other institutions.

Another feature that has justified its existence is the bank. Interest is paid on all deposits remaining in the bank three months or more. A special department is maintained in the interest of the war savings loans and through canvassing amongst the employees amounts deposited in this direction are increasing regularly.

It is impossible to touch upon all the features of the useful service performed in a practical, daily administration of the employment department. The chief thing is its personal contact and follow-up. Steadiness of employment must be considered not only from the point of view that it is desirable for reasons of profit, but also from the point of view that it is a responsibility of the management to furnish a steady and efficient employee with steady opportunity. From this point of view alone it becomes the duty of the management to standardize the work and working conditions. The standardization of the purchasing and handling of materials to maintain an even flow and an even balance of work is not alone essential, but the balance of employees is also of greatest importance. In most industrial organizations it will be found that there are constantly employed for a given purpose considerably more people than are necessary to turn out the work. In such instances it will also be found that the number of people employed varies to such a degree that there is not only no opportunity given for steady employment, but the distribution of opportunity varies from time to time. Means such as are used under scientific management for determining the standard methods and standard times for performing a task should be used to determine the exact number of people to be maintained in every position.

Sales Policy

In this connection one of the most important things is the sales policy. Many businesses have not a sales policy or sales organization worthy of the name. It is only in exceptional instances that the sales policy and the manufacturing policy are properly co-related. Ordinarily the sales department is administered with entire disregard of its most important function, to market a product that will permanently be of most profit to the entire organization.

Only a thorough realization of all the actual problems and earnest efforts towards their solution will bring results. While the greater part of these results shows in the spirit of the organization and in the spirit of its personal relationships and can only be judged by actual investigation, an important result is a decided steadying of the working force, which can be judged by accurate data.

In regard to "quitters" a little more explanation is necessary. Very few people realize the tremendous cost to industry from this cause. Various estimates of this cost have been made. These estimates vary from fifty to two hundred dollars per person, depending upon the nature of the work and character of employee obtainable and the percentage of old employees who are retired. Taking even the lowest possible estimate, it would seem that any reasonable outlay of both money and effort for the purpose of reducing this industrial waste would be justifiable.

Labor Turnover

For the purpose of compiling comparable data as regards "labor turnover," standard practices should be established. The average standing payroll for any given period should be the basis as this gives the average number of positions to be filled. In case there is a general reduction in the number of positions during the period, the percentage of new employees to the average standing payroll should be taken. In case there is an increase in the organization, the percentage of "quitters" to the average standing payroll should be taken. In the first case that amount by which the number of "quitters" exceeds the number of new employees will account for the reduction. In the second place, the amount by which the new employees exceed the number of "quitters" will account for the increase.

It can easily be seen how intricate are the problems involved in the handling of men. Every step toward the solution of these problems is a step in the direction of democracy. Efficiency as a whole is accomplished by efficiency of the individual and efficiency of the individual is accomplished only by methods involving personal contact.

The open road to talent is an essential to every successful organization. Practically all positions in the organization including semi-executive and executive, should be filled by those who by reason of sheer personal merit have come up from the ranks. One of the most important functions of the employment department is to develop organization spirit and free expression from its source to the ear of the management. In fact, the chief purpose of a scientifically organized department is nothing more than the development of that intimate personal contact so necessary to management.

It is estimated that about one-fifth of the total number of employees may come daily in contact with the employment department. All cases where direct contact with the management would be beneficial should be immediately referred to it. This requires constant daily contact of the management, and brings it into intimate relationship with a great many more cases that would be possible in the average organization of much smaller size. Wherever the management assumes the policy of the closed door, this department may well be shut down.

Results cannot be accomplished in the spirit of charity, but must emanate entirely from a sense of justice. It must be understood that work along the lines described above can never take the place of wages. Such work must have as a reason for its existence not only increased efficiency, but the increased reward to which increased efficiency is entitled. The increase in efficiency in one plant in respect to wages during a period of four years is as follows: Production 45 per cent., average individual hourly wages of 45 per cent., weekly wages 37 per cent., total manufacturing cost of about 10 per cent. During this period the weekly working schedule was reduced from fifty-four to forty-eight hours.

Results such as these are obtainable only when scientific management is scientifically applied. Scientific management will live if for no other reason than that it has faced the problem squarely and recognizes that the science of management is the science of handling men.

AN ELECTRIC CRANE TRACTOR

The accompanying illustration shows an electric crane tractor, having a maximum gross trailing load capacity of 15 tons, with an automatic type coupler for hitching to trailers. It is provided with a removable battery compartment to facilitate interchange of batteries and a balance drive is used.

The crane has a maximum capacity on the hook of 4,000 pounds and it is provided with an electrically operated hoist of the swinging goose-neck type.

As a tractor these electric labor saving devices meet the demand for all short heavy tractor-trailer haulage on ordinary

AN ELECTRIC CRANE TRACTOR

age problems are best solved by these electric tractors hauling trailers, it is pointed out, as they are similar to the payements. They are said to be efficient and economical and have the same advantages as electric trucks. Many haul-Industrial trackless trains, but only on a larger scale, the electric tractor being a full sized and rugged road type vehicle. Such operation is of great value where there is large tonnage to be hauled over short or moderate distances.

While it is possible for the tractor unit, which is the more expensive part of the equipment to be worked intensely, it does not necessarily follow that a tractor trailer equipment costs less than one of motor trucks. A great saving does result, however, from the lessened labor required for drivers and motor truck mechanics. This is a feature needing no emphasis now that a shortage of such labor is an unpleasant reality. This proves to be a fact whether gas or electric types are considered, but is overwhelmingly true where electric tractors are compared to gasoline motor truck equipment.

The electric transportation equipment has a recognized lessened "fire risk" and for that reason electric tractors or trucks are allowed by the underwriters to be operated practically without restriction in and about congested terminals, docks and warehouses, where gasoline equipment is tabooed. It also follows that at least a portion of the haulage problems of all these institutions are being advantageously cared for by the installation of Walker electric tractors.

Its uses as a crane are of the greatest importance as a considerable portion of the freight handled by trailers or other forms of transportation is heavy and unwieldy. Where handled by hand or other slow methods this has always involved a high labor cost. As will be seen this crane tractor is equipped with a swinging electric goose-neck crane on its forward end by which it is possible to expeditiously and economically handle unwieldly and heavy or bulky material. By placing the vehicle in an advantageous position by use of the swinging crane the material is secured, hoisted and transferred to or from trailers, wagons, motor trucks, box cars or convenient piles.

Practically the only limit of rate of working of this novel device is the speed with which the attaching and detaching operations can be carried out. Material in small quantities is sometimes carried on hook with the advantage that the delivery point may be the floor, the top of a pile, or the loading space of a box-car or truck. The article is placed exactly where desired, and for emergency calls the entire operation takes less time than would ordinarily be required loading the article on to a wagon or a truck. The dexterity with which the various operations can be carried out is proving a revelation to the uninitiated, for not only is the time reduced, but the attendant labor necessary is but a fraction of that required by the older methods. This unique equipment is a most effective electrically operated labor saving device and is being extensively introduced into industrial service.

SYNTHETIC RUBBER

A very instructive communication on the difficulties with which Germany has to contend owing to the dearth of the most important raw materials for the war industries was made by Dr. Duisberg, one of the leading chemists of the Elberfeld Farbenfabriken, in the meeting of the Bunsen Gesellschaft, held at Berlin in April last. It will be remembered that in the years 1910 to 1912 Fritz Hoffmann, of that firm, had succeeded in preparing isoprene and dimethylbutadiene, hydrocarbons somewhat resembling benzene, which on long-continued boiling (for weeks or months, it is now admitted) turned into a substance which showed the chemical reactions and some of the properties of caoutchouc. This synthetic product was used as a rubber substitute or as addition to rubber, and the process seemed commercially possible in those days when rubber was in Germany 30 marks per kilogramme. When the price went down to 4 marks, the Leverkusen works of the firm gave the new process up. There was another process, tried and afterwards abandoned, in these works: reduction of acetone by means of aluminum to pinakone, which is closely related to methylbutadiene. The war once more forced attention on these processes. Meanwhile, however, aluminum and acetone had become equally rare and precious. As regards aluminum the manufacture of the metal was taken up in Germany, which has now three works. With respect to acetone, potatoes had been a raw material, but they could not be spared any longer. Bottinger found that with the aid of the bacillus macerans he could make acetone from putrid potatoes, the fermentation yielding a mixture of about two parts of alcohol and one part of acetone; but the bacillus proved very sensitive, and the process was not a success on a large scale. Calcium carbide was then utilised to a larger extent than before the war; it yields, with water, acetylene which in the presence of a contact substance (mercury salts) is converted into acetaldehyde; the aldehyde can be oxidised to acetic acid; blown over another contact substance the acid loses the elements of CO_2, turning into acetone. This process is worked at Leverkusen, at Hochst and at Burghausen on the Alz. The rubber manufacture was then resumed. The rubber industry was not favourably disposed to the new methyl caoutchouc, however, which was not real rubber, absorbed oxygen from the air, and gave trouble in the vulcanisers. This trouble was overcome by the aid of piperidin and other ingredients. The new hard rubber (ebonite) so improved was equal to the old product and dielectrically even stronger; the accumulator boxes of the U-boats are made of this ebonite. The soft rubber, however, was not perfect yet; at ordinary temperature it resembled leather more than rubber, and became elastic only when warm. The addition of dimethylaniline and of toluidine—both valuable products, it need not be pointed out—cured these defects. In the improved condition the rubber is used for making the tyres for heavy motor vehicles and also for artificial teeth. The Leverkusen works can now supply 2,000 tons of rubber per year, which is about one-eighth of the amount of rubber wanted. Meanwhile Merling has prepared isoprene from acetylene and acetone; and that process, though still in the experimental stage, is also regarded as promising. As to the outlook for these synthetic rubbers in normal times Dr. Duisberg was guarded.—"Engineering."

A saving of coal equivalent to 350,000 tons annually already has been effected by the Fuel Administration in its conservation campaign among the steam power plants, it is stated officially. This saving has been effected through the inspection of 300 plants. It is the intention to inspect each of the 250,000 steam plants of the country. The saving is declared to be the result of applying more efficient firing and operating methods. It has been brought about without curtailment of output.

We Want 100 Editors

CANADIAN MACHINERY wants its readers to help edit this paper. There are men in the tool room, in the machine shop, in the pattern room, at the drafting board, in the sales department—all over, in fact, who are good editors. We want them to work for us.

A good editor is a man who can get his ideas over to the other fellow.

CANADIAN MACHINERY wants articles on shop practice, new devices, new ideas. We want stories of how repair jobs have been done, how production has been increased, how you have been helped in your work.

We want anything that has shop atmosphere in it. The man out of the shop cannot be as good an editor for a mechanical paper as the man in the shop. We want an editorial staff that will stretch right across the Dominion.

If you have never written for publication, try it. Your work will be given the fairest treatment here. If you have sketches illustrating your idea, send them along. If they are worked up properly, all right. If they are not, our own draftsmen will attend to this for you.

CANADIAN MACHINERY pays for this work. Some mechanics are making a nice little side line out of this. Besides this, it gives you an added confidence in your work, a new pride in your trade, and it will bring out the ideas of some other fellow who may have worked the same problem in an entirely different way.

In these days of special work on munitions there are numerous ideas that ought to be passed along. Don't take it for granted that all other mechanics have had the same experience as you have passed through. Your ideas may help some person to be a better mechanic.

Address your copy and drawings to Editor, Canadian Machinery, 143 University Avenue, Toronto.

DEVELOPMENTS IN SHOP EQUIPMENT

Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.

STRAIGHT EDGING AND JOINTING MACHINE

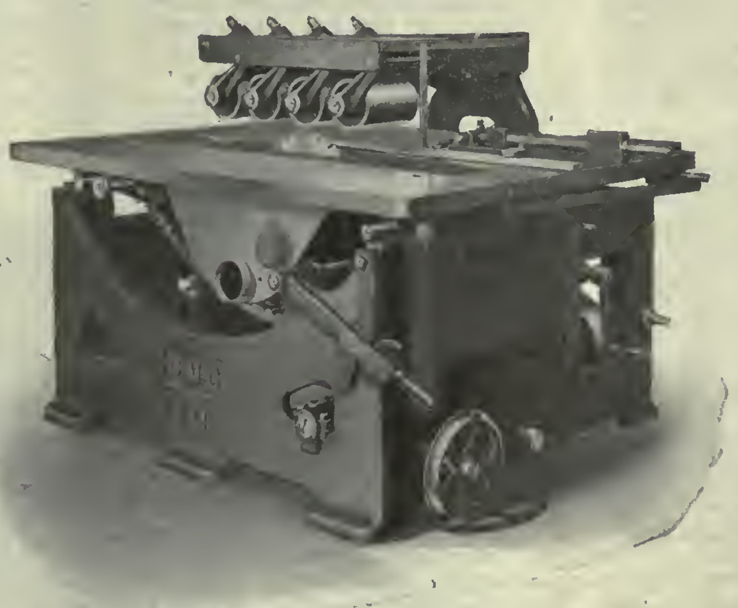
A recently designed wood working tool seen at Toronto Exhibition apart from its mechanical merit deserves attention on account of its strictly Canadian origin and design. In designing the straight edging and jointing machine shown here the Canada Machinery Corporation, Galt, have produced a machine whose excellent mechanical design renders possible accurate and quantity production.

Former machines designed for similar work were made with an overhead movable arm supporting the saw arbor with the feed chains travelling in the saw table and grooved to clear the saw blade. Many disadvantages resulted from the overhead suspension of the saw arbor, cuttings were extremely hard to dispose of properly and short stock was difficult to saw without contrivances apt to get out of order. The placing of the saw arbor below the table and the making of the machine into an under-cutting type at once removes these difficulties and provides a machine which is capable of sawing pieces as short as 7 in. and which permits of the feeding of one piece immediately after another so that the cutting of the saw is continuous.

To saw pieces as short as 7 in. in the older types of machines a smaller blade was necessarily required and, as is well known from experience, a small saw requires a much higher speed and more power to equal the performance of a moderately sized saw and permits of a better cutting angle for the saw teeth.

The drive from the countershaft is extremely powerful, an 8x8 in. pulley being provided for driving the saw mandrel. In consideration of the fact that an adequately supported and well proportioned mandrel is essential to good work the mandrel has been made 1 15-16 in. diameter and is supported in three long 7 in. bearings. An adjustable and thrust is provided for the taking up of end play resulting from wear. The mandrel or saw arbor runs as quietly and as smoothly as a shaper spindle.

In the mounting of the saw blade on the arbor considerable attention has been given to the securing of a strong and rigid connection. 7 in. collars are provided on each side of the blade permitting the use of thin saws and the saving of stock. The saw arbor is carried through these collars and the assembly is securely fastened by a 1 1-8 in. nut on the end. Coned bushings are provided which automatically center the saw in the correct position on the arbor. The provision which has been made for removing saws is an especially commendable feature. Saws can be removed and replaced with the utmost facility, the time taken being no longer than that required to remove blade from an ordinary rip saw. A movable section of the table, on being actuated by a crank, carries with it to one side one of the feed chains and exposes the whole saw mounting to view.



STRAIGHT EDGING AND JOINTING MACHINE.

The feed consists of two travelling chains with serrated surface, one on either side of the saw blade. These chains are supported in long ways provided with adjustment for wear and are cleaned and oiled at each revolution. The truth of cut depends entirely on the travel of the chains whose vertical height is adjustable to suit either rough or smooth lumber.

The stock is held to the feed chains by heavy feed rolls swing suspended and under the action of heavy feed springs. The feed mechanism is driven by a combination of cone pulleys and reduction gears from the saw arbor. Four changes of feed, 50, 75, 115, and 175 ft. per minute, are available through four step cone pulleys actuated by a handwheel. A handle is provided for instantly disengaging the feed.

The production may be estimated from machines in use which are ripping 1 in. kiln dried maple at a rate of 115 ft. per min. and 2 in. similar stock at 75 ft. per min.

The machine when used with a planer tooth saw will take a cut so straight and smooth that the stock can be glued up without further dressing, and one machine can break out as much stock for table tops, dressers, etc., as 4 or 5 hand-feed rip saws. When stock is being edged by hand the operator must keep his blade within the stock, thus wasting lumber, whereas the 6x11 saw will dress along the edge without gouging.

In the design of this machine the operator's safety has been the first consideration and under no circumstance is it possible for the operator's hands to come into proximity to the saw blade, and it is impossible once the stock is engaged in the feed mechanism for it to be thrown back on operator. The efficiency and comfort of the operator is also provided for by the sawdust hood which, on account of the saw being driven from below, carries away all dust and trimmings.

The capacity of the machine is such

that it will take stock 29 in. wide and in thicknesses up to 3 in. with a 14 in. blade.

The table and feed rolls are raised and lowered by sq. thread screws equipped with ball bearings to take end thrust. The fence is instantly adjustable and is of the self-locking type and is provided with a graduated scale on the front bracket.

A workman of average intelligence will in a few days become quite proficient in the operation of this machine.

In one plant two of these saws are in operation On each saw is a boy feeding in stock and a girl taking stock away. This work was formerly done by experienced men, using band rip saws and hand-feed circular saws.

OIL BURNING REFINING FURNACE

A furnace which is adaptable to a wide range of uses in the refining of iron has been developed by Edward H. Schwartz, 436 Marquette Building, Chicago. At the plant of the Garden City Foundry Co., Chicago, the furnace is operated in connection with a cupola and the finished products are refined deoxidized semi-steel, refined deoxidized semi-malleable and gray iron.

In the installation shown the furnace receives iron direct from a 54-inch cupola, the spout from which enters the furnace at one side. Scrap is used almost entirely and often no pig iron is employed in the mixture.

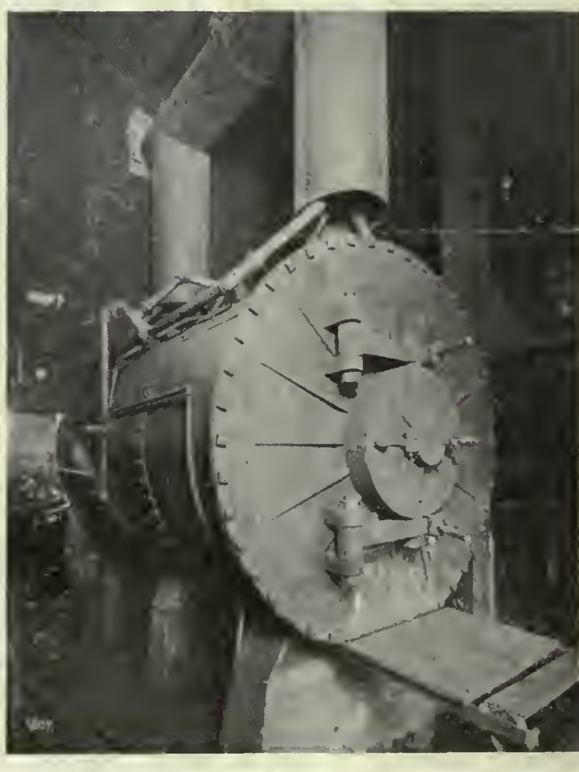
In making the deoxidized semi-steel, steel scrap is charged in the cupola with a small percentage of spiegeleisen to aid in picking up carbon from the coke. This alloy also assists in deoxidizing and supplies manganese in addition to fixing some carbon. In order to supply the proper amount of silicon, ferrosilicon is added after the metal is transferred to the Schwartz furnace. There is a small refining loss of ferrosilicon which is taken into account in proportioning the mixture. Other alloys are added as desired to the charge in the furnace at the beginning of the refining process. An hour of refining is sufficient. A tensile strength of 50,000 pounds per square inch has been obtained in a bar machined from the center of the casting. Steel is produced by charging steel scrap with spiegeleisen in the cupola. Some of the sulphur is removed in the refining furnace by the formation of manganese sulphide. Additions of manganese and silicon are made at the end of the heat. Sulphur and phosphorus also are eliminated in the furnace by the addition of limestone to form a slag. Malleable iron is made by charging steel scrap and spiegel in the cupola with additions of silicon in the refining furnace in the form of ferrosilicon. Deoxidized semi-malleable refined iron is produced by charging malleable scrap and spiegel in the cupola. Silicon and alloys are added in the furnace during the refining process. It is said a tensile strength of 41,000 pounds has been obtained in an un-annealed machined bar. The metal may be hammered like malleable, has bending qualities and takes a high polish.

The refining operation in the furnace is relatively simple. The action of the flame cleanses the metal, removing the free carbon, oxides and occluded gases. The metal is heated until it is still and dead like crucible steel. Slag may be used to remove sulphur and phosphorus if they exist to too high a degree in the scrap.

The furnace is cylindrical with cast steel ends and steel plate walls. It is 6 feet 6 inches in diameter and 10 feet long, and is lined with firebrick to a thickness of 10½ inches. A removable bottom 4½ inches thick extends above the slag line. This bottom consists of chrome, silica or magnesite brick as neutral, acid or basic effects are desired.

The charging door, in the center of one end, is circular. It is mounted on hinged arms and its machined face fits accurately, avoiding the necessity of clay luting. A smaller door in the center of the charging door covers a peep hole through which progress of the refining operation can be readily observed. This arrangement is clearly shown in the accompanying illustration. In the center of the end opposite the charging door an aperture is left for inserting a lighter to ignite the gas at the beginning of the process. This aperture is luted shut after the flame has been started. A testing door and slag hole are fitted on one side. Two vents are placed in the top, one near each end, with a vent hood and short stack. The waste heat from the furnace passing up these stacks preheats air passing down through pipes leading from the outer air to the gas burner. The current of air in these pipes is maintained by the vacuum action of the burner, which has 5 per cent. of compressed air supplied to it. The burners, it is said, are under absolute control by one valve. Three burners are placed in the top of furnace. One, in the apex of the arch, carries only preheated air. The other two are 45 degrees from the apex, in line with the first, and carry mixed gas and air. The currents from the three meet at the center of the furnace. It is claimed that temepratures of 5000 degrees Fahr. have been obtained.

A metal of uniform analysis for the manufacturer of shells is produced as semi-steel, with a tensile strength of 40,000 pounds. The furnace may be operated independently of a cupola, charging the cold scrap direct if desired, but this requires more time for melting and refining. The furnace at the Garden City plant is operated on gas from city mains. It contains about 500 b.t.u. per cubic foot. As stated about 5 per cent. of compressed air is employed, the remaining per cent of air being drawn in by the vacuum thus established. About 10 volumes of air to one of gas are delivered at the burner. Changes in supply of gas and air are controlled by one valve. Gas supply is reduced to obtain higher oxidizing action and the proportion of air is reduced to obtain a reducing effect. During the refining action the flame usually is maintained at the neutral point.



SCHWARTZ STATIONARY REVERBERATORY STEEL MELTING AND REFINING FURNACE

DRAW CRUCIBLE FURNACE

The furnace illustrated herewith has been designed for the consumption of either gas or oil and is adapted to the melting and refining of metals where it is desired to pour the metals out of the same crucible in which they have been melted.

The furnace is cylindrical and is in two parts, the lower part is the combustion chamber and the upper part is the crucible chamber, an airtight seal is formed between the lower edge of the crucible chamber and the combustion chamber, into which the crucible chamber drops when the furnace is closed. Within the walls of both parts is contained a conduit or passage way from the blower to the burner with airtight joints connecting the two units. The combustion and crucible chambers are cylindrical and are lined with a refractory of shapes designed to fill the exact area and to key in place. In the combustion chamber is placed a refractory stool for the crucible and mounted at the rear of the base are columns supporting pulleys and cables which raise and lower the crucible chamber by a pinion, A counterweight being provided to bal-

ance the weight of the crucible chamber. The air in its passage from the blower to the burner is forced through conduit in the walls of the combustion and crucible chambers and reaches a temperature of 450 to 550 degrees and thereby cools the temperature of the walls, giving thorough atomization of the fuel and complete mixture of the fuel and air, which is an essential point in the production of the desired short flame. The flame enters the chamber, tangentially around the stool and crucible completely fills the space around it, and when adjusted properly does not measure in excess of 1½ feet in length. This

furnace is manufactured by the Iler Co., Cleveland, Ohio.

IMPROVED NUT LOCK

The Evertite Nut Corporation, Detroit, Mich., have developed a lock nut possessing valuable features. The action of this nut is simplicity itself. Under forces tending to unscrew the nut a hardened steel ball running between the bolt threads and maintained in immediate contact with them by a spring is forced to wedge in the thread, instantly tightening the nut to absolute immovability. As a result no amount or severity of vibration will ever loosen the nut.

The Stay-lock nut is manufactured from bar screw stock and the special shape given to the nut makes it impossible for anyone to mistake it for an ordinary nut.

The nut is released by inserting a small finishing nail in the key hole and applying a wrench. Should the keyhole become filled with dirt it may readily be cleaned by inserting a pin or small wire.

POTASH IN FURNACE DUST

London.—The Board of Trade Journal publishes a remarkable article on the British supplies of potash, showing the important progress which has been made during the war in the production of potash in Great Britain.

One source of the new supply is from blast-furnace dust, from which potash is obtained by a cheap and simple process, consisting primarily in an addition of a small proportion of common salt to the charge of the furnace, which releases the potash present in the ore and causes it to be volatilized with the emerging gases as potassium chloride.

As the result of experiments on a large scale it was estimated that it would be possible to recover 50,000 tons of potash salts per annum from blast-furnace dust alone—enough practically to meet the needs of the country.

A factory already has been erected at Oldbury, near Birmingham, designed to produce 400 to 500 tons of potassium chloride weekly from blast-furnace dust and a conversion factory is to be added where chloride, not needed for agriculture, may be converted into other refined potash salts. Other factories are in contemplation, and it is expected to obtain especially large quantities of potash from the important Cleveland iron district.

In view of the new importance thus given to blast-furnace dust, dealings in this raw material were placed in August, 1917, under Government control, which is working very smoothly.

Large quantities of potash can similarly be collected from fumes and dust from cement kilns, and potash now is being sold by many cement manufacturers who hitherto had no idea that such valuable material could be so easily collected.

The war has given an impetus to Canadian trade expansion unequalled in our history. In considering the coming of peace the question is put not infrequently to this Department: "What are you doing to prepare for the commercial struggle that will follow the war?" This question and others can be put more appropriately to the business men of Canada: "What are you doing to prepare for the commercial struggle that will follow the war?" "Are you studying the possibilities? Are you studying every phase of the cost of your raw materials, and what effect peace will have on supply, labour, transportation, and market?" The Government has its limitations. It can assist by pointing the way to foreign markets.

J. H. Hall, of the Monometer Mfg. Co., Birmingham, Eng., has invented a machine for recovering tin and solder from old cans and scrap. It consists of an inclined cylinder which rotates within an outer cylinder lined with firebrick. The inner cylinder has at its higher end a feed

Germany Losing Grip on Iron and Steel Sources

RECENT advances in the West Make Her Hold on Great Iron Ore Deposits More Uncertain — Further Advances Will Put Her in a Precarious Position.

GERMANY Has Been Drawing Heavily For Her Supplies on Territory Which She Seized Shortly After the Outbreak of the War — The Steel Trade Watches the Move.

THE steel production of United States and Canada can hardly be increased. In fact it is apparently out of the question for any production figures to be attained that will be sufficiently in excess of what is being shown now to make any appreciable difference. The war needs of the Allies are away beyond the best capacity the steel plants of United States or Canada can hope to reach. At times the trade has been led to believe that it would be possible to have a surplus over war production to be distributed to the commercial trade. And just as often it has been shown that the production of the plants could not take care of the war programme. The commercial users of steel have ceased to look for relief as long as the war lasts.

The Next Best Thing

And so it is that the steel trade on this continent watches with compelling interest the advance of the Allied armies toward those parts of the western front that contain the steel mills and iron ore from which Germany has drawn the great bulk of the material with which to wage the war.

Germany herself is not rich in iron ore, but Germany, with the territory which she seized in 1871 in Lorraine, the land which she overran in 1914, and the domination which she has gained over the steel centres of France and Belgium, has been a greater producer of iron and steel in the war years than ever before. Germany had this well planned, and it has served her purposes to perfection.

Not only has it helped Germany, but it has handicapped France. When France lost the Briey-Longwy fields, she lost from 65 to 70 per cent. of her steel production, 85 per cent. of her iron ore supply, and 55 per cent. of her best mechanics

But In Spite of This—

Mancel Knecht, a member of the French High Commission in United States, and a native of Lorraine, in a recent address dealt most effectively with this very point, stating:

"But in the face of 1,500,000 of her men killed and as many more wounded, and 3,000,000 in occupied territory, she has been able, with the help of British coal and our own steel, to equip by June, 1918, with field guns, 20 divisions of the American army, meanwhile having helped Russia, Serbia, Rumania and other allies not only with prodigious quantities of munitions, but with officers to instruct and train."

The same speaker also gave statistics to show what Germany had gained by securing control of the iron and steel sources on that section of the continent.

In 1913, he said, the annexed part of Lorraine, which was under German domination,, produced 21,000,000 tons of iron ore. And the French part, which had not been taken by Germany in 1871, the part which has been occupied, nearly all of it, since 1914, produced in 1914 19,000,000 tons of iron ore. In the same year, 1913, the whole German territory, excepting the annexed Lorraine part, produced only 7,000,000 tons of iron ore. In the Lorraine district, he continued, we produced in 1914 48,000,000 tons of iron ore, and in your Lake Superior district in the same year there was a production of 52,000,000 tons.

In Lorraine and in Luxemburg there are resources of iron ore, he added, which will exist when there will be no more iron ore left in the Lake Superior district. "We have resources amounting to 5,330,000,000 tons of iron ore in those two little spots on the map of Europe."

He spoke particularly of the ore at Briey, and in spite of the depth of the mines and the necessity of unwatering them, the ore was obtained in 1913 for 4.69 francs or about 90 cents per metric ton. The importance of this deposit he emphasized in explaining that its output amounts to 76 per cent. of that of the Longwy-Briey-Nancy district.

Meanwhile France has been developing a rich iron ore in Normandy, and Mr. Knecht expressed a lively conviction that before long the much-talked-of tunnel under the English Channel will be a fact and French iron will go into England and France will be getting in return the coal she needs from England and Scotland.

Menaces Germany's Control

And so it is that the recent advances that push the danger zone nearer to Germany's control of the iron and steel sources are of unusual interest to this country. Robbing Germany of iron and steel is one grand master stroke. It means lessening Germany's supply of steels, of munitions, of guns—it means that where she fired two shells she may find it hard to find one. It means, in short, that Germany's power will be weakened. There is nothing surer than that.

The steel plants in Eastern France are mostly at Longwy, Briey and Nancy; in Belgium they are for the greater part near Charleroi and Liege. In German Lorraine, Thionville can be said to be the centre of the industry. The iron ore fields are fairly well distributed. In the north the ore is at Longwy for the most part, Briey in the more central territory, while to the south Nancy is the centre. About one-half the pig iron of Europe is made from these deposits, now almost entirely controlled by and operated for the benefit of the German war machine.

Germans Have It In Figures

Germany is well aware of the immense advantage that her early war operations have been to her. The Hun war machine has it all reckoned in stacks blown and tons produced. Before the Association of German Ironmasters in Dusseldorf, on January 30, 1915, Dr. Emil Schrodter, in an address, said:

"In France, Germany now holds parts of 10 departments, covering an area of about 5,250,000 acres with a population of 3,255,000. This means a German control of 68.8 per cent. of the coal output of France; 78.3 per cent. of the coke output; 90 per cent. of the iron ore; 85.7 per cent. of the pig iron output; 76 per cent. of the raw materials, including 95.3 per cent. of the basic Bessemer steel and 76.9 per cent. of steel castings, and the entire output of tubes. All but one of the French locomotive and railroad car plants are in German hands. For wrought tubes the French will have to rely on British and American supplies. Practically all of the French iron-ore mines are in territory occupied by Germany.

"Out of 170 French blast furnaces, 95 of the 127 in blast when the war broke out are in the war zone. Because of ore scarcity only 30 of those still in French hands are able to run, and many of these are small. Hence 80 per cent. of the total French blast-furnace capacity is out of commission. Of the French steel plants 70 per cent. are in German hands. Steel plants uninjured are largely idle. At the horse-shoe works at Valenciennes enormous stocks were found and appropriated by the Germans."

Summing up as to France, Dr. Schrodter said: "While we on the German side are able to draw upon enemy stocks, the French army is deprived of the greatest part of its manufacturing resources and has to get its material from foreign countries. Hence France has already been so severely hit as to cripple and partly destroy her economic power."

Germany Fears It, Too

And so it is that Germany seeks to secure iron ore from Sweden. Sweden has the ore, and it's good ore, too, but Sweden depends on the Allies for a good many supplies. So if Sweden choses to sell iron ore to the Hun the Allies may be inclined to cut off certain supplies without which Sweden would be in a sorry way. And so Sweden may hesitate, and the chances are that she will.

The American advance that wiped away the salient at St. Mihiel means much. Germany knows what it means, and the steel trade knows what it means. And every move that brings the Allied forces closer to Briey means that Germany is going to lose the power that she has gained from stolen iron. The progress of the battle is interesting. There's more in the outcome than a few miles of territory. Without iron and steel Germany or any other warring nation is beaten hands down, and the day when Germany is going to lose her grip on the iron ore deposits and the blast furnaces of France is coming very close. Watch it.

TORONTO MAN BELIEVES HE HAS NOW SOLVED THE MAKING OF THE CAST SHELL

A SHELL that would require no machining of any kind, but would come from the mould practically ready for filling, would reduce the cost, and increase the output of shells enormously. If this shell should be cast from a mixture of semi-steel that made a metal of perfectly homogeneous structure, with an even distribution of its component parts, and giving high tensile strength, a revolution in shell making might be anticipated.

Such were the thoughts animating J. C. McLachlan, of Toronto, when the shell industry was getting well under way in the first year of the war. He began to work on the idea about three years ago, and first experimented in moulding, to overcome the difficulty of keeping the core perfectly central in the mould, to ensure the walls being of even thickness. This was not achieved without a long course of experimenting, but finally he succeeded in turning out a perfect shell. Then began the usual vicissitudes of the inventor, the British Government were approached first of all, through their Canadian agents, but they promptly turned their eyes against it, as they would not consider any shell made from cast metal, their objection being that a casting would not stand the shock of the firing charge, resulting in the shell bursting as it left the gun.

Given A Test

Mr. McLachlan succeeded in getting the ordnance department in Quebec to make a practical test, by firing some of the shells, the test demonstrating that the shells could be fired without any danger of fracturing. Nine shells in all were fired, and afterwards recovered, none the worse for their trip. About this time the inventor was getting in touch with the U. S. Government, and incidentally, got in touch with the German spy system.

How Germans Worked

The U. S. had not yet got into the war, but Mr. McLachlan received a message from a man in New York, offering him all his expenses to go down there and demonstrate the making of an 11-inch shell. As he did not wish to go to the States at the time, he suggested his correspondent should come to Canada. This met with refusal at once, and offers of still more liberal treatment. Finally he decided to go and see what was doing. He met his client, who called himself Grey, and was dressed in the height of fashion, and carried as much ready money as the Bank of Montreal. Mr. McLachlan was entertained royally, and it was arranged he should get the use of a small foundry cupola, and make an actual shell. While arranging for this, the U. S. declared war, and Mr. Grey vanished. It was then that Mr. McLachlan found that the Allies did not use 11-inch guns, but the Germans did.

French Government Using Shells

Mr. McLachlan submitted his shell to the French Government, and they tried it out successfully, and have been using it in considerable quantities for some time. Mr. McLachlan has not as yet made anything financially from his invention, but he is not worrying over that. The U. S. Government have now taken up the shell, and have drawn up specifications and sent them out broadcast to Canadian as well as U. S. foundries. It is therefore quite likely that in the near future the manufacture of these shells in Canada will be an accomplished fact. Probably the British Government may then look further into the matter.

N. A. S. E. Outing.—As usual the Lunkenheimer Company of Cincinnati, royally entertained the delegates and visitors of the N. A. S. E. national convention held in Cincinnati during the week of September 9. The company obtained permission to use Cincinnati's wonderful Zoological Gardens on Wednesday afternoon and evening for their outing, and, judging from the large attendance every one visiting the convention was present. Amusements of all kinds were arranged for by Lukenheimer representatives. The vaudeville was particularly enjoyed, especially the ice skating upon the only outdoor artificial ice skating rink in the United States, the performers being the very best that the profession afforded and were brought from Chicago solely for this affair. Amusements, cigars, drinks and an excellent dinner were all furnished gratis to the delegates and their friends by the Lukenheimer Company. Over fifteen hundred people were dined and all were greatly surprised at the order and despatch with which the meal was served. It was the consensus of opinion of the delegates and their friends that the Lukenheimer outing made the 1918 convention one of the most enjoyable and interesting ever given, and one long to be remembered.

Quebec.—It is stated that a company in Quebec is considering the building of thirty wooden vessels, of five thousand tons each.

Vol. XX. OCTOBER 3. No. 14

British Labor Favors Tariff Reform.

JOHN HODGE, British Labor M. P., and Minister of Pensions, told the Iron and Steel Trades Confederation that if the Labor party were pursuing the policy of Free Trade as it had existed prior to the war, his connection with the party must cease. To him the war had demonstrated very clearly the need for an economic change. Speaking from an intimate knowledge of the steel and iron situation, he expressed the opinion that he was not inclined to let any steel into Britain as long as there was an idle furnace. He was also out of touch and sympathy for that section of the Labor party which declared for no annexations and no indemnities.

John Hodge was not a tariff man before the war. To him the policy of free trade was correct and sufficient. But he is able to see and recognize changed conditions. He does not hold to a theory in preference to recognizing a fact.

John Hodge may have a lone furrow to plow for a few turns, but the same serious circumstances that pointed out the need of a changed policy to him will point the need to others. Making Britain the dumping ground for the over-production of all the world is poor stuff for an after-war policy.

Coal Situation East and West

THE miners in Pictou county, N.S., are out on strike, and have been since early in September. In district 18 of the U.M.W. of A., which takes in Alberta and British Columbia, a strike is likely in a large section of that country, as there is a dispute which has not been settled between the miners and operators.

This, with winter only a few weeks away, and with tremendous demands being made for coal for war industries and other purposes, presents a mighty poor lookout.

The mining of coal in Canada is a poor index of the coal that could be mined in Canada.

Western Canada has a coal wealth that should make her prosperous the year around. The southern part of British Columbia should be busy and developing all the time. It is not. About half the time it is tied up with strikes. On operation and tie-up it looks like a fifty-fifty proposition.

There is a foreign element in Western Canada that is making trouble. That element is feeling its power to-day as it has never had a chance to do before. It is bluffing the whole Dominion, and especially the West. It is playing fast and loose with the big question of supplying Western Canada with coal this year.

In the East the situation is hard to understand. That district has not had to deal with the foreign element to the same extent as the West, and yet, with industries there calling for coal for war work, and with a known shortage facing the whole district, the miners ignore their contracts and refuse to work.

The Department of Labor has not shown itself big enough to deal with these matters. It approaches them with a timidity that is humiliating and dabbles with matters with a ten-foot pole that should be taken up with the bare hands of determination.

A Bit of a Sermon

SOME folks is makin' money now they never dreamed before, and where they used to earn one bone, by heck, they're gettin' four.

Some chaps I knew not long ago could hardly chase around, to raise the coin 'bout twice a day when eatin' whistles sound—they lived close down unto the ground, they were all in by noon, because at fodder time they had a shoe string and a prune.

They only had one suit of clothes to spread upon their skin, and that there suit was worn, it was, until 'twas mighty thin.

They had some patches on the coat, some pieces in the vest, it was a shame, by jing, it was, to call it Sunday best—and there were hunks of cloth nailed on of many hues and slants, to decorate the garments that bore the name of pants.

But all them things is changed, they is, there's money now to spend, and they're clothed in rags what's mighty fine from front unto the end.

They used to smoke a bum cigar that smoked just like a stump, and labelled him what puffed it a lobster and a chump—but nowadays they use the stuff that's wrapt in silver foil, you'd never think they used to be a lowly son of toil.

But when these times is on, me boy, just think about the change, just sit some night and put your feet upon the kitchen range, and see if you ain't goin' dead wrong to spill your wad like that—you'd better give your brains a chance what camp beneath your hat.

So when the cash is comin' thick, when pay day's growin' fat, look past the end of your old snout to days what may be flat; just take a ten spot now and then and put it down to soak, against the day when your good thing may be all warped and broke.—ARK.

A man may not have much of a tooth in his jaw for oleomargarine, but when butter's touching the 60 per mark and oleo hangs around the 35 shot, the chances are that said oleo will be given a box seat at the kitchen table performance.

* * *

Toronto school board finds that it can't enforce the regulation for children to salute returned soldiers. The chances are that a square deal from all concerned would be much preferred by the soldiers to all the manoeuvres that the youngsters could shake out of their carcasses.

* * *

The Kaiser started the war with six sons, and the family roll call shows them all above the daisies yet. It's a caution how this half-dozen war scarred veterans dodge bullets. The next big job for the Kaiser will be to save enough out of the wreck to provide for his sons. Guns aren't shootin' far enough to hit 'em.

* * *

The government paper investigation is calling Canadian publishers to meet at Ottawa on October 16, to consider how the use of newsprint can be curtailed. The suggestion is made that comic supplements should be cut out. That's all right, but if that's done some of them wouldn't be worth buying. The juvenile circulation would shrink to nothing at all.

YES, THERE'S ALWAYS ROOM AROUND THE TOP

Interesting Experience of Man Who Secured His Education After He Left the School House

By H.A.T.

SATURDAY evening of last week I had a talk with Fred J. Milne, mechanical superintendent of the Pure Gold Manufacturing Company. In relating his experiences he impressed upon my mind certain pictures, and I cannot do better than let his words reveal these to you, after I have disposed of a few attendant particulars.

FRED J. MILNE

Fred. Milne was born in the city of Toronto on the 28th day of July, 1881. His parents moved to the United States while he was still a very little boy. All the school-given education he received was that imparted by a public school in Buffalo, N.Y., and another in Dayton, Ohio. Add that he earned as he learned; that he was, in fact, the first boy in the messenger service of the Western Union to own a bicycle—a bicycle that he himself built by giving a semblance of the vertical to the outward-spread rear forks of a tricycle, shortening the rear axle and discarding the surperfluous wheel; add, also, that at the age of twelve he was an apprentice in the Dayton Computing Scale Company's plant, and you have a fair idea of the educational equipment with which he set out to best the mechanical world.

At this time, as chief engineer in the plant of the Dayton Artificial Ice Company, the lad's father was making 321 tons of ice every 24 hours—something to talk about years after 1893. So possibly this proud, but cold, record, and the ice plant's battery of 12 boilers and a pay envelope by a few bits of silver fatter than $1.50 a week may have jointly conspired to attract the boy; or possibly, remembering the lad's age, to "work with dad" was inducement enough. Certain it is that young Milne moved from the scale plant to the ice plant before his full time as an apprentice in the former had been served. And for two years following, in the ice plant and in the Lockland Woollen Mills, he worked to good advantage under his father.

"I was turning 13 when I went back to Buffalo and apprenticed myself to the Rogers Company. Their shop made circular saw sharpening machines. The foreman was a big German.

"In that shop we had to forge and draw all our own tools.

Where He Met the Hun

"Even our flat drills we had to make from diamond steel. Many a day I shaped a tool on the anvil, under a hammer that was a sledge to my strength. And that big GerHun stiff stood near and timed me. And more often than I like to recall he towered over me and my lathe.

"'You'll do it right, damn you!' he'd say. And then he'd stand and curse for half an hour at a stretch, while tears rolled down my cheeks and fell as coolant on the casting in my lathe. Only they were hot tears.

"But I stayed with it—and him—until I had served my full time as an apprentice—sixteen months in that shop.

"The day after my time was up I was working for the West Tool Machine Company, of Buffalo. In this shop we made tinners' machinery; that is, machines for cutting tin, crinkling galvanized sheet metal, etc. I wasn't a great while in this shop nor in the next. For the old folks were returning to Canada, and I wanted to go along.

"I did—as far as Hamilton. Here I took the first job that offered—making catsup and boiling strawberries for the Simcoe Canning Company.

"Not on a bet, to this day, will I eat a preserved strawberry. And in spite of the fact that I burned up a whole kettleful of them, after almost 72 hours on the job without sleep, I was the last one paid off at the season's close.

"I'll not forget that winter. It was hard and times were bad. I wasn't more than 15, and out of a job. As weeks passed, and no work could be found, things became desperate for me. I decided to make work—and money.

"I built a hand sleigh and on top of it rigged up a stove out of a link of old stove-pipe. Then I spent one dime for a bag of charcoal and another—the last I had—for acid. I had a soldering iron and a bit of solder. So I built a fire in the stove and started out as a tinker, prepared to mend old pans and kettles.

From house to house I went in the outskirts of Hamilton—in the outskirts because I had neither a license nor the price of one.

The Going Was Hard

"But holey pans were scarce that day. The only thing that wasn't scarce was trouble. My sleigh overturned and caught fire. I put the fire out with snow, gathered up the spill and trudged on to the next house. There I got my first job—a leaky sauce pan and a boiler.

"I rebuilt the fire, heated the soldering iron, got the acid handy, and set to work. But I couldn't make the solder stick. I worked for a long time. It wouldn't stick. And there was a good reason for that, as I finally discovered.

"The acid must have poured out at the time of the spill, for the liquid left in the bottle, only a few drops, was snow water.

"After that venture I got to Toronto—some way. For a time I was cash boy in the window shade department of Eaton's. Paid $2.50 a week. Later I worked in several plants here, both before and after I went to 'the woods.'

And in one of these particularly—the power plant in connection with the W. A. Murray store—I got useful electrical experience."

Mr. Milne explained that by "the woods" he meant the village of Wilberforce, at that time named Pusey. Here he joined his prospective father-in-law in a wood-cutting industry that did not prove so successful as it might to-day. And here, too, he was engineer in the Thomas Beck saw mills.

Eleven Years Ago

"It is now 11 years since I started in the Pure Gold plant as engineer," he continued. "I've seen it grow to its present size, and I've installed all the mixers, those great hydraulic presses, all the electrical power equipment—practically every machine operating in it to-day.

"I was promoted to mechanical superintendent a little over one year ago.

But his story would not all be told if I stopped without mentioning that his salary would make many a petty executive envious, any more than it would all he told if I failed to say that his son is a clever apprentice in the plant of the Consolidated Optical Company, or that his little girl, musically gifted, is being trained by the Toronto Conservatory of Music, or that the good mother looks as young as her children.

And still another thing I noticed—a library of 15 to 20 mechanical and electrical engineering textbooks. These books Mr. Milne has had for about 11 years. That fact, considered with all that precedes, seems to CANADIAN MACHINERY to be very significant.

MARKET DEVELOPMENTS

Cutting of Non-Essentials Improves Situation

Phonographs and Passenger Autos Will Not be Made in United States After First of the Year—Government Places Very Large Order—Equipping the Canadian Expedition That Leaves Soon For Siberia

CANADIAN dealers who have been in the United States market looking for machine tools report that the biggest concerns there are not looking for business. As a matter of real fact selling has ceased to be part of their business. It is now simply a matter of production and leaving the disposal of the material to the government. Some idea of the volume of business moving can be gathered from the following. The manager of a large Canadian firm was in Cincinnati where he wanted to order a dozen electric drills. At the same time he was in the offices of the company there came an order from Washington calling for delivery on an A-1 rating of 600 of these same tools. The government controls the situation absolutely.

There are still delays in the equipping of Canadian plants that are preparing to take on American war orders. In a couple of cases there is not a little embarrassment following the delays. A large amount of the capital has been put into plant, and the government allowance in the way of advances has been used, while a large overhead remains to accumulate against the day when there shall be deliveries to balance the account. Every effort is being made to relieve the situation, but it is quite a distance from being satisfactory yet.

The war continues to make all sorts of new calls on the machine tool equipment of the country. This week agents are busy gathering up a list of machine tools for the equipping of the Canadian force that is going to Siberia. This force will run into facilities for repair and upkeep work that will be poor or of a zero quality, and for this reason the necessary equipment for shop work is being sent along with them.

Canadian trade is looking for something better in the supply of plates than has been coming to this country for some time. The United States has been cutting off so many of the non-essential users that there is bound sooner or later to be an improvement in the situation. Every week sees a cut made in the list. This week it is announced that the U.S. War Industries Board requests the manufacture of passenger automobiles and phonographs to stop by the first of the year. In the latter case it is not the amount of steel that is thought of, but the inroads that the business makes on the labor market.

SHIPBUILDING BECOMING THE CHIEF INDUSTRY AT MONTREAL

Special to CANADIAN MACHINERY

MONTREAL, Oct. 3.—The volume of business that is being carried on throughout the industrial field to-day is confined to the amount of material that can be delivered to carry on this business. As a matter of fact it is this feature that virtually controls the general situation. Regarding machine tools the time of delivery is the factor that determines the price, as the latter is based on the market at the time of shipment rather than a fixed price at the date of the placement of the order. The demand for tools of a general description has been additionally heavy of late and dealers are unable to satisfy the requests of the manufacturers, as the builders are unable to construct the necessary equipment in the time specified, and unstated delivery must necessarily be a feature of an accepted order.

It is understood that a quantity of the 12 inch shell is included in the recent large contract received by the Canada Cement Company, and a factory for the production of these shells is now under construction at Rockfield, P.Q. A report, which has virtually been confirmed, is to the effect that the manufacture of a cast iron shell for the U. S. government will soon be taken up by the munition makers here in Canada, and it has been intimated that negotiations to this end have been under way for some time. Shipbuilding has been making good progress here and plates for steel vessels are coming along regularly with the yards amply supplied for maximum operations. Yards working on wooden boats have experienced a little delay in obtaining lumber for the superstructures. This situation, however, is less acute at present as shipments are much better.

Steel To-day Means Shipbuilding

When summing up the activity in steel at the present time the situation could be explained in the one word—shipbuilding. The importance of this industry has overshadowed every other enterprise and the requirements for ship plates must receive precedence over every other demand. One local dealer traveled to Ottawa to see what could be done regarding some steel plate for general industrial requirements, as many local concerns were urgently in need of material for plant repairs, but little success resulted from his efforts as he was told that unless the plates were required for steel ship work, his request would receive little attention from the War Trade Board. This feature of the existing situation was additionally emphasized by another steel producer here when he intimated that it was very difficult to obtain the necessary material for the making of wrought iron pipe. In explanation of this the manufacturer stated that the same mills that could produce the blanks for the large size pipe could be utilized for the production of ship plates, and the heavy requirements for this material allowed little tonnage to be produced for pipe purposes. The volume of output devoted to the making of pipe was therefore confined to the short periods between the ship plate rolling process. It will be noted that the latest price list (37) on wrough iron pipe incorporates a slight change in the method of quoting prices. In previous lists the quotations for standard lap-welded pipe have been based on a price of so much per hundred feet. The changes going into effect with the latest list are on the old basis for pipe up to and including 4 inches diameter, larger than this, or up to 10 inches, the quotations are made at so much per foot. The prices of lapwelded pipe have advanced in the recent list and these changes will be seen in the selected market quotations. In nearly every direction the steel situation is feeling the pinch of ship-building and shell requirements, and little material is available for other purposes unless it can be clearly shown that such needs are in keeping with the essential regulations of the War Trade Boards. The co-operation of the two governments in this respect is so close that nothing can be obtained without the sanction of one or both bodies.

Market Being Eliminated

The general market is being more or less influenced by the price fixing that has featured the American situation during the past summer, and this has been a factor in establishing the prices that are now effective in this market if it can be said that a market really exists. Regulations under which all transactions are carried on has virtually eliminated the old time market, when price fluctuations were largely a factor of current developments. With the actual supply being devoted almost exclusively to war requirements and these requirements allotted by the War Trade Boards of the two countries, the changes of quotations are invariably set at certain periods and any changes are determined by the conditions existing at that particular time. To obtain material at the present time it must be shown that the purchaser is operating on essential war work or that directly associated with it. Unless this is so it is next to impossible to secure material. The copper situation is unchanged and prices are firm. The easier position in tin has been reflected in lower price quotations and dealers anticipate a still lower level in the near future. Local prices have declined to 95 cents per pound. The lead situation has taken on a more acute tone in the States, and as a consequence the market here has been affected; no American lead can be shipped to Canada at present and this may shortly result in a stronger market here. At present the demand here is not excessive and the prices remain firm.

Spelter demand is very quiet just now and the situation is easier but as yet price quotations are unchanged. These remain at 10¾c per pound. Through a printer's error the Montreal quotation for spelter last week read 16¾; this should have been 10¾c.

Heavier Tools Hard to Obtain

Machine tool requirements are still of sufficient volume to maintain the interest of dealers but the possibility of acquiring certain equipment is evidently as remote as ever. One dealer here states that it is next to impossible to secure equipment from the States, particularly lathes of a size greater than 25 inch. Where it is possible to place orders for machinery of the standard type nothing like prompt delivery can be obtained, as shipment cannot be guaranteed under six or eight months, and in some cases even longer. One dealer here had a testing machine recently, and while negotiating with the I. M. B. for its disposal, intimated that it would be difficult to obtain a similar machine from the manufacturers under three or four months. The official of the board replied that delivery could not be expected before a period of at least eight months.

In an effort to secure a greater volume of machine tools of a general character both those that are now on order and some additional equipment required for customers, another local dealer has left for the States to gather together as many tools as he can. If he can locate the same he is hopeful of securing permission to have them shipped through at an early date. Tools of a standard character are the hardest to obtain, this particularly applies to boring machines and milling machines. The recent placement of a large munitions contract here for the American government includes a shell of the 12 inch variety and considerable inquiry for suitable tools has recently been made to dealers.

Scrap Shows Little Activity

Dealings in old materials is not marked by any pronounced activity, and what market there is now left for the dealers is very quiet in character. The situation to-day is virtually in the hands of the government and the bulk of the business is done direct through the producer and the consumer with the aid of the Imperial Munitions Board. Considerable demand is still evident for machine cast iron and malleable scrap but the supply is apparently light and the market in this respect is quite strong. Old metals have weakened during the past week, but little more than a normal business is reported. New brass cuttings show a decline of ½c and are now quoted at $15 per hundred pounds. Red brass turnings show a similar decline and are now quoted at 18c per pound. Dealers are now asking 9c for light brass, this quotation being one cent lower than that of last week. Malleable scrap is comparatively scarce and quotations have advanced to $25 per ton, a rise of $4 during the week. Machine shop turnings have advanced from $8 to $9 per ton. Requirements for stove plate have become easier and the price is easier by $2 per ton, the current quotation being $30 per ton.

POINTS IN WEEK'S MARKETING NOTES

Coal miners have been on strike in Pictou County since September 16, and there seems small chance of them returning to work.

—

Makers of machine tools at many United States points are so far behind in deliveries that they are not looking now for any new business at all.

—

Dealers report that there is a fair amount of machinery scrap coming into the market now. There is a large surplus of brass and copper in the yards.

—

Some of the pig iron furnaces claim that at the new rate of price recognized by the government they are not making any money.

—

United States War Industrial Board wants the manufacture of phonographs to stop by the first of January by reason of the number of hands employed in that business.

—

More hopeful reports are handed out from Pittsburg regarding the steel supply. It is likely, on account of the number of non-essential lines that have been cut off, that the shortage of steel plate will be relieved.

WAR BOARD KEEPS KEEN EYE ON ORDERS

Dealers Believe That Plate Will Be In Greater Supply Before Long

TORONTO.—The securing of delivery of machines is one of the biggest matters that the machine tool trade has to deal with just now. It has been a serious item for some time, and the chances are that it will continue so. In fact there are a couple of cases in which considerable embarrassment is being caused because plants are not in a position to go ahead and produce shells, while at the same time they have to keep up a good-sized overhead charge against their plant. Dealers who can get machines can sell them if they can do war work, and it looks as though this condition would continue for some time to come. Some of the later contracts that are coming out now in the making of gas shells, which is largely foundry work, contain a cancellation clause, in case the war shall be done by a certain date, but, of course, the firms undertaking the work would be protected in case such a thing came to pass.

The Steel Trade

The War Board, at Ottawa, is getting to the stage where it can turn down orders and cut them pretty close in order to keep the allotment of steel coming to this country centred entirely on war work. For instance, one of the large public utilities of the province sent in an order for plate during the last week. It was returned to-day, and will not be filled. The plate was not for any specific purpose, but simply to keep up the warehouse stock for repair purposes. Canadian warehouses are getting quite generous shipments of material that is of the lighter gauge, but on material that comes within the scope of the Canadian allotment they are not receiving such generous treatment.

The Matter Of Price

There is quite a big gap between the prices at U. S. mills and the prices that are now recognized in Canada. The trade seems to think that if the governments of both countries stepped out of the way and allowed the steel situation to work out its own level there would be changes on both sides of the line. The Canadian market would be due to come down and the U. S. price might advance a bit. At present plate costs $7.50 at the mill, which is at the rate of $150 per ton. On this allow $10 for freight and handling and you have $160 plate in Toronto. The American price is $3.25 at the mills, which is $65 per ton. To this add $3 duty and $5 freight and it gives plate from the U. S. mill laid down here at $73, against the present Canadian price of $160. In competitive times this difference would have to be taken up quickly. The Canadian price would not have to meet the existing price in United States, for the trade seems to think that steel will find its level around $4 per hundred, which is a fair lift over the present set figure of $3.25.

Scrap Yards Full

Quotations for copper wire are off $1 this week. In fact all grades of copper scrap are weaker and are not moving as rapidly as usual. Previously all, or nearly all, the copper scrap used to be sent to United States points where it was used and turned back to No. 1 electrolytic copper, but now that there is an embargo against the shipment to that market there is a considerable quantity accumulating in this country, and as soon as stocks reach a certain size there is bound to be more or less reaction. Dealers claim that that stage has now been reached. The surplus stock of copper and brass of all kinds will increase if the embargo keeps up. The most of the copper scrap continues to come from the domestic utensils gathered by the country scouring of the metal wagons. Since the munitions business began to operate there has been a considerable amount coming from the bands, but the bulk of the matter that reaches the yards comes from the collectors all over the country.

There is also a fair amount of machinery scrap in the yards just now, which is quite a contrast from the conditions that have been general for some time past. In fact several of the dealers hinted at a lower figure for machinery scrap. There is enough on hand for the consumers to use now, and there seems to be very little tendency to buy very far ahead. There has been quite a lot of scrap coming from the west and other points.

PASSENGER AUTOS AND PHONOGRAPHS TO BE CUT OFF THE PRODUCTION LIST

Special to CANADIAN MACHINERY

PITTSBURGH, Pa., Oct. 2.—Through the combination of stimulating production and curtailing the supply of steel at all points to the actual needs of war activities, instead of looking to the creation of possible reserves, production and requirements may make a more even break at the end of the year than has been in prospect from the figures so frequently mentioned by the War Industries Board. First, early in July, the board placed the half year's requirements at 20,000,000 net tons of finished rolled steel, intimating that there was no likelihood of more than 16,500,000 tons being made. Later it increased its estimate of production to 17,000,000 tons, while by successive stages it advanced the requirements to 23,000,000 tons and then spoke of the possibility of 25,000,000 tons being made.

Production in the past three months has been fully 9,000,000 tons, and as the period included the hot weather, which always curtails output, while strenuous efforts are being made to increase production, the output in the next three months ought to be more than 10,000,000 tons rather than less. The September report of steel ingot production, which should be available within a fortnight, will give an inkling of the autumn pace in steel production.

Curtailing Steel Supplies

The War Industries Board has announced a large batch of steel curtailment arrangements made with various consumers, from the makers of clothes wringers to the makers of phonographs. On an average, the restriction during the last four months of the year is to be one-half the output in the corresponding period of 1917. It is desired that the manufacture of passenger automobiles and phonographs cease entirely January 1. Except in the case of a few items, not much steel, in point of tonnage, will be saved by this curtailment in industrial operations, but there will be a very important saving in man power. In the case of tin plate conservation, the work is being done by the Food Administration which has been making agreements with the packers of non-perishable food products to curtail their consumption of tin plate, or stop it altogether. As recently reported, a curtailment in tin plate production for the fourth quarter to 70 per cent of the former rate was ordered, but this conservation program is expected to make feasible a still greater reduction.

The War Industries Board, besides seeking agreements with ultimate consumers as to restriction in steel consumption, is also negotiating with the finished steel producers themselves, looking to a curtailment in their consumption of raw steel. The pipe mills, for instance, have been asked to consider whether a reduction in their output would cause difficulty in any important war activity.

A very important point in connection with all this steel conservation work is that it is not directed towards the saving of steel for the purpose of putting the steel into some particular product or channel of consumption. Except for the item of rails, it is not definitely shown that the supply of steel is distinctly short in any direction, at least with respect to any considerable tonnage. To illustrate this point, the case of shells may be taken. It is quite clear that there would be no desire to save steel at the expense of shells. Nevertheless, the supply of shell steel has been scrutinized, not on the basis of how many shells the prosecution of the war requires, but on the basis of how much shell steel the forge shops can actually work. Ship steel has also been studied. No statement has been made as to how much, if any, steel has been found that can be taken out of these programs, but it is hinted from Washington that a new and revised estimate of the half-year's steel requirements may be forthcoming.

Pig Iron Prices

No particular effort is made to disguise the fact that the revision of pig iron prices for the fourth quarter of the year was dictated entirely on grounds of expediency. Some furnaces were making little, if any, money and it was desired to relieve them. A general and large advance could not be considered, and a schedule was worked out which is not logical but which is perfectly practicable, and which gives an increased price to the furnaces that have had the highest costs. Eastern Pennsylvania is put on a Pittsburgh basis, while Tennessee and Virginia are put on the Birmingham basis. As Lake Superior ore was advanced 25 cents, basis prices were advanced, but only on basic and foundry, forge and Bessemer being left unchanged. The ore advance of 25 cents would mean about 45 cents increase per ton in the cost of making pig iron, and the grades that are advanced $1 a ton comprise about three-fourths of all the iron that is sold, being therefore equivalent to an average advance of about 75 cents, and giving a net advantage to the furnaces using Lake Superior ore of say 30 cents. Furnaces using local ores, which are not changed, get the benefit of the full pig iron advance. The additional advantages given by reason of the removed basing points amount to 75 cents to $1 in the case of Tennessee furnaces, perhaps $2 to $4 in the case of Virginia furnaces, and possibly $1 to $3 in the case of eastern furnaces. The lake front furnaces will sell f.o.b. furnace as formerly, and as pig iron required by Canada will doubtless be allotted to them, the only practical interest to Canada in the price revision is that basic and foundry iron will be $1 higher than formerly.

There are wider differentials for silicon irons, and this applies even to No. 1 foundry, which is now $1.25 above No. 2 instead of 50 cents, the dividing line being 2.25 per cent. silicon. Buffalo and eastern Pennsylvania No. 2X is above 2.25 per cent, while No. 2 plain is 1.75 to 2.25 cent.

Basic Eight-Hour Day

The iron and steel industry as a whole will adopt the "basic eight-hour day" which the Steel Corporation announced it would make effective in its plants October 1. There has been so much argument in the past year or more about "the basic eight-hour day," much of it ignorant, much of it selfish, and not a little of it decidedly intemperate, that it might be supposed the news that it is being adopted by the iron and steel industry is regarded as of tremendous importance. It is, however, nothing of the sort. The change does not make a ripple in the industry's affairs. Hours of labor are not affected. There is merely a little change in the payroll clerk's arithmetic. Formerly, when a man worked 12 hours, his pay for the day was 12 times the hourly wage rate. Now it will be 14 times. The ten-hour man will get 11 times the hour rate instead of 10 times, for the hours beyond eight are to be paid time and a half. One is a wage advance of 16 2/3 per cent, the other an advance of 10 per cent. Men working eight hours get no advance at all, by the new system, but a little advance may be given some of them. The total increase in payrolls will hardly average 10 per cent. This is the eighth wage advance since the war began, the first being on February 1, 1916. Six were of 10 per cent. while one was of 15 per cent. As to hours of labor being reduced, and the total volume of man power for making steel reduced, the plain fact is that the 12-hour men have wanted to work the 12 hours. When they are paid a bonus for the hours above eight, they will be still more anxious to work them.

BIG CONTRACTS OUT FOR SEMI-STEEL SHELL

U. S. Government Sends Out Call For 33 Million Gas Projectiles

Special to CANADIAN MACHINERY

NEW YORK, Oct. 3.—To carry out the impressive program of the War Department for a vigorous prosecution of the war, several hundred million dollars more must be spent in the purchase of machinery for the manufacture of guns and ammunition. The request recently made to Congress for a deficiency appropriation of $7,000,000,000 emphasizes the enormous work that must still be done in providing war material. The Ordnance Bureau alone will require several billion dollars for artillery and for shells of various kinds. Contracts are now being distributed for small arms and additional orders have been placed for semi-steel shells. For the 33,000,000 semi-steel shells required it is estimated that about 140,000 tons of pig iron and about 60,000 tons of steel scrap will be needed. In the last week orders for about 36,000 tons of malleable pig iron for such shells were placed and other large contracts are pending. It is the intention of the Ordnance Department to obtain the assistance of about 150 small foundries throughout the country to take on such work. Manufacturers are also being sought who can produce trench mortar shells of light type for carrying gas, smoke and illumination.

In the last week buying of machine tools in the eastern territory has been confined to small lots. In the interior buying has also been of relatively small lots but in the aggregate the volume of business has been heavy. Several large contracts for shop equipment are still pending, the largest inquiries coming from the Ordnance Department for the Neville Island gun and projectile plant being built by the United States Steel Corporation.

Some Big Deals

Purchases are now being made against a list of 318 cranes. The Midvale Steel & Ordnance Co. is about to put out a list of heavy tools required for equipping a 12-inch howitzer plant at Nicetown, now that purchases for the 16-inch howitzer plant have been completed. The Watervliet Arsenal has bought additional tools costing about $100,000. The General Ordnance Co., Derby, Conn., has purchased tools for manufacturing guns to equip hydro-airplanes. The Rock Island Arsenal is about to ask bids on $250.000 worth of forging and other shop equipment. The Kohler Co. has bought machines for making shells.

The Ordnance Bureau of the War Department has established a new division under the direction of Captain John Turner. formerly of New York, to supervise all ordnance equipment purchases and there is a possibility that all buying of machinery for ordnance contractors will be centered in Washington. The Bureau has also placed several additional contracts for light arms. The Burroughs Adding Machine Co. has taken a contract for pistols and two similar contracts are pending at Philadelphia. Several small manufacturers in the east are buying tools for making fuses and nozzles for flame throwers.

The General Engineer Depot in Washington has been buying machinery quite heavily for installation in locomotive round houses in France where a great deal of repair work is done. The Yale & Towne Manufacturing Co., Stamford, Conn., and the United Injector Co. of Boston, have purchased tools for making nozzles and injectors. The Towle Manufacturing Co., Newburyport, Mass., previously manufacturing silverware, has taken on a contract for gas buoys and parts of gas masks.

The Lake Torpedo Boat Co. has put out an inquiry for $300,000 worth of machine tools to increase output. The New York Shipbuilding Co. has given a contract to build a plate and angle shop to replace the buildings recently destroyed by fire, in which they sustained a loss of $300,000 but the company continues to operate full capacity, about 40 ships being under construction. At the shipyards being operated by Pusey & Jones hereafter only 12,000-ton ships will be built and the five shipways at Gloucester City are being combined into three large berths for the building of the larger type boats.

NEW PROCESS FOR SHELL NOSING

Canadian manufacturers are keeping to the front in the development of munition machinery of all kinds. A recent development being perfected at present promises to effect considerable improvement in the method of nosing in shells of all sizes. We are fortunate in securing data regarding this development and promise a valuable feature in the near future.

MAY CATCH TONNAGE BY THE FALL OF 1922

Chairman of Shipping Board Tells Something of the Work Being Done

Through the efforts of American shipbuilders the nations fighting Germany have broken "the backbone of the submarine campaign," Chairman Hurley of the Shipping Board said in an address before the Philadelphia Chamber of Commerce, opening the fourth Liberty Loan campaign. He predicted the national marine tonnage will be restored by the fall of 1922 or earlier.

"Every plan, every prediction, made by the German government has failed," Mr. Hurley said. "As the British fleet bottled the Germans in the Kiel Canal, as the brave French held the Germans at the Marne, the shipbuilders of America have dashed for ever the hope of Germany to isolate this country and prevent its participation in the war of humanity against despotic military power."

Allied Ships Made it Possible

Despite the enormous expansion of the shipbuilding industry, Mr. Hurley said, it had not been possible to provide the tonnage necessary to transport the American armies to France and maintain them there. Credit should be given, he asserted, to England, France and Italy, who though "short of ships themselves made further sacrifices in order that we might easily get nearly two million American soldiers to the battlefields in the first year and a half of our war against Germany.

"War has produced a community of interests among the Allies and America and it is only by the unselfishness of each that all can be assured of victory."

PICTOU COUNTY MINERS GO OUT ON STRIKE—A BAD SITUATION

Special to CANADIAN MACHINERY

SYDNEY, N. S., Sept. 30.—The coal-miners of Pictou County have been on strike since the 16th September and at the time of writing there is no likelihood of them returning to work. The action of the miners is incomprehensible and indefensible, inasmuch as it is in direct contravention of the agreement with the operators. Following the lead of the Cape Breton miners—who are organized in the Amalgamated Mine Workers of Nova Scotia—the Pictou miners—who are members of the American Federation of Labor—agreed to a wage adjustment in the spring, subject to review at the 1st of July to conform with any appreciable increase which might in the meantime have taken place in the cost of living. In Cape Breton, after some negotiation, a figure of twenty cents per day was agreed upon as representing the amount required to compensate the men for the increases which had taken place, and a wage increase of this amount has been arranged. In the case of the Dominion Coal Company, certain additional adjustments were made as between the wages of the machine-runners and their helpers, which were intended to more equitably distribute the wages paid to these two classes of employees. In any case the agreement between the men and the companies in Cape Breton was loyally lived up to by both the men and the companies.

Sent Ultimatum

In Pictou County the operators offered the men the same increase as had been arranged in Cape Breton, but the men refused to consider this offer, entirely ignored the agreement with the operators, and issued an ultimatum that unless an increase was given of 15 per cent. to men receiving more than $3.50 per day, and 20 per cent to men receiving $3.50 or less per day, a strike would be called. The operators had little option. They are unable to raise the price of coal because of the restrictions imposed by the Fuel Controller, and to grant the demands of the men would have meant unprofitable operation of the collieries. The men refuse a Conciliation Board. They have so far ignored the instructions of the Fuel Director to return to work, they have violated both their agreement and the provisions of the Industrial Disputes Act, and apparently the authorities, notwithstanding all the special powers given to the Department of Labor and the Fuel Controller recently, are unable to bring the strike to an end.

Poor Timed Strike

A strike of any kind to-day is deplorable, but a strike of coal miners — in direct proportion to its extent—aids the enemy and hinders the war effort of the Allies. Individually, the miners of Pictou County are probably not lacking in patriotism. Their enlistment record stands to prove the contrary. They are not under-paid, and they have already lost far more in wages by idleness than they can make up in many months by any increases in wages they can hope to obtain. There is an economic limit to this matter of wages, and in the case of the Pictou coal companies this limit has been reached. Nothing can force a coal operator to persist in unprofitable operation of his properties. The only way out of the present deadlock is for the Government to take over and operate the collieries, which will mean saddling the Government with a monetary loss, and surely the Government has enough expenditure before it not to require such a proceeding.

A Grave Danger

The writer has on several occasions pointed out in these columns that a further reduction in the coal output of Nova Scotia seemed inevitable, owing to the reduction in the working forces, the entire cessation of immigration, the further operation of the Military Service Act the physical condition of the collieries, and the increasing costs of wages and materials; but no one seriously contemplated a strike of such an uncalled for and flagrant character as that now existing in Pictou County. The only explanation appears to be that the thinking and patriotic miners are all in France, and that the men who remain behind see an opportunity in the present great need of the Empire for coal to press their demands, which are dictated not by any economic pressure arising from low wages, but by a desire to squeeze out of the present national necessity all that the industry will stand. This attitude is, at least, understandable, but the practical repudiation by the men of their agreement admits of no explanation.

Must Have Coal

The production of coal is to-day the first of all military necessities. This statement admits of no qualification, but is the simple sincere expression of a fact. Coal mining to-day is not an industry, properly speaking. It is a branch of the military arm. The coal workers are soldiers, and should be so regarded. No excuses should pass muster for the idleness of a colliery to-day. It is far worse to have collieries idle than it is to have powder factories stopped, to have troopships tied up at the wharf, and to have reinforcements refused to our troops overseas. These things would not be allowed to happen without most strenuous efforts to prevent them occurring, but, unless coal is forthcoming, they must all happen eventually, and while it may be a long time getting there, the reflex of the Pictou County strike will eventually reach France and be represented there by a slowing up of the war effort of our country.

As Veterans See It

At a meeting of the Great War Veterans' Association held in Sydney recently the returned men spoke in no uncertain terms of the unpatriotic action of the Pictou miners, and if workmen will insist on calling such indefensible strikes, they must be prepared for a certain amount of bitter resentment from those who have learned by actual experience what it means to have ammunition and reinforcements delayed when they are supremely needed.

The public sympathises, and all true men sympathise with workmen fighting for their rights, with men who are oppressed and underpaid, but the coal workers in Pictou County cannot say that this is so with them, nor will they be able to defend with any hope of convincing the public a repudiation of their agreement. It is said that to-day every man should work or fight, but the Pictou miners are not working, and are thereby preventing other men from fighting. It is supposed to be a man's privilege to say whether he will work or not, but it is no man's privilege to-day to hinder the fighting effort of our armies. When he does that he is giving comfort to the King's enemies, he is helping the German, and no excuse will absolve either the men who do this, or the Government which permits it to continue.

PIG IRON PRODUCERS ARE NOT SATISFIED WITH DOLLAR BOOST

THE general feeling among the producers of pig iron at U S. points is that the advance of $1.00 per ton allowed by the War Industries Board, is not sufficient. They claim that this small allowance has already been more than absorbed by the increasing charges. The output of pig iron still keeps well in arrears of the demands that are made upon it. The situation at U. S. points is reported to be as follows:

Pittsburgh.—There is a feeling here that the Government now has secured almost perfect control over every situation that can arise in connection with the iron industry. As a result of this, few enquiries are made for material here, and those that are made are referred direct to Washington. Some increases are noted in the production of pig iron now on account of favorable weather and because a better quality of coke is being furnished to the furnaces.

New York.—Considerable tonnage has been lost here because there has not been enough labor to look after the work properly. There is also much speculation here owing to the fact that there seems to be a feeling that the extension of the draft ages may make further serious inroads upon the workers in the mills.

Buffalo.—One of the biggest furnaces in this district is sold up entirely for 1918 and is taking no business at all for next year on the theory that the Government is going to look after the sales.

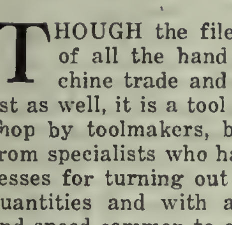
Making of Files Used to Be All-Hand Work

Interesting Features of an Important Piece of Work—Just Now the Securing of Material and the Making of Files is Proceeding Under Cramped Circumstances

By DONALD A. HAMPSON, Assoc. Mem. Am. Soc. M. E.

THOUGH the file is the most used of all the hand tools in the machine trade and is one of the oldest as well, it is a tool never made in the shop by toolmakers, but always bought from specialists who have developed processes for turning out files in enormous quantities and with all the uniformity and speed common to other lines of modern manufacturing. There are about a score of file factories on this side of the Atlantic—not very many—so it is not strange that most machinists have never seen a file made nor have followed the interesting steps in the process. In the early days of the business the work was all done by hand—the file was forged out on the anvil, the teeth were cut with a hand chisel and a hammer, and the file was hardened by heating in the forge fire and dipping into the tank at the side of the forge.

Naturally the results of this early day work could not compare with and could not be expected to compare with the files



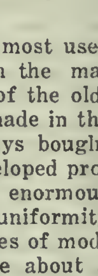


FIG. 1—CUTTING OFF BLANKS. FIG. 3—FILES PUNCHED FROM SHEETS.

which we can purchase so cheaply today. The early file maker taught his sons and kept the secrets of the trade in his family; these little file factories trained the apprentice, who later became the skilled workman in the plants which followed, a greater capital was needed and the demand for files increased. Machinery slowly came into use, and then, along in the seventies and eighties, and right up to this time the file business came in for its share of the attention and research through which the mechanical world has made such great strides.

In passing it is worthy of notice at this time when prohibition has come so much into actual and enforced being, that over-indulgence in liquors was one of the chief factors in the introduction

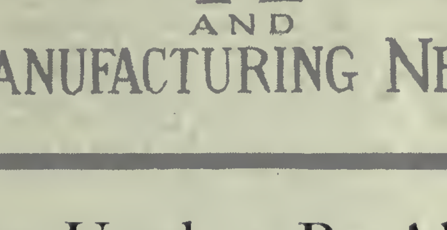

FIG. 2—SHEAR BLADES FOR FILE STOCK

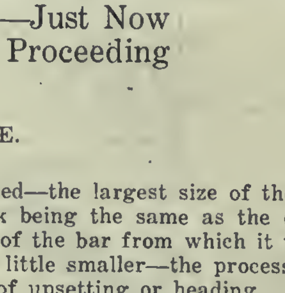
of machinery into the file making business. It has been said that file making was a closely held trade; the skill of these artisans was truly marvellous as we can appreciate when we compare the hand cut and machine cut teeth on so-called Swiss files—not one machinist in a hundred could do more than guess as to which is hand made. These file makers felt a true pride in their work; they thought they could not be superseded by any process, and being a well paid jolly lot, were wont to spend a day or two a week with boon companions in the vicinity of a friendly tavern, much to the exasperation of the worried shop owner who never caught up on his orders. At such junctures as this, the inventor with a new machine or process found a willing audience with the owner, who was only too glad to find a way to get along with a few less men or to substitute less skilled labor for that which was causing him his worries.

The Processes

"File steel" comes in bars of the right shape for all the types of files in common use, but to make the file thinner and narrower at the point, and to give the "belly" which is necessary to straight filing, the blank must be forged to size. The bar stock, which is a high carbon tool steel, is cut up and, and these shorter pieces drawn out and tangs formed—the largest size of the finished blank being the same as the cross section of the bar from which it was made or a little smaller—the process is never one of upsetting or heading.

Success in the file business to-day is gained by exactly the methods which have enabled other lines of metal working to meet competition and show a profit, i.e., attention to details and system. One of the paradoxes is the saving of money by doing an occasional extra operation (to make a subsequent one a quicker operation). To-day the size and shape of every file made is laid out on the drawing board and the standard maintained; there was a time when the plant's die maker established the standardard, and according as to whether he



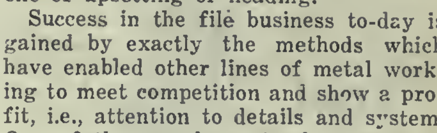


FIG. 4—ROLLING BLANKS. FIG. 6—SURFACE GRINDING.

modeled the new die after an old file or after a new idea of his own, the blanks looked like real tools or like clubs.

Waste, of course, is taboo. The bars of steel are cut off in shears the same as in machine shop practice. But there is a form of shear shown at A, Fig. 1, that is better adapted to file work than the usual type, which is shown at B. The shear at A cuts half way through the bar from each side, something (combined with the sharp jaws) that disturbs the grain of the steel less than the other method; then, too, the ends of the pieces have a double bevel such as would be put on the blank even if it did not come this way. The blanks should be cut off considerably shorter than the file-to-be to allow for the drawing out they get in forging; during the forging the belly and the tang are formed and the blank lengthens correspondingly. A few makers still do not "shape" the files enough—leave them too stubby—and while this makes the forging operation easy, it makes a poorer working file and is a waste of steel. By cutting the blanks short enough and drawing them

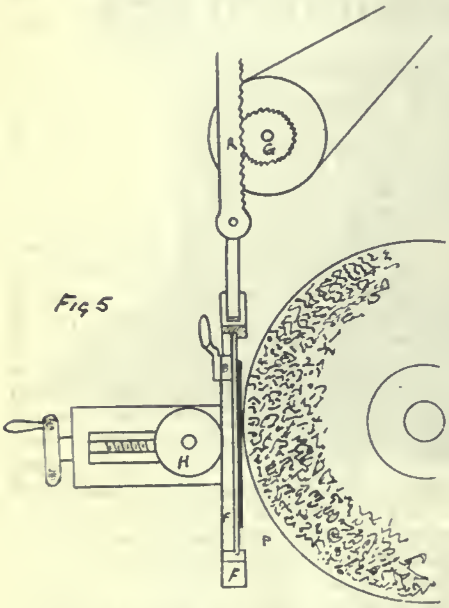

FIG. 5—GRINDING FLAT SIDES.

out more, not only will the file do more and straighter work in the hands of the user, but there will be a saving of steel amounting to from one to four more blanks cut from every bar.

In shearing blanks from the bar, dies are sometimes used for shapes other than rectangular. Round, square, and triangular shapes are cut with special dies with less crushing at the ends than when ordinary shears (as B, Fig. 1) are used for the purpose. Fig. 2 shows the lower members of sets for round and square bars. The upper member for three-cornered files is merely a straight blade, for square and round files, it is a duplicate of the lower one.

Forging

Forging, the succeeding operation, is one full of interest. Almost all the common machines for the purpose are used in forging files. The helve hammer, strap, spring, and drop hammer, all are used for different kinds of files. Drop forging is resorted to on half rounds and very thin files—work where the flash from ordinary die work is objectionable.

As has been said before, the shape of the dies has everything to do with the appearance of the files. File dies conform to regular form for shaping the edges, and in the center is the form for the broad working face of the file. Rounds are formed in a single pair of recesses. Tangs are forged at a separate heat and in separate dies. This gives the forger a free end to hold with his tongs. The furnaces are located close to the hammers so the forgers can sit before the latter and still be able to reach the red hot blanks. Furnace tenders load the files into the furnaces, and one such keeps several forgers supplied, thus allowing the latter to devote all their attention to the work where their skill counts for most. The forgers handle the files very rapidly, changing from side to side of the die, and finishing a file complete at one heat.

Two of the rectangular files—mill and warding—have a uniform thickness throughout their length. In sizes up to 8 inch they are now "forged" almost entirely by stamping on a punch press. Tangs included, they thus come out of the die ready to grind. Fig. 3 shows the general layout as these files are punched, though they are spaced somewhat closer together for economy of steel. The steel comes in sheets of thicknesses for each size of file.

Another most interesting variation of the forging process is "rolling." The machines used bear a resemblance to the two-high rolls of the steel mill. Fig. 4 is a diagram of the elements. The two rolls are geared together and driven so their line of tangency is moving toward the workman. The body of each roll is smaller in diameter than the working portion, or dies, and this opens a space during every revolution through which the file blank may be thrust against the stop S which is adjustable for different lengths. The dies are removable; they are made of carbon steel, though sometimes chilled iron is used for simple forms.

The working face of the dies is not concentric but changes, so that while the dies just grip the blank at the heel tight enough to drive it, they roll the blank thinner toward the point. By shifting the gears the point can be made thinner at will. Usually the dies have several impressions in their face so that as many sizes or shapes can be rolled without changing. The rolls are so driven that one of them has a slight movement in the direction of its axis which is for the purpose of forcing the metal into closer contract and counteracting spreading.

Rolling is particularly fast. So fast that often a furnace is placed on each side of the rolls. Roughly, rolling will produce three to four times as many files as a hammer. Tangs are rolled, usually by boys. A boy can roll as high as 600 doz. tangs a day, while a skilled forger would do but a fraction as many. In fact, the rolling machine was scoffed at until shops could not get production from the skilled forgers who were inclined to be independent as to output. Forging rolls are usually made with a breakdown at one side to assist in reducing the section on some shapes.

Annealing

After forging the blanks are annealed to relieve strains and to make them dead soft for cutting. The blanks are stacked in piles in the furnaces and heated to a full red, they are kept at that heat for from four to eight hours, then the heat is turned off and the furnace sealed, allowing the steel to cool off slowly, which takes (or should take) from thirty to forty hours. The differences in time stated are the natural differences resulting from various types of furnaces, the manner in which they are loaded, the size and shape of the files, and the particular shop processes.

Annealing is an exceedingly important

FIG. 7. OLD METHOD OF GRINDING ROUNDS

operation, the quality of the file being no better than its annealing. Too much heat injures the steel and too little produces a file with hard and soft spots as it is cut, followed by warping in the hardening. The old method of judging the temperature of the furnaces was by noting when the piles of files "got red"; after that point was reached the fire was continued for so many hours and then drawn, after which the files were allowed to cool down. Pyrometers have replaced eye methods in up to date practice, and files are annealed with the same accuracy and uniformity that gears are treated. Formerly the furnaces were heated with egg coal; this is expensive in first cost and for attendance and difficult to regulate to an exact temperature. Many coal furnaces have been rearranged for oil or gas fuel, and the result is a decreased fuel and labor charge, together with much closer regulation. When the gas used is free from sulphur the flame may be turned directly in the heating chamber with no injury to the file blanks, but when sulphur and certain other elements are present the muffle type of furnace is safer to employ —the cost of operation and time of heating being correspondingly greater. The

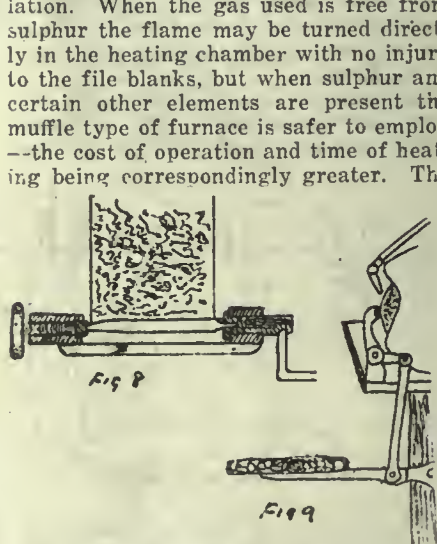

FIG. 8—FORM GRINDING ROUND FILES.
FIG. 9—GRINDING ROUNDS.

gas made from naptha is said to be the best for a direct flame.

The forge furnaces are subject to the same remarks in regards to fuel. The economy of a piped fuel supply over one that has to be trucked is obvious. With the proper kind of gas there will be very little scale left on the hammers and the annealed blanks wil have a minimum of scale to grind off. Economy of space and a clearer atmosphere are additional points in favor of gas and oil.

Grinding

Grinding follows the annealing. Its purpose is to remove the scale and to produce an even, smooth surface for the cutters. It is a well known fact that after a thorough annealing a piece of tool steel cannot be hardened on the untouched surface—in shop parlance, the carbon is burned off the surface. But if a hundredth of an inch is taken off that blackened outside, this new surface hardens at once. The provides one reason for grinding, and another is that in the heating and various handlings the surface may get slightly briused or the file may get a little bent. All this is removed in grinding. If a single black spot is left on then there will be a soft tooth.

Custom and precedence have fixed certain processes in the minds of file workers as standard. Nowhere have these "standards" been harder to eradicate than in the grinding department. To the old time file men grinding means natural grindstones, men dressed in leather to keep from being soaked all the time, men sitting in awkward positions astride the grindstones and working thus in a dim light caused by the windows being continually spattered up. In the file, saw, and cutlery industries such conditions are to-day frequently encountered—we who are familiar with grinding as done in machine shops all over the land where light and comfort and cleanliness are synonymous with the

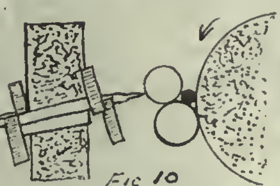

FIG. 10. ROUGH GRINDING ROUNDS

term "grinding" marvel at the resistance of workmen to changes.

Why artificial abrasive wheels—which we will here group as "emery wheels"—are not universally used, is very hard to say. With them suitable work holding fixtures so grinding is not a matter of skill but one of manufacturing uniformity should be provided. The emery wheels should be hooded as a matter of safety—likewise suitable splash plates ought to be a matter of course.

The grindstones still so prevalent are Ohio natural stones of 8 ft. diameter and about 1 ft. face. These cost somewhere around $35, and last two weeks; then it takes two men all day to change to a new one and the "machine" is idle all that time. For rounds and half rounds the grindstone is mounted on an arbor that rests in two heavy pillow blocks and is driven by a wide belt from the line shaft at the back of the room some fifteen or twenty feet away. Flat faces are ground on an interesting machine part of which is shown in Fig. 5. This uses the same grindstone, mounted and driven in the same way.

Referring to Fig. 5, a file is shown in heavy black. Several of these are held in a suitable fixture, or magazine, P, which is in the form of a plate that may be swung back and taken out when the locking bar is tilted back, released by the handle. The grinder runs more than one machine and fills these extra magazines while files are grinding. A yoke piece F is something like a picture frame; it serves as a container for the

FIG. 11. HALF ROUND GRINDING

magazines P, and has machined sides that travel vertically in the side castings of the machine (these not shown). A reciprocating motion is given to F by the rack R and pinion G which are driven from a countershaft and operate in the same manner as a planer shift to get the reverse. The length of the stroke may therefore be adjusted and a constant surface speed of the work maintained.

The rack and the frame are connected by a rod that permits of a limited flexibility so that thick and thin files can be ground. Pressure for grinding is obtained through a roller H set in a slide on each side of the machine, bearing against F, and adjusted by the hand wheel; these screws are connected by a cross shaft so as to act in unison.

The vertical travel of the grinder can be thrown in and out at will. Files can thus be removed or inspected without stopping the stone. In order to prevent the formation of grooves in the stone the latter is given a slow movement and return in the direction of the axis, the mvement being through a cam arranged at one end of the shaft. By this time the reader will have wondered how a (roughly) convex surface is ground by passing the work in a straight line at a tangent to the periphery of the grindstone; the principle employed is to let the work follow the stone and is obtained by using a rubber backing for the files as they rest in the rack or magazine P. The files thus move slightly in their seats, and if the machine is set to grind the point thickness the rubber compresses an amount equal to the difference as the body of the file is being ground.

A more mechanical and modern way is to have the runway for the rollers on the back of the frame F curved, making their surface parallel to that of the file and replacing the adjusting screws by heavy springs which put an even pressure on the grinding at all points. A stop is used to prevent too much grinding in case the operator neglects the machine for any reason. Screws are put back of the springs to regulate the pressure of grinding for different kinds of work and for files of different sizes. Of course this method is more expensive in the first cost for a set of runways, or bearers, must be provided for each shape of file, but the result is a uniform product; there is also a saving in rubber and the cost of renewal.

In file work, the taper of the tang is used to a great extent for holding purposes. The machine just described holds its load by setting one end of the files in a strip with taper slots, the hands grinder jams each file blank in a metal handle, and the cutter has a taper guide or holder on his machine to position the file as it is cut.

From a mechanical standpoint the grinder of Fig. 5 leaves but little to criticise. The production is high, the quality of the work first class, the wheel is well covered and supplied with plenty of water—a trough under the machine catching the surplus and very little spattering about. Water is used in all grinding on files. The grindstones do not glaze the surface of the steel if they have been well cared for, and this is one of the arguments in their favor—the soft, open face they leave on the work. But a stone that has been carelessly exposed to the elements for a length of time will become hard in whole or in part and will do inferior work.

Fig. 6 is a plan view of a surface grinder of the Blanchard or Pratt & Whitney type, arranged to grind flat sides of files. The emery whell is marked "W." On the table of the grinder is mounted a false table P for holding two loads of file blanks. The operator empties and loads at the free end while the load at the other end is being ground. The table P swivels through 180° and locks, which makes an

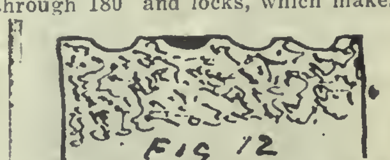

FIG. 12. FORM GRINDING HALF ROUNDS

arrangement that reduces the idle time of the machine to a minimum and keeps the operator fairly busy. Here also are shown the taper notches by which the file is held at the tang—at the other end pins take the side thrust of grinding The production is equal to the other type of grinder; other advantages are the ease and comfort with which the grinder works (and consequently he is better satisfied) and the few minutes only that it takes to change the wheels.

Emery wheels properly selected will do better and faster work than the grindstones. The prejudice against them comes from the hard surface which they leave on a piece of steel—when any old wheel is used at any old speed—as contrasted with the open surface from the grindstones, which come uniformly too soft (often many grades too soft).

Adapting the wheel to the work permits the grinder to produce as nice a surface with the manufactured article and that grit and grade once determined can be reproduced in one of a thousand duplicates. It might be noted in passing that German shops discarded the natural wheels many years ago.

Magnetic chucks have been tried on surface grinders for holding file blanks to be ground, but owing to the first cost of chucks that fit the shape of the blank, very little progress has been made, though the scheme has shown itself to be rapid and practical. Milling of the broad faces of mill and warding files is also done—fixtures of a type that holds several files at once are employed, and where files are large and have much stock to come off the method is preferred to grinding.

Rounds have always been the bugbear of the files business—there is so much hand grinding on them and they require so many more cuts than any other file that there is no money in them, and makers consider them a product to be endured to hold their customers. The time-honored way of grinding rounds is for a man all dressed in leather to sit above one of the grindstones on a "seat," whose real function is to deliver the grinder's weight to the hook shown in Fig. 7, encircling a round file. The grinder thrusts the tang in a metal handle, raises his weight so he can slide the file under the hook, and then sits down to work, turning the file and moving it lengthways to grind over all of the surface. The work is done rapidly, considering the mud and discomfort, but the product can hardly be expected to be uniform. An inspector watching one of these men at work remarked, "That is the least desirable of all the factory jobs I have seen in my career."

Some plants have adopted more modern methods for round grinding. Emery wheels have replaced the grindstones and, whether they have or not, the working position has been changed to the front of the wheel where the grinder can produce in comfort. That a position astride the wheel is not necessary to utilizing the grinder's weight is shown by the most successful arrangement in Fig. 9. Here a fork is connected by levers to the seat, water in plenty is supplied but splash plates keep it on the work. The workman turns the file by hand as before, using a handle for his grip.

As file grinding passed out of the realm of rough work, form grinding came in. Fig. 8 shows an arrangement successfully used to form grind rounds—used with the natural grindstones. The face of the stone is dressed to concave shape by a dresser travelling in a fixture. A swinging bar B has centers in each end to hold round files, with a screw center for tightening and for removing the finished pieces. This bar is brought up until the file touches the wheel, then the handle is turned and the file ground the full length as it is turned. This makes a file of uniform shape and does it in the shortest time. Those familiar with form grinding will wonder why this was never attempted before; the reason is that first custom had to be upset, then the entire standard of the work had to be raised to where the thousands of blanks would come to the grinder so uniform that it was possible to do this operation in commercial time, once the new system was all in operation, the cost dropped and the quality improved.

The rig shown in Fig. 8 is used for several sizes of files without changing the face of the stone. Good rigid fixtures are required and the stone should be tested in practice to determine its nt grade for the work. A similar outfit is used for grinding the backs of half rounds but here the file is turned through an arc of approximately 120° and then turned back, repeating until the surface is clean. Because of the partial surface thus presented a longer handle is necessary than for the continuous rounds. It is understood that such grinding is just upon the straight section of the half round back—the bellied or tapering portion is hand ground.

Fig. 10 shows an interesting grinding operation on round files. Two rollers are mounted on each side of the emery wheel, set staggered to bring their centers closer together without a reduction of diameter. These rollers take the place of a V for supporting and pressing the files as they are ground; the friction is less with rollers than with a plain rest. The axe of the rollers are inclined to that of the wheel though not as much as is shown (shown increased for clearness of illustration). The files are fed in at the right hand side and by the inclination carry themselves past the wheel and out on the left. This device is used for rough grinding and is a great producer; the work produced is equal to the poorer class of hand grinding but it is done in a quarter of the time. The blanks are finished on another machine. The rollers shown are carried in a cradle which is pivoted and pressed against the wheel by heavy springs. Limit stops are provided.

The curvature on the back of half rounds varies on the same file from a radius of ¾ in. to 1½ in., from this it will be seen that any form grinding or travel in a fixed path is impossible for finishing the entire back. That portion of the back which is of fixed radius is ground very successfully on machines such as shown in Fig. 5, the only changes being the disconnecting of the cross movement of the grindstone and the formation of proper radius grooves in the stone, one groove for each file in the rack. Fig. 12 illustrates this in part. Round files are also ground in the same way. After all the stock has been removed on the straight section, the tapering end must be hand finished.

An experimental device has been built to grind the entire back of half rounds on this same machine. The arrangement is shown at Fig. 11. The frame F corresponds to the same part in Fig. 5—it is hooked to the overhead arm to get its vertical movement, just as the other, and locked in place by the bar B. But instead of being held stationary the files are stuck into sockets which are connected with the gears G and their upper ends rest against a plate which is spring supported. In this plate are two pins for each file to keep it confined sideways. The gears are controlled by a rack D which is operated on by a ratchet motion at the bottom of the stroke and so given a movement that turns the file for each stroke, returning when the limit is reached. The device is intended to duplicate the result if the file were traveled lengthways across the face of a wheel and bids fair to working out to a commercial success. The file by spring tension is given a change to let its own shape guide it and remove the same amount from all parts. The pressure of the spring is not as great as used for flat grinding work.

(To be continued)

WOMEN AND MUNITIONS

The immense demand upon the resources of the engineering industry for the production of munitions of war has necessitated many changes in our industrial system in order to ensure the most advantageous employment of labor and material. A great expansion of productive capacity had to be brought about, and while, thanks to the navy the supply of raw materials proved no insuperable difficulty, the provision of the necessary labor to utilize those materials was a question which could not be solved so readily. The number of highly skilled craftsmen in the country was limited, and as such men cannot be improvised, it was essential to utilize their abilities in the most efficient manner, and to drawn upon the general labor resources of the country for all work which could be carried on without the lengthy and specialized training of the all round tradesman.

The wide employment of women in engineering works and the engineering sense and capability that they have developed is undoubtedly one of the outstanding phenomena of the war. Not that there is anything new in the employment of women on engineering and allied work, for it is recorded that half a century ago a firm in Birmingham employed at one time 2,000 women in its works. Generally speaking, however, their female labor was confined to rough and poorly-paid industries, such as the chain, nut and bolt, screw and rivet, and the small metal trades generally, though later women began to take a more intelligent part in the newer industries such as telephone and other instrument making, electrical work, cycles and motors.

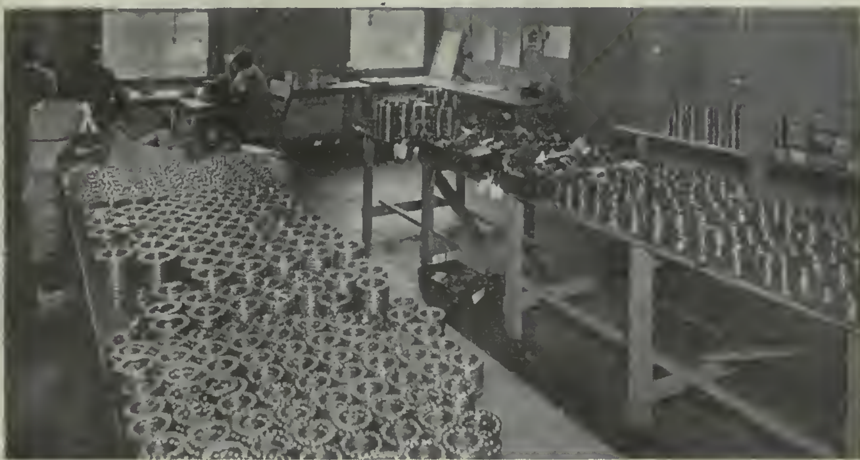
Usually their more advanced work was confined to the operation of automatic and semi-automatic tools such as capstans, presses, drills, screw and gear-cutting machines producing repetition work and requiring little more than manipulative dexterity, though there were a few women in isolated shops doing skilled work on the centre lathe and at the fitting bench; indeed in the works of a prominent member of this institution women were employed on fitting work using micrometers and working to a half-thousandth of an inch, but this was an exceptional case.

War Calls For Great Ball Bearing Production

Demand For This Fitting in Aeroplanes and Motor Trucks Has Been Phenomenal—The Canadian Firm Has Opened up Factories in the States as Well

By T. H. FENNER, Associate Editor

AN industry which was well established and organized before the war was thought of, but has had enormously greater demands thrown on it by the war, is that of making roller bearings. The widespread use of motor traction in all departments of the armies in the field, and behind the armies, and the extensive use of ball bearings in every type of motor, has necessitated the production of thousands, where hundreds sufficed before. Canada is doing her share in supplying this demand, and the plant of the Chapman Double Ball-Bearing Co., Toronto, forms a notable instance. This company has been manufacturing ball-bearings for many years, and their product is well and favorably known in hundreds of industrial plants, so they were well equipped with both the mechanical appliances and the organization to deal with the requirements of the British government in making annular and thrust ball-bearings for automobiles, trucks, and aeroplanes, which work they are chiefly engaged on now, together with the manufacture of shells.



FINAL INSPECTING AND ASSEMBLING ROOM

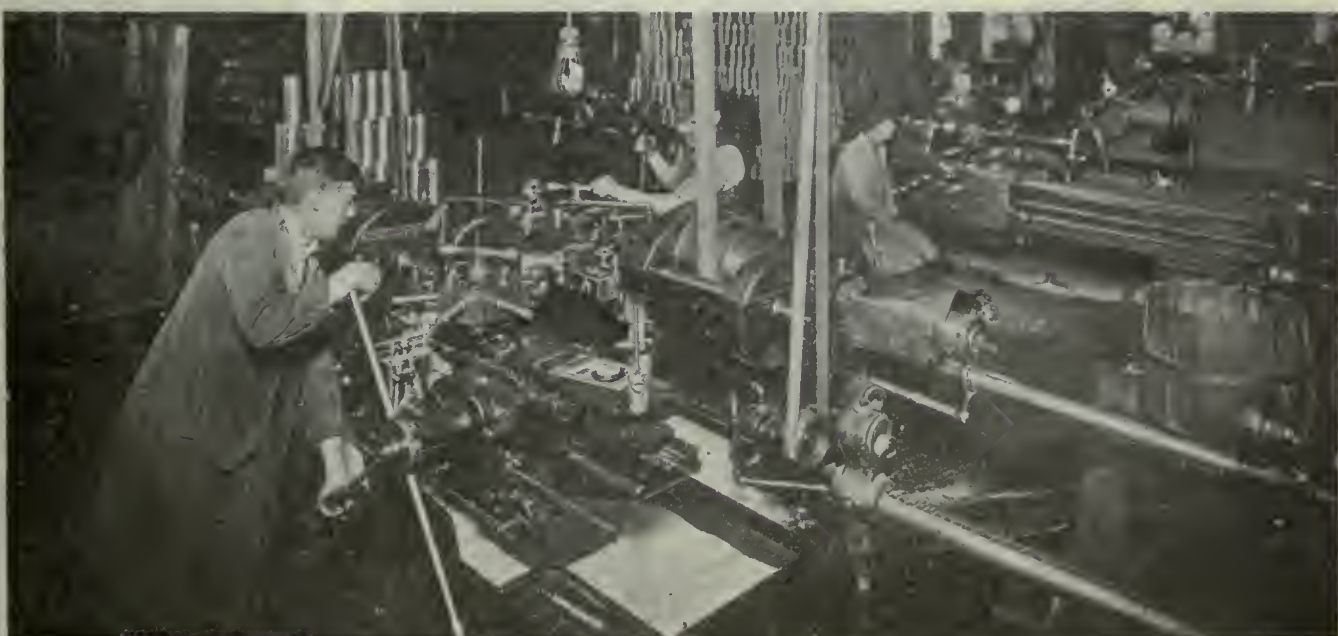
The Annular Ball Bearing

The annular ball bearing consists essentially of three distinct parts, consisting of the outer race, the inner race, and the balls and cage. The outer and inner race are formed from one steel blank, the inner race being cut out of the blanks by a trepanning operation. The first operation on the blank is that of boring the hole on a Colborne vertical boring machine, allowance being made for the subsequent boring and grinding to the finished size. The blank then goes to a Foster hollow spindle turret lathe, of which there are six, shown in the accompanying illustration, and here they are faced on both sides. The next operation is that of trepanning, also performed in the Foster lathe. In this operation a trepanning cut is taken from one side half way through the blank, which is then turned round and cut through from the other face to meet the first cut. The inner and outer races are thus formed in the rough, and are now ready for the initial heat treatment.

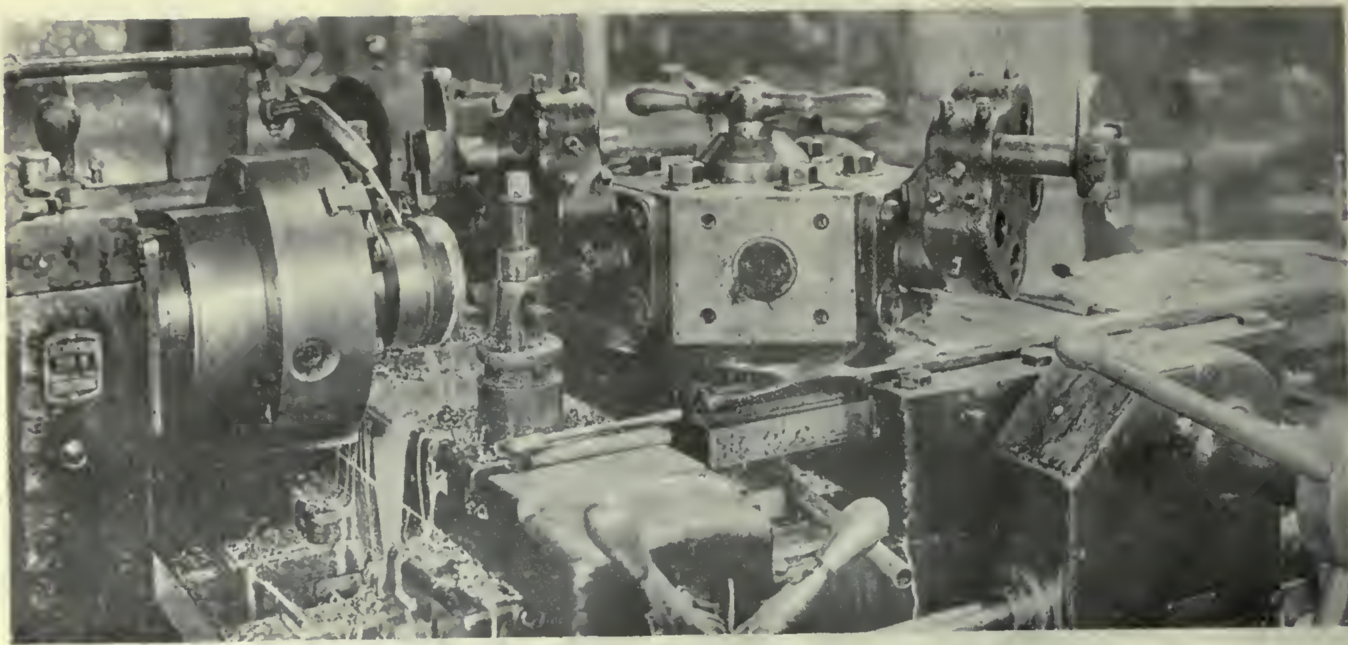
Initial Heat Treatment

The initial heat treatment is carried out in oil burning furnaces, and consists in a gradual heating up to a temperature of about 1375° Fahr. When this temperature is reached they are removed from the furnace and allowed to cool down naturally to the atmospheric temperature, this treatment relieving the metal from the initial stresses set up in forging the blanks. From here the partially formed bearing goes back to the Foster lathes to have the finish turning operations performed on them.

It may be stated here in passing that were it possible to procure steel tubing of the necessary tensile strength and



FOSTER TURRET LATHE TURNING OUTER RACE



FOSTER TURRET LATHES TURNING BALL RACE

chemical composition, a good many operations could be dispensed with. However, it is impossible to procure this tubing at the present day as the demand is far ahead of the supply. A great deal of this tubing used to be obtainable from Germany, but needless to say this avenue is now completely closed.

Finish Turning Operations

The outer race is first placed on a mandrel, and the outside diameter turned up to size ready for grinding. It is then taken off the mandrel and placed in a chuck, and the ball race turned up. The same procedure is followed with the inner race and the next operation is making the slot for entering the balls. The use of this slot makes the entering of the balls into the race considerably easier, and allows for the use of more balls. Incidentally it was the cause of litigation reaching to the Supreme Court of the U. S. The original patent covered an absolutely uninterrupted ball race, and the patentees contended that the inserting slot was a break in the continuity. However, it was shown that the slot was not carried down to the bottom of the race but was left .001 in. higher, thus not interfering with the ball race proper. It can be easily understood that entering the balls without the slot was a difficult operation, as after a certain number of balls were in place the inner and outer race would assume a position slightly eccentric to each other, making the springing in of the last balls a very difficult operation. The use of the slot does away with this difficulty and allows the ball race to be completely filled. After the inserting slot has been made the inner and outer races are stamped with the firm's name and the number of the bearing, and are then hardened. Between each of the preceding operations a preliminary inspection has been made, ensuring that all parts will finish up to size in the grinding operations.

BRYANT CHUCKING GRINDER

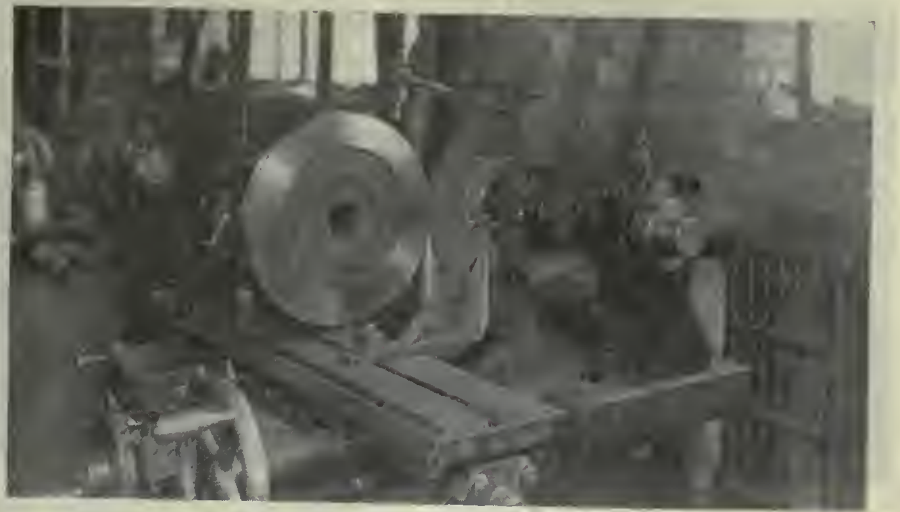
Hardening

The hardening of the races is a part of the manufacturing that has occasioned a great deal of experimentation, and the details of which are carefully guarded by the various manufacturers of ball bearings. The life of the bearing depends on the hardening and the grinding, and it is an open question as to which of these important operations is most influential, some makers favoring the hardening and others the grinding. It is easy to appreciate how much either of these operations can affect the finished product, but where experts differ it is outside of the layman to offer an opinion.

Grinding the Bearings

The grinding is carried out in two stages, rough grinding and finished grinding. In between these two stages a period is allowed for seasoning or what might be called a natural normalizing. This is really a period of rest to correct any fatigue or slight distortion which may have occurred during the rough grinding and is allowed to extend, whenever possible, over several weeks, but when production demands are too great for this, artificial seasoning is resorted to. The grinding operations proper are as follows: First, facing off the rings, which is done in a Blanchard surface grinder, with a magnetic chuck, an illustration of which is here given. The outer rings after facing are placed in a Bryant chucking machine and rough ground in bore, this machcine being shown in the illustration. They are then placed on an arbor in groups according to size and rough ground on outside. They are then chucked on Van Normand and Landis grinders and the race is rough ground.

The inner rings, after facing, are placed on a short steel arbor and the ball race is rough ground on machines made specially for this purpose, from the Chapman Double Ball Bearing Co's own design. Experiments have been made of grinding the race on these rings by placing them on expanding arbors, but the method now used has proven the best. Rough grinding the bore is done in the Bryant chucking grinder and then they are put away for seasoning. A very important part of all these operations is to make sure of perfect cleanliness between each, and great care is taken to ensure that this is done. The finished grinding operations follow the same course as the rough grinding. Grinding the ball slot is a most important phase of the finished grinding.



CHAPMAN BALL BEARING CO.'S GRINDERS

Inspection

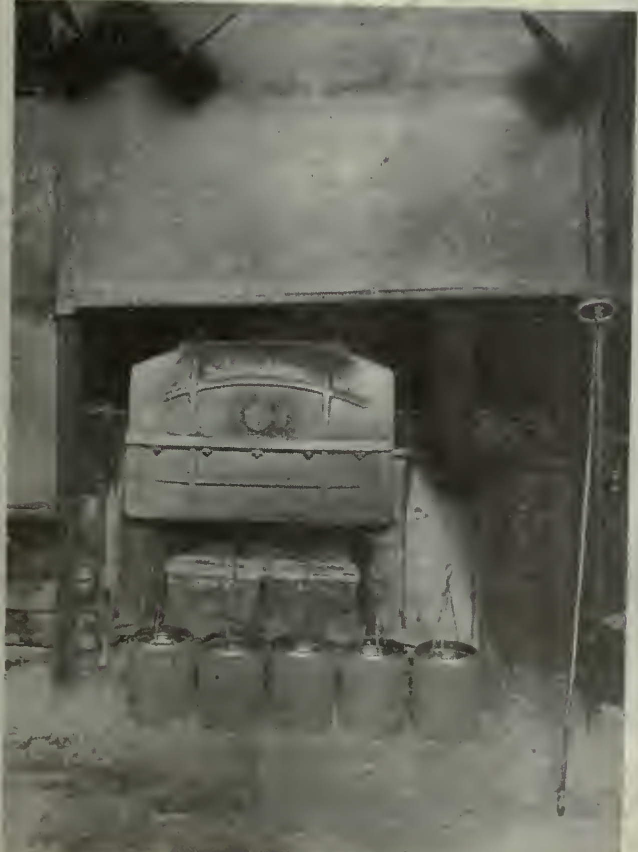
The necessity of a rigid inspection can be readily understood when it is explained that the greatest toleration allowed in any part is .0004 of an inch, and in the case of the race diameters no toleration at all is allowed. Much care and experimenting has been expended in perfecting this department, and large sums have been spent in procuring absolutely reliable measuring instruments. Among these the Prestwich fluid measuring gauges are prominent, and a complete set of standard Johannson blocks are used for checking the working limit gauges. By the use of these up-to-date methods absolute uniformity and interchangeability are procured. To ensure that no damage or rusting can take place during shipment each set of bearings is wrapped in oiled paper and enclosed in a metal case.

The Thrust Bearings

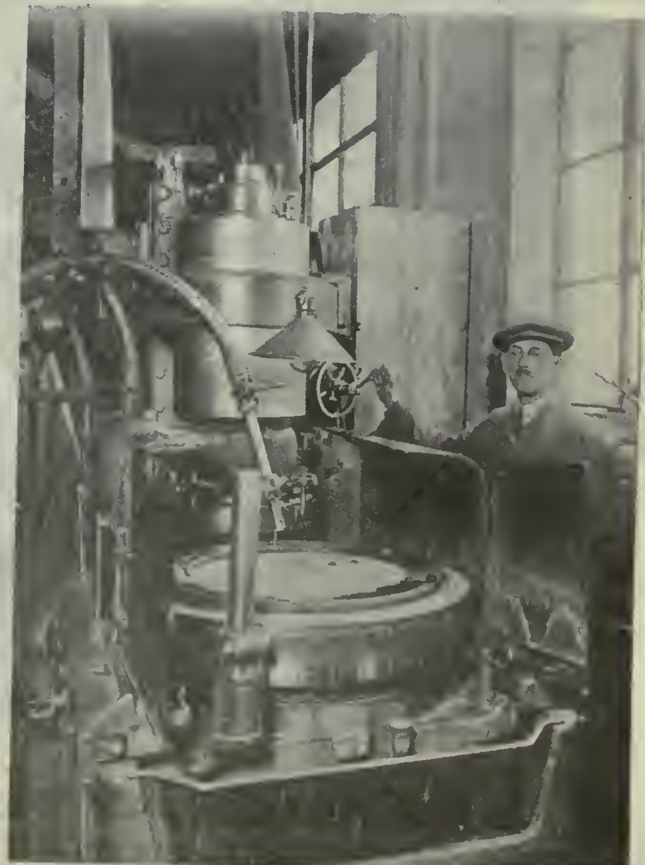
The thrust bearings are made from blanks punched out of strip steel, these blanks being then indented for the ball race. They are then bored and placed on mandrils for turning. They are afterwards hardened, and the subsequent grinding operations consist of grinding the faces, grinding the bore, grinding outside, and then the ball race, which are performed in the machines already described. The ball cage consists of a phosphor bronzs disc, and the holes for the balls are drilled alternately from each face. This method ensures that the weight of the thrust will always come on the balls and not on the cage.

The Organization

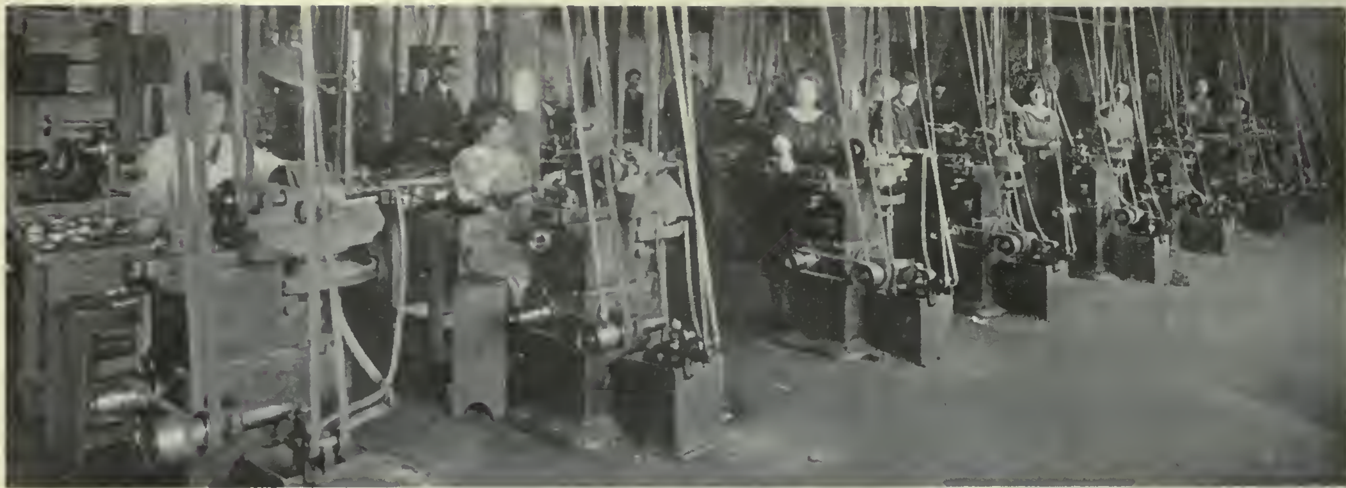
The making of these bearings is a class of work that calls for intelligent and skilled help. This has naturally called for a considerable amount of thought and selection in building up an organization, and has not been all smooth sailing in these days of shortage of labor. Female labor has been employed with considerable success, especially in the inspection departments. The mechanical end of the



OIL FURNACE FOR INITIAL HEAT TREATMENT



BLANCHARD SURFACE GRINDER WITH MAGNETIC CHUCK



VAN NORMAN GRINDERS

business is under the supervision of Mr. W. J. McCallum who has been with the firm for eleven years, for some time as head designer. Mr. McCallum is one of the inventors of the Chapman elevating transfer truck, which is very extensively used in munition and industrial plants. It is chiefly to his courtesy the procuring of the material for this article is due.

STANDARDIZATION IN GAUGE MANUFACTURE

The attainment of a high manufacturing efficiency is very difficult when the energies and interests of a firm are spread over the production of different kinds of products, unless the output of each product is sufficient to justify a separate department, machinery and staff for its manufacture. It cannot be turned out as quickly, cheaply, or with so great a percentage of female labor as it would be under conditions of proper repetition manufacturing, and in the national interest, therefore, firms should be confined as far as possible to the manufacture of the minimum number of different articles. This applies particularly to the case of gauges, cutters, small tools, etc., which in the aggregate absorb a vast and needless amount of highly skilled labor when manufactured in small quantities by firms for their own use. In the interests of the conservation of skilled labor it would be well if all standard tools and gauges required for munition work were manufactured as repetition products in factories set apart for the purpose. In a word, the production of gauges and small tools of all description should be placed on the same basis as that of shells, fuses, or other direct munitions the actual figures of the attainments in each respect of the best firms. But in order to determine the highest practicable standard for any given product more information is required. It is necessary to analyze methods of manufacture down to the smallest details, and to consider every operation in turn both from the point of view of the labor hours involved and of the class of labor necessary to perform it. Such an analysis is no doubt made now in greater or less detail by every firm when planning methods of manufacture, but the author holds strongly that for all munition products the Government should supply such information to contractors. It would avoid all controversy about the possibility of attaining either the efficiency standard or the dilution standard required by the Government, because the possibility could be proved by actual performance. Compulsory adoption of the standardized methods of manufacture is not advocated where firms can produce equally good results by any other methods. But the standard established would assist them in planning work and complying with the Government's requirements as to the maxima of time and labor permissible for a given output. The first objection which will arise in the minds of critics is that all firms are not equally well equipped for production, and that it would therefore be unfair to insist upon the standards of time and labor being universally adhered to. The proposal, however, would have the effect of preventing firms obtaining contracts they are unable to carry out efficiently, and this would obviate the waste of material and labor which now exists. Furthermore, it would justify the application of a firm for such machine tools as would enable it to carry out its contract in the most efficient manner, and would, therefore, rapidly bring about the proper equipment of manufacturing firms for their special products. It would also have a good effect in the standardizing of the best machine tools with a corresponding increase in the number available of the best types.

CONCRETE BASE CAST AROUND BASE OF GRINDING TOOL TO GET RIGIDITY

German Submarine; Its Detection and Destruction

Construction, Operation, Equipment, Methods of Detection, Means of Destruction—Various Proposals Considered

THE bulk of the war's inventions have originated with those who have had a grounding in the sciences or who have been well versed in machine shop practice or in other engineering pursuits. Many impracticable and even ludicrous ideas have been put forward by those who, having the best intentions in the world, were not sufficiently acquainted with the subject to plan intelligently.

In releasing information as to what has been done towards the elimination of the submarine, the Naval Consulting Board of the United States are performing a service which must necessarily awaken interest in those who have the skill to suggest improvements along the lines suggested.

No proposal which involves premises not based on the laws of nature as commonly understood is entitled to be recommended for experiment and development unless the inventor can show that there is a possibility of such laws being erroneous. Many proposals which depend for their operation upon effects which are contrary to natural laws as known have been submitted. Below is given an outline of some of the most popular misconceptions.

Electro-Magnets

Although the laws governing the use of electro-magnets are generally known and applied in a practical manner in a multitude of devices in common use, even the man of wise experience will be astonished at the limited range of their effect. For instance, the magnets used in our manufacturing plants, for lifting heavy masses of iron or steel are designed to exercise maximum magnetic effect, and for operation require a very considerable amount of electrical energy; yet a magnet which can lift twenty tons when placed in contact with an iron plate of that weight will not lift two pounds of iron or steel if separated from it a distance of two feet. Therefore proposed devices which depend on the attractive power of magnets for their operation in deflecting or arresting torpedoes, mines or submarines, must be governed by the simple laws of magnetism. A torpedo weighing approximately 2,500 pounds and traveling at a speed of from 25 to 45 miles an hour, will not be deflected to any considerable degree by any known application of magnetism, and it is not believed that an enemy torpedo, mine or submarine will ever be found in a position to be interfered with effectively by any electro-magnetic means, however powerful.

Detection by Magnetic Needle

Tests made on an actual submarine have shown that the magnetic effects due to this mass of iron, are quite limited in range. For instance at 150 feet distance the magnetic effect due to a submarine is only about 1 per cent. as much as the earth's magnetic effect. The submarine is equipped with a gyroscopic compass that cannot be affected by any magnetic influence from the outside.

Mine Attached by Magnets

A magnet deriving its power from any battery that could be contained within a bomb would not be powerful enough to hold the bomb in contact with a boat running through the water; therefore the scheme is impracticable. The main point would be to locate the submarine. When the submarine is once located very simple methods of disposing of it are at hand.

Electrical Effects

There is a general misconception regarding the electrification of water and the atmosphere. There is no known method of charging the sea with electricity; of shooting a bomb of electricity, or of charging the atmosphere with electrocuting currents. Suggestions along these lines should show that the writer has made research in the laws governing the application of electrical energy, and should contain sufficient proof of their feasibilty to insure serious consideration.

On the other hand applications of the transmission of electrical energy by means of alternating or pulsating currents—as used in wireless systems, for example—belong to a different class of electrical development. Inventive genius is rapidly improving apparatus of this type for the sending and receiving of signals and messages, and the possibility of valuable results in this field is unlimited.

The Submarine and its Operation

The first recorded experiment in submarine operation was made by a Hollander, Dr. Cornelius Van Drebbel, who in 1624 constructed a one-man submarine operated by feathering oars, which made a successful underwater trip from Westminster to Greenwich in the Thames.

Dr. David Bushnell, an American inventor and graduate of Yale in the class of 1755, nearly sank the "Eagle" in New York Harbor during the Revolutionary War by the use of his little one-man-powered submarine, the "American Turtle."

In England, the American inventor, Robert Fulton, in the presence of William Pitt, then Chancellor, and a large number of spectators, blew up a brig by exploding a mine which he had placed under her bottom by the use of his submarine boat. Both of these inventors were discouraged and were refused the necessary assistance to enable them to develop further their ideas regarding submarines, although they had undoubtedly shown that there were great possibilities in the underwater type of vessel

Modern Types

Modern submarines are divided into two general classes: the coast defense type of from 300 to 700 tons surface displacement, and the cruising type of from 800 to 2,500 tons displacement, having a radius of action of from 3,000 to 8,000 miles and capable of operating along the Atlantic coast of the United States from European bases.

Germany appears to be devoting her energy at present to the construction of a small group of a still larger type, reported to have a displacement of 2,800 tons, which also possess superior gun equipment for surface operations, greater speed when cruising on the surface, very much more habitable quarters for the crew, and storage capacity for a larger number of torpedoes and other supplies.

"One-Man" Type

Many hundreds of proposals have been received advocating one-man submarines and submarines of small size, to be manufactured in great numbers for the purpose of attacking and destroying the larger types of enemy submarines. This subject has been given exhaustive consideration and it has been conclusively proved that no small submarine can be provided with the necessary power, speed, equipment and living quarters for the crew to enable it to operate successfully in the submarine zone. Even the smallest of modern submarines requires a number of devices for its successful operation; an internal combustion engine, an electric motor—which also can be used as a generator to charge the storage batteries, water ballast and trimming tanks, pumps, air compressors, air storage tanks, torpedo tubes, storage space for torpedoes, quarters for crew, and other machinery and auxiliaries.

Hull Construction

Generally the German U-boat—which is the designation for the enemy ocean-going submarines—it made with a double hull. The bottom space between the inner and outer hulls is used for water ballast; the top space is used for carrying oil fuel. Water ballast displaces the fuel oil as it is consumed by the internal combustion engine.

The frequent statements that oil has been seen on the sea after a U-boat had been attacked may have merely indicated that the submarine's outer hull had been punctured. However, there is some oil slick on the surface when the exhaust mufflers are flooded.

According to recent statements, the conning tower, in the latest type of German submarine, is protected by a thin belt of armor plate, and the vital parts of the hull, which are exposed when operating on the surface, are also made heavier than the rest of the hull, to protect them at least from the smaller calibre guns.

Even if the periscope and conning tower are shot away the submarine may still be able to keep afloat and operate.

Source of Power

The internal combustion oil engine of the Diesel or semi-Diesel type is almost universally employed for surface operation in modern submarines, although much experimenting has been done with steam-driven craft, and many engineers believe that, for extremely high power, steam may yet be used effectively if some of the inherent disadvantages—excessive heat, etc.—can be overcome. The limit of practical size has almost been reached in the internal combustion engines used in the latest type of submarine, and if more power is needed the engines themselves will have to be improved, or, perhaps steam plants will be resorted to.

Owing to the fact that internal combustion engines require a great deal of air for their operation, which is not available when a boat is submerged, submarines must be equipped with an electric motor run by storage batteries for underwater propulsion. It is, therefore, necessary after the storage batteries are discharged by use, for the boat to come to the surface while its electric generating apparatus, driven by the internal combustion engine, recharges the batteries.

Speed

The speed of a submarine, like that of other vessels, depends upon the power of its engines or motors in overcoming the resistance of the hull to being driven through the water. For submerged operations the electric motor operates the propeller, the engine being uncoupled and the current for the motor supplied by the storage batteries. This electrical equipment, if it be of high power, occupies much space and is extremely heavy, especially if an extended submerged range of action at high speed is desired. Therefore, the space for such equipment on the underwater craft has to be provided by increasing the size of the craft. If high surface speed is also required, larger and heavier engines must be installed, which necessitate an additional increase in the size and displacement of the vessel Maximum surface and submerged speeds cannot both be had in one type of submarine, and therefore a compromise which gives the most efficient general results has to be effected. The main engines in a modern submarine constitute approximately 8 per cent. and the storage batteries 16 per cent. of the total weight of the boat. If greater surface speed is required the percentage of weight allotted to the engines is increased, or, if greater submerged speed the weight of batteries is increased and smaller engines installed. In general, submarines, to be capable of the highest possible speed both for surface and submerged operations, must necessarily be of the largest type, and many predictions of giant submarines are made.

German cruising submarines have a maximum speed of about 17 knots on the surface and 10 knots submerged.

Details of submarine construction are of less immediate importance than ways and means to protect surface vessels from submarine attack, but details of construction and of the many life-saving devices, such as detachable chambers or conning towers, and other mechanisms which have been proposed, experimented with and discarded, may be found in the references mentioned on a subsequent page.

Listening Devices

The submarine when submerged so that its periscope does not project above the water is blind, but not deaf, for it is provided with sound detectors or microphones that will indicate the approach and direction of a ship, if its own machinery is at rest or moving slowly, with noise so slight as not to interfere with the listening.

The propagation of sound through water is more rapid and efficient than through air, because water does not have so great a cushioning effect upon sound waves. While we speak of sound waves, and can measure their amplitude in some cases, there is no bodily displacement of the medium through which they travel. In general, the harder, denser and more incompressible the medium, the more efficient the transmission of the sound waves.

The underwater listening devices which are so frequently availed of in submarines and patrol boats and destroyers used to attack them consist primarily of a large diaphragm or its equivalent in some other physical form. The diaphragm is submerged and the pressure of the water upon it tends to cause it to deflect inwardly to a slight extent. When the sound wave strikes the diaphragm the deflection is increased and, when the wave has expended itself it is followed by a reduction of pressure which allows the diaphragm to recover until the succeeding wave strikes it.

The human ear can detect sounds having periods of vibration as low as 16 per second and as high as 30,000 or 40,000 in extreme cases, so that there is a very wide range of pitch over which listening devices might be used.

The vibrations emitted from a submarine are usually of low frequency and therefore the listening devices which are particularly designed for submarine detection have to specially adapted to low frequency, at the expense in many cases of their capacity for receiving the high frequency vibrations; whereas with submarine signaling devices designed to communicate from one vessel to another a frequency of several hundred vibrations per second is found to give better results.

In one typical form of listening device the diaphragm is provided with a telephone transmitter. The vibrations of the diaphragm vary the electrical resistance in the transmitter, which are either listened to by a telephone receiver directly or amplified by means of relays, such, for instance as the audion and other similar apparatus, which enables sounds to be heard which otherwise would be inaudible.

Ways and means to tune out extraneous noises, such as the falling of rain on the surface of the water, the noise of the pumps and other machinery on the boat carrying the listening device, and arrangements to determine the direction of the source of sound have been given a great deal of study and been developed to a considerable degree of effectiveness. Sound waves tend to emanate from the source radially, which is availed of in the direction-indicating devices. However, the details of these devices are more or less confidential, and only the great principles can be made available to the public.

Periscopes

The superior gunfire to be expected from a merchantman which has been properly equipped makes it prudent for the hostile submarine commander to obtain his observations for accurate aiming of the torpedo through a periscope.

A submarine is usually equipped with two or three periscopes, extending about twelve feet above the conning tower, the more recent periscopes being of the "housing" type, which permits them to be quickly raised and then drawn down after the observation, thus allowing the undersea boat to operate unseen much nearer the suface and not lose time in changing its depth of submergence.

It is rumored that the latest German U-boat has a short periscope "fair-water," which encloses the stuffing-box through which the periscope slides up and down. The periscope fair-water usually extends 4 or 5 feet above the top of the conning tower. The short periscope is used when the boat is moving at considerable speed through the water. An additional periscope, which can be extended to a height of from 14 to 16 feet above the periscope fair-water, is also provided. It is used only when the boat is stationary or nearly so. This taller periscope is used to reduce the chances of exposing the conning tower and hull of the submarine while patrolling in a rough sea, with the hull submerged. It is very small in diameter at the top and is commonly called the "finger" periscope. Owing to the vibration prevailing at any speed above four knots it cannot be used when a submarine is moving rapidly. A third periscope, smaller in diameter, is usually provided as a spare in case of accident to the two periscopes described above.

A periscope is usually designed to have about a 45° angle of horizontal field of vision, and the vertical field may be less. It is rotated by the observer in order to scan the whole horizon.

When a submarine is cruising on the surface the top of the periscope may ex- to a height of 23 or 24 feet above the water, thus giving a range of vision of about six miles to the horizon, if the day is bright; while an observer standing upon the conning tower can see the horizon at a range of only about four and one-half miles; however, the observer can usually see much more distinctly by his direct vision than through the periscope. The upper parts of ships can, of course often be seen beyond the horizon.

Greatly increased optical efficiency in the periscope is not a theoretical possibility, although various sizes and designs have been experimented with. Any increase of submerged diameter, or length of periscope impedes the submerged speed of the submarine. The older type gave a great deal of trouble from defective mechanical construction, but the more modern devices are hermetically sealed by the manufacturer and are reasonably free from condensation of moisture on the lenses and from vibration.

Experiments have been performed on the subject of decreasing the visibility of periscopes. It is very difficult to see a periscope, and the artistic use of paint, simulating foam and green water is one of the best means of making a periscope invisible. A periscope so painted, projecting a few feet above the water from a motionless submarine, can be seen at a very short range only, and if it is thrust up in quick observation and then withdrawn the presence of the submarine is usually not disclosed.

The use of mirrors has been suggested and experimented with, but the conclusion has been reached that their use is not practicable. Any rolling of the submarine will change the angle of incidence and reflection, and serve to reveal the position of the submarine.

Periscopes having their upper portions made of glass tubing to reduce the visibility have also been proposed.

It is, however, the wake of the periscope on a moving submarine rather than the periscope itself that attracts the attention of an observer.

Net-Cutting Devices, Etc.

Numerous devices and attachments have been provided to enable submarines to cut nets, put out divers, and to send a marking buoy to the surface in case of accident, and have proved more or less ineffective.

In manoeuvering it requires at least 60 feet—preferably 100 feet—depth of water to remain concealed and safe from gunfire, ramming, or collision with surface craft. Submarines are frequently tested for safe operation at depths of as much as 200 feet, at which depth few effective obstructions, trawls, or nets can be used against them.

A modern submarine may, if it is in good order and the hull not punctured, remain resting safely on the bottom for a day or more without inconvenience to the crew. Under favorable conditions, when the waters are less than 200 feet in depth, a submarine might lie at rest on the bottom and detect the approach of a vessel several miles away. In case the water is more than 200 feet in depth a submarine must usually be kept in motion to obtain steerage-way in order to hold its proper depth of submergence. This speed need not exceed one knot.

In its method of attack the submarine has many advantages over its adversary. The ship to be attacked presents a definite target of comparatively large size, and is easily seen by the submarine commander at a range where the submarine's periscope is usually quite invisible to those on the surface vessel. Even though the submarine be cruising on the surface it is not easily seen, because it has a very low freeboard.

As the submarine approaches an enemy's surface vessel it submerges, the periscope being the only evidence of its presence. Periscopic sighting of the target is necessary, as it has been found impossible to see through an underwater window far enough for practical observation. In the event of accident to the periscope a submarine must come to the surface for observation or else manoeuver blindly. If the sea be rough or the weather misty or foggy, the periscope may not be seen until its prey is destroyed by a torpedo, and in some cases not even then. The submarine commander thus has every opportunity to verify his adversary's identity, speed and course, also to decide upon the most vulnerable point of attack, and to place his boat in the best position to discharge an effective shot. Torpedoes may be discharged with equal effectiveness whether the submarine is on the surface or is submerged, but at the most effective range, say one half mile or less, the superior gunfire and greater accuracy of the guns of armed merchantmen and war vessels (because of their higher and steadier gun platforms) make the defeat of the submarine, operating on the surface, probable—in fact almost certain—if the torpedo attack is unsuccessful. A single effective shell might disable or sink the submarine because of its relatively small positive buoyancy, while the surface vessel might have many shells strike it and still remain in a seaworthy condition.

SAYS THAT THE BONUS PLAN OF WAGES HAS BEEN FAILURE

As an incentive in speeding-up production on war work, and at the same time with the idea of maintaining high standards of workmanship, many firms have adopted a bonus system in remunerating their mechanics. It is further felt that the plan would reduce to a minimum any feeling of restlessness among workmen and hence keep the organization intact. How is the plan working out? Most manufacturers have some interesting experiences to relate.

"I will say that the bonus system is a failure," said the head of one large eastern concern. "There is not a firm in Canada to-day that is paying better wages, or trying more seriously to be fair to their mechanics. Yet their attitude in these later days of the war suggests that if we can pay them so much under the bonus system, we can afford to pay it to them as regular wages.

"At first, the plan worked splendidly. But at that time, the men had not forgotten conditions under which they had worked prior to the war. Comparison was a simple matter—even to the simple minded. But now, they seem to have forgotten that a bonus is something they actually earn over and above their regular wages. They may earn their wages and they may not, but the bonus they must work for.

"In spite of this opportunity to make good money, there is still a lot of restlessness, still the petty distinctions made as between union and non-union men—even though wages be higher and conditions better than that required by the union. We have found in some cases that better work has been done by unskilled workmen than by the skilled mechanic who is getting high wages. We tested it out recently. A skilled mechanic was set to work on a certain job. At the end of the day he had produced six articles at a cost of $7. Then the work was placed in the hands of an unskilled workman and he actually turned out six an hour. I pointed out to the men that if we could afford to pay $7 for six articles we could afford to pay that unskilled workman at the rate of $50 a day. It is this indifference, this apparent unwillingness to speed up that is the trying proposition to the manufacturer.

"There is a great scarcity of skilled mechanics at the present time and it is deplorable that there should be a dog-in-the-manger, now-we-have-you-where-we-want-you feeling among any of the available men. Even where it exists in a very minute degree it is bound to retard production. Heaven knows that the manufacturer is not trying to take advantage of workmen. There are mechanics in our shop to-day who are actually receiving more than the superintendent. One of our bosses remarked recently upon the somewhat amusing fact that he was paid $150 a month for watching a number of men, some of whom were getting over $200.

"We have pointed out to men that the country is paying well for their services and that they should give the best that is in them. In many cases that fact does not stick. There are men and always will be men who recognize no responsibility, no allegiance toward their work or their employer and who feel that it is their privilege to make a bee line from one job to another at any time and without notice. It is most unsettling. I will say it is unpatriotic.

"It is of course, one of those regrettable conditions of war time. 'C'est la guerre,' the French say, but it would be delightful if all men recognized this duty in wartime. There is a time coming of course, which may impose something like normal conditions—but let all men recognize that the country is in this thing for victory and that every member of an organization should give the best that is in him."

Dividing Essential from Non-Essential Lines

How United States Authorities Have Listed the Industries so That War Contracts Shall Have the Preference—Four Classes and Various Divisions of Each Section

WM. BARUCH, chairman of the War Industries Board, has issued the new preference list of industries and plants, compiled by the Priorities Division of the board.

E. B. Parker, chairman of the Priorities Division, states that the determination of the relative importance of all industries and plants for both production and delivery by a single agency, the War Industries Board, renders it possible to maintain a well-balanced programme with respect to the several factors entering into production, which includes among other things plant facilities, fuel supply or electrical energy, labor and transportation, without all of which production is impossible.

Judge Parker says: "The administration of priorities is calculated to bring order out of chaos and to develop an evenly balanced industrial programme to meet the requirements of the military programme, and at the same time supply to essential requirements (as distinguished from the mere wants or desires) of the civilian population. Now that it is understood that priority and preference cannot be purchased the tendency is for prices to assume more nearly the normal level. It is now the public interest rather than the dollars of the purchaser that determines precedence in production and delivery."

An explanatory statement signed by Mr. Baruch and Judge Parker says in part:

For the guidance of all governmental agencies and all others interested (1) in the supply of labor, and (3) in the supply of transportation service by rail, water, pipe lines or otherwise, in so far as such service contributes to production of finished products, the accompanying designated Preference List No. 2 has been adopted by the Priorities Board, superseding Preference List No. 1 adopted April 6, 1918, and all amendments and supplements thereto.

Where it is imperative not only to maintain but to stimulate and increase production to satisfy abnormal demands created by war requirements, a high rating is necessary, even though the intrinsic importance of the product may be less than that of other products placed in a lower classification because of the fact that the supply of such other products equals the demand without the stimulus of its priority. Were it is necessary to speed the production of a particular product required at a particular time to carry into effect an important programme, a high priority is given although changing conditions may thereafter suggest and demand a reclassification. Certain plants produce commodities of great relative importance, but at the same time produce other commodities of less relative importance, and under such circumstances consideration and weight is given to the ratio of production between the more important and less important commodities. Instances occasionally arise where individual plants are given preference so long as they are rendering, and so long as it is in the public interest that they should render, a particular service, even though, taking the country as a whole, the supply of their product is ample to meet all demands.

The industries and plants grouped under Class 1 are only such as are of exceptional importance in connection with the prosecution of the war. Their requirements must be fully satisfied in preference to those of the three remaining classes.

Requirements of industries and plants grouped under Class 2, Class 3 and Class 4 shall have precedence over those not appearing on the preference list. As between these three classes, however, there shall be no complete or absolute preference. It is not intended that the requirements of Class 2 shall be fully satisfied before supplying any of the requirements of Class 3, or that those of Class 3 shall be fully satisfied before supplying any of those of Class 4. The classification does, however, indicate that the industries and plants grouped in Class 2 are relatively more important than those in Class 3, and that those in Class 3 are relatively more important than those in Class 4. It will often happen that after satisfying the requirements of Class 1 the remaining available supply will be less than the aggregate requirements of the other three classes, in which event such supply will be rationed to the industries and plants embraced within those classes. The Priorities Board will from time to time, after conference, and in cooperation with each of the several governmental agencies charged with the distribution thereof, determine particular principles, values and methods of application which may be followed in allocating fuel, power, transportation and labor respectively, to the end that proper reorganization and weight may as far as practicable in each case be given to the relative importance of Class 2, Class 3, and Class 4.

Each plant listed as such shall not later than the fifteenth of each month file with the secretary of the Priorities Board, Washington, D. C., a report on P. L. Form No 3 covering its activities during the preceding month. Any plant failing to file such report will be dropped from the preference list.

Priorities in the supply and distribution of raw materials, semi-finished products and finished products shall be governed by Circular No. 4, issued by the Priorities Division of the War Industries Board under date of July 1, 1918, and all amendments and supplements thereto or substitutes therefor.

This preference list shall be amended or revised from time to time by action of the Priorities Board to meet changing conditions. The Priorities Commissioner shall, under the direction of and with the approval of the Priorities Board certify additional classes of industries and also certify additional plants whose operations as a war measure entitle them to preference treatment.

List of Industries

Agricultural Implements.—See "Farm Implements."

Aircraft.—Plants engaged principally in manufacturing aircraft or aircraft supplies and equipment—1.

Ammunition.—Plants engaged principally in manufacturing same for the United States government and the Allies. —1.

Army and Navy.—Arsenals and navy yards.—1.

Army and Navy.—Cantonments and camps.—1.

Arms (small).—Plants engaged principally in manufacturing same for the United States government and the Allies. —1.

Bags.—Hemp, jute and cotton. plants engaged principally in manufacturing same.—4.

Blast furnaces.—Producing pig iron. —1.

Boots and Shoes.—Plants engaged exclusively in manufacturing same.—4.

Brass and Copper.—Plants engaged principally in rolling and drawing copper brass and other copper alloys in the form of sheets, rods, wire and tubes.—2.

Buildings.—See "Public Institutions and Buildings."

Chain.—Plants engaged principally in manufacturing iron and steel chain.—3.

Chemicals.—Plants engaged principally in manufacturing chemicals for the production of military and naval explosives, ammunition and aircraft and chemical warfare.—1.

Chemicals.—Plants, not otherwise classified and listed, engaged principally in manufacturing chemicals.—4.

Coke.—Plants engaged principally in producing metallurgical coke and by-products, including toluol.—1.

Coke.—Plants, not otherwise classified and listed, producing same.—2.

Copper and Brass.—See "Brass and Copper."

Cotton.—Plants engaged in the compression of cotton.—4.

Cotton Textiles.—See "Textiles."

Cranes.—Plants engaged principally in manufacturing locomotive or traveling cranes.—2.

Domestic Consumers.—Fuel and electric energy for residential consumption, including homes, apartment houses, residential flats, restaurants and hotels.—1.

Domestic Consumers.—Fuel and electric energy not otherwise specifically listed.—3.

Drugs.—Medicines and medical and surgical supplies. Plants engaged principally in manufacturing same.—4.

Electrical Equipment.—Plants engaged principally in manufacturing same.—3.

Explosives.—Plants engaged principally in manufacturing same.—3.

Explosives.—Plants engaged principally in manufacturing same for military and naval purposes for the United States government and the Allies.—1.

Explosives.—Plants not otherwise classified or listed, engaged principally in manufacturing same.—3.

Farm Implements.—Plants engaged principally in manufacturing agricultural implements and farm operating equipment.—4.

Feed.—Plants engaged principally in preparing or manufacturing feed or livestock and poultry.—

Ferro-Alloys.—Plants engaged principally in producing ferro-chrome, ferromanganese, ferro-molybdenum, ferrosilicon, ferro-tungsten, ferro-uranium, ferro-vanadium and ferro-zirconium.—2.

Fertilizers.—Plants engaged principally in producing same.—4.

Fire Brick.—Plants engaged principally in manufacturing same.—4.

Foods.—Plants engaged principally in producing, milling, refining, preserving, refrigerating, wholesaling or storing food for human consumption embraced within the following description: all cereals and cereals products, meats, including poultry, fish, vegetables, fruit, sugar, syrups, glucose, butter, eggs, cheese, milk and cream, lard, lard compounds, oleomargarine and other substitutes for butter or lard, vegetable oils, beans, salt, coffee, baking powder, soda and yeast; also ammonia for refrigeration.—1.

Foods.—Plants engaged principally in producing, milling, preparing, refining, preserving, refrigerating or storing food for human consumption not otherwise specifically listed (excepting herefrom plants producing confectionery, soft drinks and chewing gum).—3.

Food Containers. — Plants engaged principally in manufacturing same.—4.

Foundries.—(Iron.) Plants engaged principally in the manufacture of gray iron and malleable iron castings.

Fungicides. — See "Insecticides and Fungicides."

Gas.—See "Oil and Gas," also "Public Utilities."

Guns.—(Large.) Plants engaged principally in manufacturing same for the United States government and the Allies. —1.

Hospitals.—See "Public Institutions and Buildings."

Ice.—Plants engaged principally in manufacturing same.—3.

Insecticides and Fungicides.—Plants engaged principally in manufacturing same.—4.

Laundries.—4.

Machine Tools.—Plants engaged principally in manufacturing same.—2.

Medicines.—See "Drugs and Medicines."

Mines.—Coal.—1.

Mines.—Producing metals and ferro-alloy minerals.—2.

Mines.—Plants engaged principally in manufacturing mining tools or equipment.—3.

Navy.—See "Army and Navy."

Navy Department.—See "War and Navy Departments."

Newspapers and Periodicals.—Plants engaged principally in printing newspapers or periodicals which are entered at the post office as second-class mail matter.—4.

Oil and Gas.—Plants engaged principally in producing oil or natural gas for fuel or for mechanical purposes, including refining or manufacturing oil for fuel. or for mechanical purposes.—1.

Oil and Gas.—Pipe lines and pumping stations engaged in transporting oil or natural gas.—1.

Oil and Gas.—Plants engaged principally in manufacturing equipment or supplies for producing or transporting oil or natural gas, or for refining and manufacturing oil for fuel or for mechanical purposes.—3.

Paper and Pulp.—See "Pulp and Paper."

Periodicals. — See "Newspapers and Periodicals."

Public Institutions and Buildings.—(Maintenance and operation of.) Other than hospitals and sanitariums.—3.

Public Institutions and Buildings.—(Maintenance and operation of.) Used as hospitals or sanitariums.—1.

Public Utilities.—Gas plants producing toluol.—1.

Public Utilities.—Street railways, electric lighting and power companies, gas plants not otherwise classified, telephone and telegraph companies, water-supply companies. and like general utilities.—2.

Public Utilities.—Plants engaged principally in manufacturing equipment for railways or other public utilities.—2.

Pulp and Paper.—Plants engaged exclusively in manufacturing same.—4.

Railways —Operated by United States Railroad Administration.—1.

Railways.—Not operated by United States Railroad Administration (excluding those operated as plant facilities.)—2.

Railways. — (Street.) See "Public Utilities."

Rope.—See "Twine and Rope."

Rope Wire.—See "Wire Rope."

Sanitariums.—See "Public Institutions and Buildings."

Ships.—(Maintenance and operation of.) Excluding pleasure craft not common carriers.—1.

Ships.—Plants engaged principally in building ships, excluding (a) pleasure craft not common carriers, (b) ships not built for the United States government or the Allies nor under license from United States Shipping Board.—1.

Soap.—Plants engaged principally in manufacturing same.—4.

Steel-Making Furnaces.—Plants engaged solely in manufacturing ingots and steel castings by the open hearth, Bessemer, crucible or electric furnace process, including blooming mills, billet mills and slabbing mills for same.—1.

Steel-Plate Mills.—1.

Steel-Rail Mills.—Rolling rails fifty or more pounds per yard.—2.

Steel.—All plants operating steel rolling and drawing mills, exclusive of those taking higher classification.—3.

Surgical Supplies.—See "Drugs and Medicines."

Tanners.—Plants engaged principally in tanning leather.—4.

Tanning.—Plants engaged principally in manufacturing tanning extracts.—4.

Textiles.—Plants engaged principally in manufacturing cotton textiles, including spinning, weaving and finishing.—4.

Textiles.—Plants engaged principally in manufacturing woolen textiles, including spinners, top makers and weavers. —1.

Textiles.—Plants engaged principally in manufacturing cotton or woolen knit goods.—4.

Textiles.—Plants engaged principally in manufacturing textile machinery.—4.

Tin plates.—Plants engaged principally in manufacturing same.—3.

Tobacco.—Only for preserving, drying, curing, packing and storing same—not for manufacturing and marketing.—4.

Toluol.—See "Coke," also "Public Utilities."

Tools.—Plants engaged principally in manufacturing small or hand tools for working wood or metal.—7.

Twine.—(Binder and Rope.) Plants engaged principally in manufacturing same.—4.

War and Navy Departments.—Construction work conducted by either the War Department or the Navy Department of the United States in embarkation ports, harbors, fortified places, flood protection operations, docks, locks, channels, inland waterways and in the maintenance and repair of same.—2.

Wire Rope and Rope Wire.—Plants engaged principally in manufacturing same.—2.

Woolen Textiles.—See "Textiles."

(The term "principally" means 75 per cent. of the products mentioned.)

That there is considerable difference of opinion in the jewelry trade of New York as to the use of white gold as a setting for precious stones was indicated at a meeting of manufacturers. Arguments were offered in favor of the use of white gold both with and without precious stone settings, and a resolution submitted to the meeting which upheld the use of white gold when properly stamped. This resolution was referred to a committee.

Producers Want to Know Where Pig Iron Goes

A Very Close Watch is Being Kept to See That War Orders Have a Preference in the Matter of Distribution—Questions That Are Asked

NO. It's not an easy matter for us to keep going. We have a fairly large stock of material on hand, but it's going down rapidly. Our yards have not nearly as much pig iron and scrap as we generally carry, and it's not much of a job to see the day coming when we will have to curtail or quit entirely for a time." That was the opinion of a prominent stove manufacturer who was discussing the situation with this paper a few days ago. He had been interviewing a number of salesmen who were in touch with supplies, but he could get nothing definite that would help him.

"As a matter of fact the men who have charge of the distribution of pig iron in this district seem to have a lead on the government. They are already in control of the situation, and believe me the only chance you have to get a ton of pig iron is to have a contract that has a very direct bearing on the carrying on of the war. I was certain that the last time I went to the furnaces in Hamilton that I had put up a pretty good case for the stove maker, but I was simply asked if we could make a stove that could be shot at the German army in the place of shells. If so we could get pig iron. If not, we could not get any. We make a good many stoves, of different sizes and kinds, but we haven't anything that can be shot at the German army."

Questions That Are Asked

As a matter of fact the pig iron in this section of the country has been under control for some time, and in a very direct way, too. A questionnaire has been used, it being required that it shall be filled out in duplicate, one part going to the director of licenses of the War Trade Board at Ottawa, and the other to the company supplying the pig iron. The questions are as follows:

Please State

1.—The total tonnage of pig iron required based on your estimated monthly consumption from the first day of current month to December 31, 1918.

2.—What class of work this pig iron is to be used for and give the percentage of each class.

3.—What quantity of pig iron you now have in stock.

4.—What quantity of pig iron you have purchased.

5.—What quantity of cast iron scrap you now have in stock.

6.—What quantity of cast iron scrap you have purchased.

7.—The weight in pounds of your daily melt, not including scrap.

8.—The weight in pounds of your daily melt, including scrap.

9.—Approximately the number of melts each month.

10.—What castings you are producing each day directly connected with the government war programme and give weight.

11.—The percentage in weight of your melt now being used in producing castings directly connected with and necessary to the conduct of the war.

12.—If castings are being furnished by you applying on government orders direct, please furnish the order numbers; and if such castings apply on indirect government orders, give name and address of your principal.

The accuracy of the above report is certified to as being substantially correct to the best of my knowledge and belief.

THE VALUE OF THE TRAINING COMES OUT AFTER THE WAR WORK

Editor Canadian Machinery:

Sir:—My reply to "Mechanical Engineer" in the Sept. 26th issue is "not at the present time." He and the thousands of other head workers have every reason to feel injured at the present time under present wage scales, For the time being, the years of training and self-abnegation count for but little alongside of the mere ability to stand before a machine and keep its yawning maw filled with chunks of metal. The men who have planned, whose brains have made it possible for every cobbler and barber to turn out a lot of accurate work the first day in the shop, they have not received a just reward nor a fair proportion of the compensation which is rightfully their due.

It is a part of the epoch through which we are now going. The comforting thought is in the future, for of such conditions, "that too will pass." Other lines than mechanical are experiencing the same thing. Here in the U. S. with the railroads under Government control we find ignorant laborers fairly blustering with the high wages thrust upon them. Women clerks are taking the place of men clerks who have gone to the front, and are receiving upwards of a fifth more than the experienced men did before the war. Experienced stenographers in law offices who considered themselves well off at $15 per week leave and go into railroad work of the easiest kind at a fifty per cent. greater salary. Girls who couldn't make change in stores make good on such war work.

In machine shops the tale is the same. Foremen and superintendents are hard to get. And why shouldn't they be, when toolmakers and machinists are allowed to earn double the money. And directing a force requires a lot of head and training and patience. One of the ablest men in the heat treatment of steel in the east has been working for me for about a year doing light bench work; in applying for a position he said, "I want a job where all I have to do is my work—this planning and designing, this bucking the queernesses of human nature which I have done for a lifetime is the most wearing, most discouraging of all kinds of work." And so it is that some big industry loses a man that is worth $5,000 a year to it because it makes his road too hard for endurance, while he in turn is smoothing the path that hundreds of workers might earn big money and the coffers of the house be correspondingly swelled.

But when the war is over and the world settles down to peaceful pursuits again, then the engineer and executive will come into his own again. It is an impossibility to avoid some sort of a re-construction or transition period during which the manufacturing machine shops at least will disgorge their workers as formerly they drew them in. It takes years and months to change to any other line, just as it did to start munition work, and through all of that time the piece worker will be laid off. After indefinite lay offs and months of looking for work, the barber will naturally drift back to his chair and the cobbler to his bench.

Mechanical work appeals to most men and recent conditions have been the entering wedge long sought by thousands of them. These men will remain. They, reinforced by the men who return from abroad and skilled machinists on this side, will constitute the working force of the future. Their number and the slowing up of the re-construction period will automatically lower the wage scale, possibly very near to what it was four years ago.

The engineer and executive, however, will be more necessary than before Brains have always been the most excellent of hard time assets. Engineers can and will command more money than ever before, for the simple reason that under competition the best thrives and many of the makeshifts and misfits of to-day cannot continue. To meet the competition and keep men at work, old methods must be better and new devices must be brought out. To make these possible is the work of the engineer, work for which he will be equably paid.

"They copied all they could copy, but
they couldn't copy my mind
And I left them sweating and stealing
a year and a half behind."

—Donald A. Hampson, Middletown, N. Y.

WHAT OUR READERS THINK AND DO

Views and Opinions Regarding Industrial Developments, Factory Administration and Allied Topics Relating to Engineering Activity

REAMER AND ARBOR WHICH ARE GOOD PRODUCERS

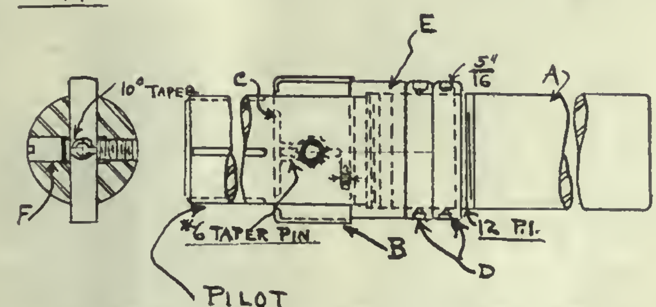
By F. Scriber

A REAMER made of flat stock and having two cutting edges which may be expanded to compensate for wearing, is illustrated in Fig. 1. This reamer was used in a turret lathe and the expanding feature makes it an economical tool in the utilization of high speed steel.

The boring bar itself A is made of machine steel, and is hardened and ground. The reamer B goes through a slot in the bar and is forced against the slot C, by means of the two adjusting nuts D, one of which is used for locking the other to prevent it from turning. Between the reamer and the collars a hardened and ground ring E is placed, this is a slip fit on the bar and is used to obtain a square surface so the reaming cutter will be forced squarely against the end of the slot. For holding the cutter central in the bar a tapered screw F is used.

When it is desired to adjust the cutter to compensate for wear on the edges this is done by removing the cutter from the bar and driving in the tapered pin which is indicated as number six, this expands the cutter, which is split almost through, or within ⅜ of the back edge as shown by the drawing, the cutter is then replaced in the bar and is reground to size.

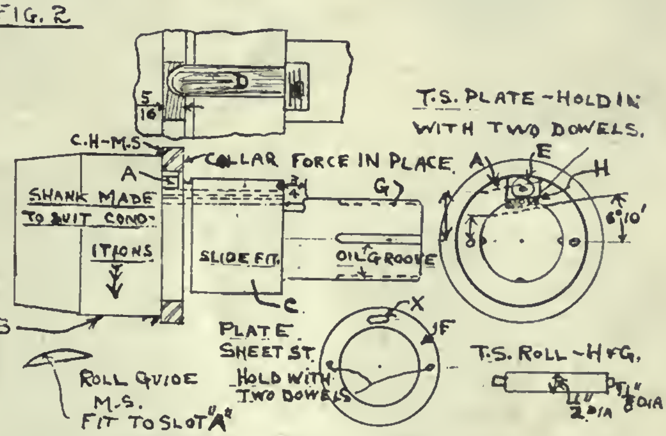
FIG. 1



EXPANDING REAMER OF THE FLAT CUTTER TYPE

In Fig. 2 an arbor of the roll grip type is shown, this arbor is held at B, in the spindle nose of the turret lathe, and is marked "shank to suit conditions." The work to be machined goes over the diameter C, and is pushed up against the collar which is shown in section. In this diameter C a slot is cut D, and in this slot a roll E is placed, this roll is also shown in the lower right hand corner of the illustration It will be noticed that both ends of this roll are turned down, the reason for this is that one of the ends turned down fits under the collar which is shown in section, while the other end fits in the slot X, of the plate F, shown below the arbor, this plate F slips over the end of the arbor G, and is held in place by the dowels noted.

FIG. 2



ROLL GRIP ARBOR FOR LIGHT WORK

In the lower left hand corner of the illustration a part indicated as roll guide is shown; this fits under the sectioned collar and helps to keep the roll in place. It will be noticed from the end view that a plate, H, is set in the slot at an angle, and the purpose of this will be understood by noting the operation of this arbor in gripping work, as, for instance, the work having a hole in it is slipped over the arbor at C, the arbor with the work in place revolves in the direction of the arrow, and when the cutting tools bite into the work, the roll E is forced up the tapered plate H, thereby causing the roll to grip between the hole of the work and this plate. This securely holds the work in position and drives the same under the cut.

This arbor has been found particularly adaptable for short operations where the cuts are not very heavy, as under heavy cuts it has been found that the roll will sometimes bite into the hole of the work, thus marring the same. Both of these tools used under proper conditions are found to be good economical producers.

THE CARE OF SCALES

By W. Schaphorst

Engineers and others in and about the plant often use scales in various ways without giving them much thought. It is generally assumed by the average engineer that if a scale "balances" before the load is put on, the weight registered will be "accurate," but such is not always the case. Much depends upon the care given the scale between weighings.

It might, therefore, be a good plan to say a few words about scales in these columns for a change.

In Figure 1 is shown a so-called "knife-edge." On top of the knife-edge is the bearing. Both the bearing and knife-edge should be made of the same material, of equal hardness. The harder and stronger the material used the better, in most cases.

However, it is evident that we must have more than mere "line contact" when there is any sort of load on the scales. The knife-edge on a jeweler's scale may be so sharp that one could shave with it, but on the high capacity scales the knife-edge is really nothing more than a blunt edge, and in the largest scales is actually a flat surface without semblance of a point or "edge."

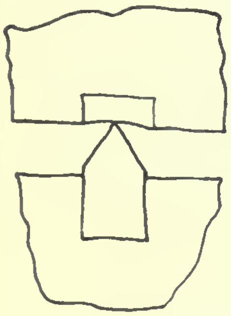


FIG. 1

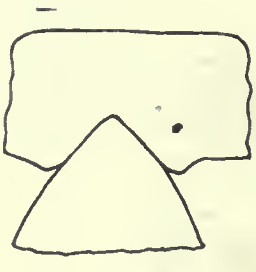

FIG. 2

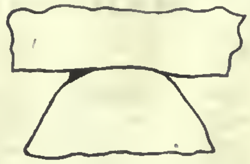

FIG. 3

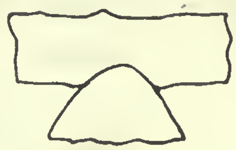

FIG. 4

Yet, they are "called" knife-edges, although the proper word would be "pivots."

Figure 2 is an imagined enlargement of what occurs where the knife-edge is harder than the bearing. It is evident that the principal deformation will take place in the softer metal.

Figure 3 shows a case where the knife-edge is soft and the bearing is hard. The knife-edge, of course, will be "blunted down" pretty much as shown.

Figure 4 shows a case where both metals are of the same hardness. That is the "ideal" case, although it would be much nicer if we could get away from surface contact altogether. Theoretically, the ideal case is a "line" pure and simple. If the line could be attained in actual practice things would be simplified very much for the designers of scales.

To keep a pair of scales in good condition it is, therefore, important that they be never overloaded. Overloading may deform the knife-edges of bearings permanently. Never allow a weight to drop heavily upon the scale platform, for blows are liable to deform the edges, too. And never allow a heavy weight to remain long upon the platform. Give the knife-edges an opportunity to return to their normal shape as soon as possible after the weighing. A long-sustained heavy load will cause the knife-edges to "flow" and remain deformed permanently.

To date, the best metal for knife-edges for use on high capacity scales is the high-speed steel that is used so much in machine tool work. A new metal called stellite, however, has lately been put on the market as superior to high-speed steel. It is exceedingly hard and will scratch the hardest hardened steel. There is no iron in stellite at all except as an impurity. Stellite is very likely the coming metal for knife-edges. It has another advantage over steel in that it does not corrode.

BENDING CAST IRON PIPES

By M. E.

A successful bending of large straight cast iron pipes was recently effected in making the line of cast iron pipe which it had been decided to lay to convey water from the Guayabo River to the town of Present, Cuba. By mistake no sleeves or curves had been ordered. The canyon through which the pipe passes for a distance of about two miles from the dam is crooked, making impossible such easy curves as would be made in the pipe joints. As it might have taken several months to secure additional special pipes, the local engineer decided to bend some of the straight cast iron pipes. The Cuban workers had frequently bent steel or wrought iron pipes at their sugar mills, and they followed the same course of procedure with the cast pipes, with entire success, as they did not break or spoil a single pipe. The pipes were bent to various radii, the shortest being 50 feet. A cradle of old rails was first constructed with the desired amount of curvature, and a fire of hardwood was built under and around the pipes. Six or eight pipes were bent at a time. In one and a half or two hours after starting the fires, the pipes were hot enough to bend and settle under their own weight on to the cradle prepared for them. The pipes were 10 in. in diameter with 9-16 in. thickness of shell. their weight being about 760 lb per 12 feet length.

HAMMER HANDLES

By M. M.

In a large number of places it is customary to supply both hammer and file handles to the men on demand, this often leading to considerable waste, particularly when the cheapest kind of handles, irrespective of quality are provided. So far as files are concerned they should be issued with the handles fitted, charging each man with the issue and crediting him with the return of the old file and handle to the stores. The file probably goes to the scrap head, but the handle can be used many times, and if not returned to the stores the user should be called upon to pay for it. On regard to hammer handles there should be a man attached to the stores who can handle hammers properly, and instead of giving out handles to all who apply for them, the hammer, with the broken handle, should be given to the proper man to be fitted with a new handle at once. Properly put on, a hammer head should not leave the handle, and as the user gets used to the "feel" of the hammer he takes care of it, a thing he does not do when the hammer is a bad fit in the handle. Either well-seasoned hickory or cleft oak handles should be used, and the size should be suited to that of the hammer to which it is attached. Handles are only minor items, but they count for a great deal in doing work.

PURE SHEET-NICKEL

Pure nickel should not be confounded with the inferior metals usually sold as nickel, which consist mostly of steel, brass or German silver with a thin plating of nickel. Nickel is essentially an American product. For many years it has been a general practice to have the ore which has been mined in this country and Canada reduced to its various forms by European manufacturers. Previous to the war most of the material imported into this country as foreign stock was the American metal worked into the form of sheet, strip, and finished articles of manufacture by foreign concerns.

Pure nickel does not rust nor oxidize, and consequently every danger of poisoning, generally caused by verdigris, is eliminated. Neither will the metal tarnish like silver or some of the alloys, such as German silver, and, even though the surface be injured there is no danger of corrosion resulting as in a plated article.

While not so good a heat conductor as aluminum, nickel utensils are made of a thinner material, which more than overcomes the difference. Pure nickel has a melting-point of abut 2,600° F., whereas aluminum has only one of about 1,200°. There is not the same possibility of softening under constant use. The metal is also much more resistant to the action of the acids commonly found in food products. The silver-like appearance of pure nickel does not change in use.

In the chemical field there are many uses for this metal. The surface of pure nickel is not attacked by acids nor alkalies, in the dilute form usually encountered in ordinary service. In fact, it is practically immune to the attacks of all alkalies, regardless of their strength, and is largely resistant to the action of most acids. Nickel has a high tensile strength, and in the sheet form. being homogeneous throughout, is ductile and easily formed by spinning or stamping. No special equipment is necessary for manufacturing articles from these sheets, the same tools and metals being employed as with German silver and hard alloys.—The Journ-Franklin Inst.

DEVELOPMENTS IN SHOP EQUIPMENT

Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.

CONTINUOUS PHOTO-PRINTING MACHINE

The illustrations show a continuous photo-printing machine, used in conjunction with an automatic washing and drying machine, both of which were designed and constructed by the C. F. Pease Company, of 213-231 Institute Place, Chicago, Illinois, U.S.A., and are sold under the trade name "Peerless." With these machines a single operator can print, wash and dry 100 linear yards of blue prints per hour, during which time the apparatus consumes 7 units of electrical energy, 60 gallons of water, and 50 cubic feet of gas. It is, of course, quite possible to use the machine for part of the time only if such a large output is not required. The operator's time can then be occupied in other ways, and the working costs correspondingly reduced. Prints can also be made on separate sheets of sensitized paper, instead of in continuous rolls, if desired. Fig. 1 is a front view of the machine, and Fig. 2 is a side view, showing the course of the paper through the apparatus. The table from which the tracings are fed into the machine will be seen in Fig. 1, and beneath it are two horizontal spindles which carry rolls of sensitized paper of different widths. The tracings and paper are carried upwards over a cylindrical segment of thick plate-glass by means of an endless canvas belt, best seen in Fig. 2. Springs are provided to keep the belt tight, so as to ensure good contact, and side travel

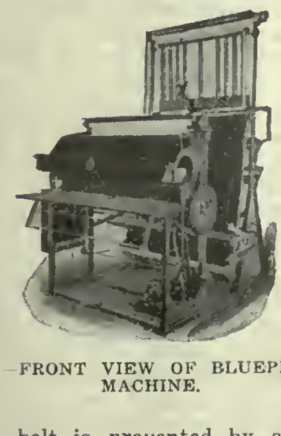

FIG. 1—FRONT VIEW OF BLUEPRINTING MACHINE.

of the belt is prevented by a special device. The belt is driven by a small electric motor, the speed of which is controlled by a rheostat placed on the right-hand side of the machine; both motor and rheostat are clearly shown in Fig 1. By means of the rheostat, the speed of the paper can be varied from 4 in. per minute, which allows sufficient exposure for the slowest negatives and black-line prints, up to 6 ft. per minute.

The exposed paper can be examined immediately it has passed the glass segment, so that the speed can be adjusted to give the right exposure before any prints have been spoilt. In front of the glass is a bank of five arc-lamps, of the enclosed type, fitted with aluminum reflectors. Each lamp is separately wired and controlled by switches, which are enclosed in a metal box on the left-hand side of the machine, as shown in Fig. 2. The number of lamps employed can thus be varied according to the width of paper being used. The motor-switches are also enclosed in the same box, and

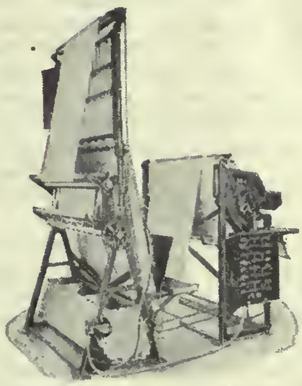

FIG. 2—SIDE VIEW OF MACHINE.

all the wiring is encased in steel tubing. A small electric fan of the pedestal type is mounted on top of the switch box. This fan, which can be distinguished in Fig. 2, drives a current of air in a transverse direction through the machine, in order to carry away the heat from the lamps.

Fig. 3 shows how easily accessible the lamps are for trimming and cleaning, and also illustrates how they may be turned back to facilitate these operations.

After printing, the tracings are delivered into an enamelled iron trough in front of the machine, so that the operator can remove them without changing his position. This trough, which can be seen in Fig. 1, also serves to catch the exposed sensitive paper if the printing machine is used independently of the washing and drying equipment, as is often the case. Usually,

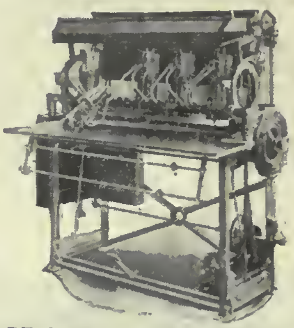

FIG. 3—REAR VIEW OF MACHINE SHOWING ACCESSIBILITY OF LAMPS.

however, the exposed paper passes over a roller at the top of the printing machine, and thence to the washing and drying machine, as shown in Fig. 2. This part of the apparatus is driven, by means of chains and sprocket wheels, from the motor of the printing machine, and in it the paper is first washed by a spray of pure water, and afterwards treated by a weak solution of potassium bichromate. This solution is contained in a galvanized tank placed in the base of the machine, and clearly visible in Fig. 2.

From this tank the solution is circulated by a small rotary pump, driven by an electric motor, having a vertical shaft, and delivered on to the paper through a flexible pipe; an inspection of Fig. 2 will make the whole arrangement clear. After a further washing with pure water, the paper passes upwards in front of the drying device, over a roller at the top, and down at the back of the machine. Here it passes through a system of rollers which carry a series of elastic bands, running in opposite directions, and forming part of a device for rolling up the finished prints. These are wound up on a shaft, but the end of the paper, as it descends from the roller at the top of the machine, is formed into a loose roll, and this roll of finished prints entirely free from wrinkles and distortion, being placed upon the bands, continues to roll itself up automatically until the operator wishes to cut it off and start a new roll.

ALL-STEEL WORK STAND

The field of the work stand has become so varied and its use so general as to render a definition of its purposes, or argument in favor of its employment, superfluous.

The work stands illustrated are made of steel throughout, their unique construction affording ample strength with minimum weight, stability and durability, without clumsiness.

The two legs at either end are formed by a single steel angle, whose continuation across the top adds both rigidity to the construction and a finish to the rack's appearance.

The trays are of such material and design as to render them remarkably stiff and substantial. The strengthening influence of the 2-in. flange along sides and back is supplemented by a formed hem, which also supplies a smooth finish to edge of tray. Forward edge is turned down to afford most convenient access to, and facilitate cleaning of, trays. At the corners are welded gussets by which trays are bolted to uprights and given additional support. Stand has no sharp corners or ragged edges by which accidental injury might be sustained.

Stand may be had with two or three trays and with or without drawer. Height to top tray, 32 inches. Size of trays, 16 inches by 26 inches.

ALL STEEL BENCH STAND

A hem of triple thickness around its upper edge and the welding of all joints combine to produce a drawer of remarkable strength and rigidity.

The slide ways are welded to under side of top tray, and give to drawer a smooth movement free from binding or cramping tendency.

Drawer handle is of generous size with a shape of special design, affording a very comfortable handhold.

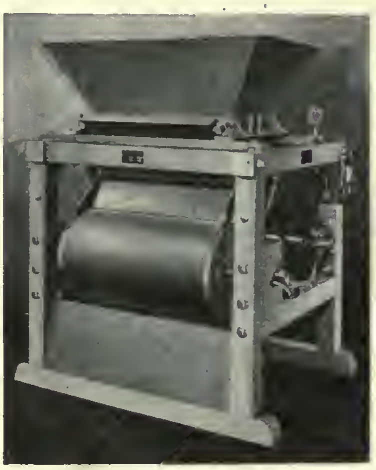
A cylinder lock of good grade, with two individual keys, is provided. Master keying if desired may be had at cost. The possession of master key by foreman will prevent the stowing of contraband in drawers.

The stands are shipped knocked down and may be most easily and quickly assembled as follows: Insert bolts in one side angle and lay it flat on floor or box. Place trays on edge in proper positions and add nuts. Apply other side angle to upper edges of trays and insert bolts. Then stand tray upright and firmly tighten bolts.

These stands are manufactured by the New Britain Machine Co., New Britain, Con.

MAGNETIC SEPARATORS

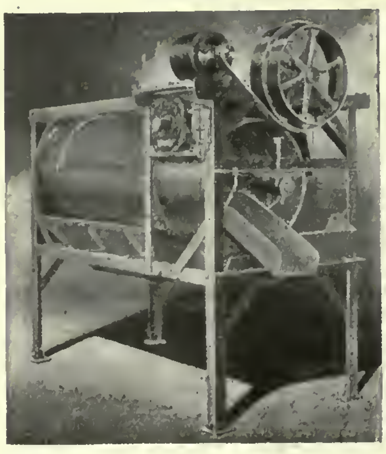
THE Magnetic Mfg. Co., Milwaukee, Wis., are manufacturing a variety of magnetic separators for use in the foundry. One of the great advantages of using a machine of this nature



MAGNETIC SEPARATOR.

is that the sand is left in a clean and uniform condition and may be used in various ways in the foundry. The machine is very simple to operate and does not require skilled labor to get the best results. It will not clog and will take care of any material that would be handled with a shovel, such as stray brick, gaggers and other coarse material usually found in foundry refuse. All parts are accessible for inspection without dismantling.

The material is shoveled into the machine at the upper end of a revolving screen. Sand and fine material passes through the screen into a hopper and may be caught into a wheelbarrow. The other material passes on through the



ANOTHER TYPE OF SEPARATOR.

cylinder and comes in contact with magnetized blades where the iron being attached to the blades is carried up to top of cylinder and then discharged into a chute.

One of the commendable features in this separator is its simplicity. There are no friction wheels or level gears to wear out or give trouble. There are only four bearings on the machine. The two main bearings supporting the revolving cylinder are properly proportioned and are made dustproof. The only other bearings are the two small countershaft bearings located on the top.

NON-CRUCIBLE MELTING FURNACE

The Hausfeld Company of Harrison, Ohio, is the manufacturer of the furnace herewith illustrated, which was designed particularly for the melting of brass and kindred materials. It is of the open-flame, non-crucible, tilting type and has a capacity of 400 pounds.

A "complete unit" consists of the furnace proper—lined ready for service—equipped with a Maxon Premix Burner, a one-half-horse-power motor (D. C. or A. C.), a patented fuel oil-feeder with burner and a pouring ladle, all as shown in illustration above. No equipment other than piping to the gas and the fuel oil reservoir is necessary. The furnace can be had without the fuel oil feeder and burner if desired, but for emergency purposes in event of failure of the gas supply the complete unit is almost essential.

One of the advantageous features of the complete unit is the facility and speed with which a change from gas to oil fuel can be made. As stated in a descriptive booklet of the furnace, a copy of which can be had upon request:

"The speed with which a change from gas to oil fuel, or vice versa, can be made may be best explained by the statement that a heat started and half finished by gas was finished by oil as the fuel in practically the same time had the change not been made." The change is accomplished by loosening two bolts, sliding the oil feeder housing forward, thereby placing the feeder into gear with the motor, tightening the bolts, removing the plug in the top of the elbow attached to the drum, and inserting the oil burner.

Although of compact form, occupying the minimum amount of space, the oil feeder develops a lift of over 18 feet, and has a delivery pressure of over 60 pounds. It is equipped with a relief valve capable of regulation, the outlet of which is piped to the oil reservoir, permitting the return of any excess quantity of oil.

The patented oil burner provides for heating the oil prior to its injection into the furnace. The location of the needle point seat being at the extreme end of the outlet causes a spray of wide range. To increase this range and break large particles of oil, a small division bar is located directly in front of the burner outlet. With this arrangement every drop of oil is satisfactorily utilized, and the oil being preheated and so finely atomized results in quick ignition.

As the flame, whether from gas or oil fuel, covers the entire inner surface of the furnace, a uniformly distributed heat is obtained and the metal is thereby melted largely by reflection of the heat from the walls, similarly to the effect obtained by melting in crucibles.

The plain shape of the drum facilitates relining. The bricks furnished have locking joints to prevent the seepage of metal. The manufacturers claim that both the brick and cement employed have excellent refractory qualities and withstand by far a greater number of heats than any other with which they have experimented.

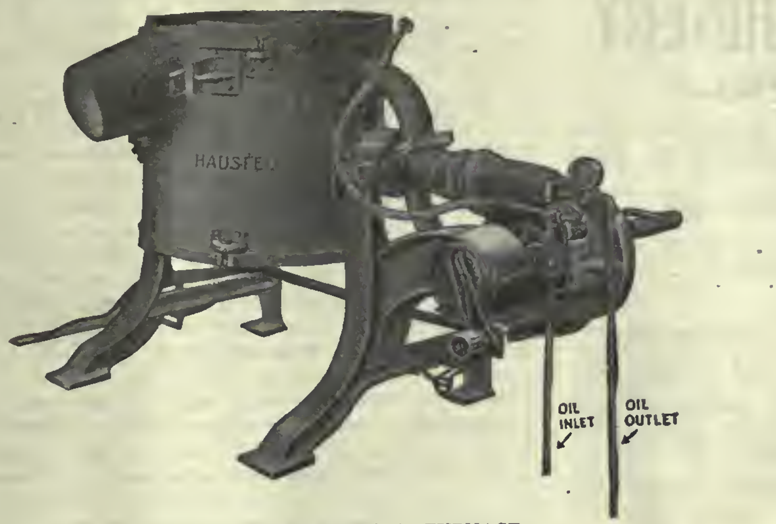
Depending upon the character of the metal to be melted, from 9 to 12 heats can be obtained every 9 hours.

With the furnace drum in a vertical position, the furnace can be charged with gates and other scrap, while the blast is on, the metal being thrown on top of the drum where it preheats and then shoved into the charging hole, by means of a bar, as fast as desired.

The pouring ladle is located directly over the pouring hole where it remains during the melting of the entire heat. By this arrangement the ladle is heated to a temperature almost equal to that within the furnace and a separate preheating furnace is dispensed with. It also materially aids in retaining the heat within the furnace.

The furnace is tilted by means of a handle of a length sufficient to provide ample leverage for easy manipulation. The locking arrangement is spring actuated and tends to keep a bar on the frame in constant engagement with the teeth of a sector attached to the drum, securely holding the drum in any position desired. The release of the lock is effected by foot pressure on a treadle at the base, permitting the use of both hands for tilting or rocking the drum. For convenience, a double treadle is provided, one extending to the front and the other to the rear of the operating side, so that when tilting the treadle most convenient is used. Upon release of the foot pressure the drum is instantly locked.

The Hausfeld Company guarantee efficient and satisfactory results if the furnace is installed and operated in compliance with instructions furnished.



NON-CRUCIBLE MELTING FURNACE.

CANADA'S AFTER THE WAR TRADE

Call For Organization of Business Interests

In the report on Canada's trade in 1917, the Deputy Minister of Trade and Finance emphasises the urgent need for preparing commercial organizations for after-war trade.

His statements, although directed towards the business men of Canada, are applicable to any country that intends to occupy a leading position as an exporting country after the war. For this reason, the views enumerated by the Deputy Minister are quoted below. In his report he states:—

Germany's Economic Position

When hostilities cease and peace is declared, if the cartel systems of Germany be co-ordinated and in reality become not only nationalized, but also become State monopolies, as has been announced is the intention, private firms and individuals will find the most formidable possible competition in every market in the world. Such monopolies, backed up by the concentrated strength of all the banks of the German Empire, will be able to purchase in large quantities under the most favorable conditions, and to sell at prices and upon terms to render competition extremely difficult, if not impossible. Thus will Germany wage economic war.

When such commercial war begins, Germany will have its shipping, now locked up in its harbours, its factories unscathed by the ravages of war, and hundreds of thousands of labourers returning to commercial pursuits, ready to work for the merest living wage, but Germany must look abroad for many raw materials vitally necessary to her commercial existence, for many of which she is dependent almost wholly upon her present enemies. To a lesser, though important, extent she is dependent upon the British Empire, and in many important respects upon Canada also. In fact, so far as Canada is concerned, apart from her grain exports, the nickel and asbestos production of the Dominion are greater than all the rest of the world put together.

In considering, however, the statement frequently made that the German factories will be ready at the close of the war to offer keen competition to the world, it may be well to draw attention to a more recent statement which, if true, considerably alters the general opinion as to Germany's position. That statement is to the effect that many factories in Germany which have not been engaged in war work have been stripped bare of their machinery, which has been transferred elsewhere. Under these circumstances, a factory which has been closed down cannot be presumed to be able to resume work immediately on the restoration of peace. Such factories must be rehabilitated with new machinery, the manufacture of which will require considerable raw material.

Organization Imperative

Is it not, therefore, urgent that the various industries in Canada, especially those producing food and raw or semi-raw materials, should organize upon such a basis as will conserve these products for Canada and the Empire? If we let them go loosely to the first or highest bidder—and Germany with exhausted stocks of raw materials will be in the forefront as a buyer—the demand will naturally lead to extravagant prices, which, of course, will re-act upon ourselves and increase the cost of production and manufacture in Canada.

Collection of Statistics

While no one can forecast what the conditions of business may be when the war is over, the time has arrived to prepare for every possible eventuality by widespread organization of every industry in Canada. Each industry should prepare complete and accurate statistics of the most exhaustive nature with respect to itself, so that if necessary such information will be available not only during the progress of the war, but also when the Government is called upon to study tariff problems at home and tariff arrangements abroad.

Co-operation in Export Trade

Such organizations are not inferred to be in the nature of trusts to dominate prices or to restrain trade in Canada, but for the purposes of assisting and advising the Government with all possible information in respect of such industry, and also engaging in export trade. Co-operation in export trade will be necessary to meet similar foreign export syndicates. Such combinations develop men of initiative and constructive genius.

Keep Up That Wall of Steel

THE Germans may talk peace—they may get Austria or Turkey to hoist the white flag—but the shell factory gives the answer of the Allied nations.

Did you hear of any shell contracts being cancelled on Monday morning on account of the German peace talk of Sunday?

Did you hear of the call being any less for 18-pounders, the 75-m.m., the 155-m.m., the 9.2 or the six-inch?

Not a bit of it. The forging and the machining were going on just the same as though there had been no peace talk, and the shipments were going on with the same unfailing regularity.

As a matter of real fact, the Kaiser's peace kite didn't get the eyes of the world long enough to make the munitions workers miss a single operation.

And there's no let up in the Allied programme that calls for more than capacity production of the steel plants of the continent. Every day sees the figures shoved up a few more hundred or thousand tons; every day sees another non-essential line told to suspend operations; every day sees a customer told that there's no steel or iron for him because he's making a line that can wait; every day sees the whole commercial and mechanical fabric of the continent keyed up tighter and harder for ultra-maximum production.

The men who control the steel output of this continent know the enormous tonnage that is being turned out—they know it is a case of steel or men—the more steel the lower the casualties, and they are seeing to it that the wall of steel that precedes the march of the Allies eastward is tremendously efficient and perpetually maintained.

The whole business of the nation has been thrown out of kilter, and it is going to stay out of kilter. The war needs occupy the centre of the arena, and there's no disposition to crowd them to one side.

The Kaiser and his war lords started this war; they lived it years ago; they planned for it and they plotted and schemed for it. But the Kaiser and his war lords are not going to finish this war. That part of the performance is going to be attended to by the Allied nations of a free world.

The Allies are not fighting for the sake of fighting. The lives of their men are dear and precious to them. They will not fight five minutes longer than is necessary, neither are they disposed to cease five minutes before they have accomplished the task to which they have set their hand.

The latest indications from the front should be a challenge to the munitions workers of this continent.

If you are making shells, make more of them and make them better.

You can hasten the end of the war by keeping up that wall of steel that goes on ahead of the Allies.

Don't bother about the Kaiser's peace proposals. The diplomats of the Allied powers are acting in concert and in complete accord, and they are not going to betray the trust that is theirs.

Peace will come, and it may come quickly. Against that is the chance that it may not. Base your efforts on the latter. Better to have a pile of shells left over than that there shall be a break in the wall of steel that the munitions workers are building on that Western front.

Better Play It Safe This Time

MECHANICS are these days receiving exceptional wages. Some of them, most we hope, are salting away neat little sums for the rainy season. Among the thrifty, Victory Bonds are regarded as one of the premier investments, and the new issue will undoubtedly be very largely taken by this class. But occasionally one hears of cases in which men have not been careful—when, in fact, they have been reckless as regards their own futures and those depending upon them. An actual instance that stands out is that of the mechanic who was a bear to work and who was making something like $3,000 a year—probably more than the superintendent of his shop was receiving. He was, in fact, a good workman. This man purchased a car—not a flivver—a car. One night while out driving with his wife, he met with an accident. The car turned turtle; he was killed and his wife was seriously injured. The after records revealed that the man owned the car—an $1,800 machine. It was paid for. In the home there was a piano on which two payments had been made; there was a life insurance policy for $500 and a chattel mortgage of $400. The machine had been smashed—it was worthless. This was the record of a man who had been making exceptional money—and this is the record of what he did with it—practically nothing to place on the credit side against disaster. There are many men who will say it is nobody's business what they do with their money. Probably not; but to a good many others the good old moral will appeal: Buy Victory Bonds and give the clouds a silver lining.

Visitor—And what caused this sad case?
Helper—That sir is a journalist who went to write up the Russian situation."
—F. A. G. Racey in "Montreal Star."

Protection Needed For the Public

THERE are controllers for fuel and for food. There are officials to see that people don't eat too much, and there are others to see that they don't burn too much coal.

The country is sadly in need just now of a controller or some such official whose special duty it will be to see that the general public don't get soaked when they come to spend their money.

The people who need protection right now are the people who spend their money and get in return an article that is a fraud and a scandal. People need protection against shoes that are sold as leather, and which in reality have only the merest touch of leather to cover up a lot of substitute. They won't stand up against wear. And yet they are sold in the open market and at a good price.

People need protection in the purchase of clothes. The average purchaser is not an expert in this business. He cannot readily detect shoddy. And yet he puts up his good money for the clothing of himself and his family, only to find that he has paid a good price for something that is scandalously distant from what he was led to believe.

"Get the money" seems to be the big word in too many business concerns now. The idea of "service" is being crowded so near to the back door that it's not going to take a great deal of coaxing for it to depart entirely from the premises.

"Get the money." The people have it now. "Get the money." Never mind what follows. "Get the money." There's a new bunch of suckers coming on the market every Monday morning. "Get the money." Don't worry about the man who is spending it—he's supposed to have his eyes open.

There are men and firms who are doing business in an honorable way. Against such the public needs no protection. But in this age of money-grabbing shysters there certainly is need of ample protection against the gang of exploiters that are foisting their shoddy rubbish on the market.

AND now the report comes out that the prune crop is going to be a failure. Maybe so, but there's never a failure of the prune crop that's swished about in the boarding houses.

* * *

U.S. has placed soft drinks, pianos, corsets and coffins on the non-essential list. Well, as a matter of fact, there's a lot of folks around who have got along without any of this stuff.

* * *

SULPHUR is getting scarce. So scarce, in fact, that the chances seem to be much against the youngsters getting their 1919 spring tonic in the form of sulphur and molasses. It's a great age to be livin' in.

* * *

THE Secretary of State for Canada has stopped the publication of the Robotchyj Narod. Of course he put it down in writing so it didn't hurt him much.

* * *

THE Probs. in a Toronto paper the other day read: "Thursday—Mostly fair, with a few showers, stationary or slightly rising temperature." So it could either be fair or showery, same or higher temperature. The weather man was taking small chance of spoiling his rep. that day.

* * *

KEMPSMITH Komments, the house organ of the Kempsmith Mfg. Co., Milwaukee, Wis., has a number of names on its honor roll. Here are a few of them: John Samolinski, Joe Koniecki, Max Wojczak, Vincent and Arthur Wielant, Joe Vuchmanavich, Alfred Weisbecker. And they all line up under the name of "Yanks." The German menace is just as acute to a Vuchmanavich as it is to the most Simon pure New Englander that the country can boast.

A Vision of Former Dinners

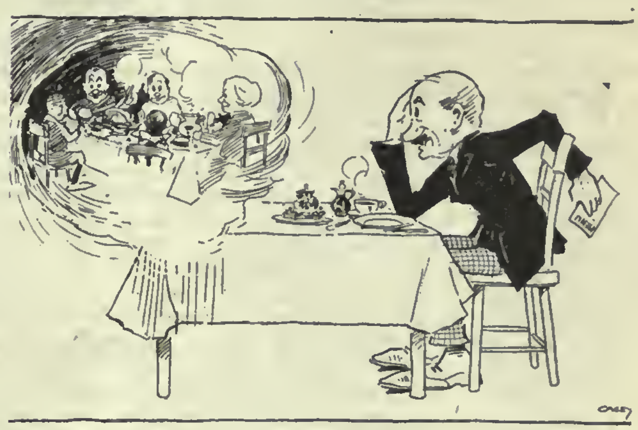
WHEN we go out to eat these days we have to sit and wonder, if food controller's hit the list with lightnin' and with thunder, or if he's put some more laws on to choke us from our hash, or if he's took from us our oats, our hay and our bran mash.

And when I see the sugar lump I sit and heave a sigh, for you could stick the bloomin' thing right edgeways in your eye.

And likewise bread is trimmed up thin, and butter, oh by heck, there aint enough doled out to grease the hair upon your neck.

Oh, I like to sit in times like these, and back up twenty years, to them there days what come along and boot away my tears—to the good old days of harvest homes when tables used to groan, and when we ate full to the neck for a quarter of a bone.

We used to take the punkins then, the corn stalks and the beets, and decorate the church throughout, the pulpit and the seats.



And put the big potatoes there, likewise the apples red, and cabbages as big and hard as was the deacon's head—and twine the oak and maple leaves, and spin the golden rod, and have a sample of most things what sprung from out the sod.

And then we had the harvest home—come back once more that night—when stuff to eat was piled up high and tucked in good and tight.

We ate some turkey and some ham, some chicken and some pie, we had a heap of sandwiches heaped up both thick and high. We ate, we did, until we groaned, and then we ate some more, and every course that came along we hollered out "encore!"

And after all that there was done they'd clear away the wreck, and all the preachers round about would climb upon the deck, and tear off jokes ten years of age and try to speechify on top of fourteen kinds of meat and sixteen kinds of pie.

There weren't no food controller then a-hangin' round the place, to see how much you gathered up and shoved into your face.

I'd like to be a kid again just for one harvest home, with sawhorse tables loaded up until they'd creak and groan—with punkin pies and chicken too, with home cured country ham, and best of all, by jing, there weren't no food controllin' man.—ARK.

Tin is coming down to where it will soon be on speaking terms with the rest of us. Not long ago it had reached the dizzy height where a pound was worth well nigh $1.50. Now it can't quite get its chin up to the dollar mark even with one toe on the ground. About the time tin hit the $1.50 mark there should have been a couple of lynchings.

* * *

THE war and its ravages has made a great demand for artificial limbs. And now, because metal is so scarce, they're talking of putting wooden legs on sewing machines.

MARKET DEVELOPMENTS

Peace Talk Has Made No Difference Here

There is Still a Very Keen Demand For All Sorts of Equipment, Especially in Connection With 155-mm. Shells—Ship Programme is a Big Business Item in Canada at Present

PEACE talk has not made much impression on the programme for the speeding up of the production of munitions. In fact the actual operations have not been interfered with at all. There is just the same demand to-day as there was before the week-end peace talk, and there is the same uncertainty regarding delivery dates, due to the tremendous pressure under which the makers of munitions equipment are working.

It is a poor week when some person has not a new guess as to the amount of business that will be handled in the future by the war contract shops of the Dominion. One report has it that U. S. manufacturers feel that they are in a position to handle the shell programme, and they desire no more business to come to Canada. As a matter of fact munitions business is not coming to Canada because the U. S. firms want to send it here, but because the munitions shops in Canada are right now keyed up to a wonderful degree of efficiency in producing shells, and the government that wants good shells at once can get them from the Canadian contractors. The largest orders for equipment now have to do with the production of the 155-m.m. shell, which is an American order.

The curtailment of iron and steel to those concerns making a product "that can wait" continues. And as it continues the industries are displaying a faculty for keeping afloat that is indicative of Canadian enterprise. Makers of sewing machines are having a hard time securing the supplies of pig iron they need to make up their proper mixture with scrap, so they will shortly turn out machines with wooden legs, saving quite a bit of iron in this way and sacrificing nothing in the way of strength and rigidity in construction.

The big demand continues to be for steel plate. The making, shipping, punching and putting together of the steel plates for the vessels now under construction in Canada has developed into a business that few people apart from the trade fully realize. For instance here is what it means to the transportation companies having the transcontinental haul: For the material that went into the construction of a 4,200-ton vessel in Vancouver (the largest part of which would be plate) the company paid out between $75,000 and $80,000 in freight charges.

The scrap metal trade is dull. Dealers are not buying heavily. In fact in some cases they are accepting shipments simply in order to protect their credit and keep in the market. Large volumes of scrap are disposed of direct from seller to consumer. Dealers fear that industries that cannot get into the iron market, may cease buying scrap because they cannot get pig enough to complete the mixture. At any rate the trade is well nigh stagnant as far as big deals are concerned.

PEACE TALK HAS HAD LITTLE EFFECT IN THE MONTREAL MARKET

Special to CANADIAN MACHINERY

MONTREAL, Oct. 19.—Despite the reported willingness of the German Government to meet the Allies for the consideration of peace the activities for the prosecution of the war are proceeding unabated. The feeling, however, is undoubtedly manifest that the beginning of the end is in sight, and while it is not anticipated that present activities will immediately cease, it is not unlikely that the near future may see some easing up in the operations of some enterprises that are now working to capacity.

Steel For Work Exclusive

On a par with the manufacture of munitions is the imperative need of boats for transportation to offset the continual destruction by the submarine. During the past few months the importance of shipbuilding has been impressed vividly on the minds of the Allied Governments and every facility has been given to the increased production of plates for this industry. The consequence has been that further restrictions have been placed on the distribution of plates, and in some instances large locomotive firms have experienced increased difficulty in getting their accustomed allotment for boiler construction. Another instance that demonstrates the priority shown to shipbuilding is the increased difficulty that makers of large pipe have in obtaining supplies for their mills, as the mills working on this material is largely utilized in turning out ship plates.

Some theorizing is taking place as to the possible developments in the steel trade should active warfare terminate in the near future. Some speculation is made regarding the non-essential demand for steel at the present time and which the mills are unable to take care of. While some think that a great part of the current production could be diverted to domestic requirements, it is a question whether this demand will be as apparent as it is now. The mills that are now working on rounds for shell billets could undoubtedly meet every demand for this class of steel, but in the matter of plates and shapes the solution is more difficult. The present program for ship construction will not likely be reduced and transportation needs will almost equal that of the war period, so little relief can be expected in this direction. The period immediately following any serious peace considerations will probably result in a slightly easier situation as to structural material, but the imperative need for this class of steel will return when the reconstruction period is well under way. The news of the past few days has given an uncertain air to the general situation and few will commit themselves as to possible developments.

No Relief In Tool Situation

Machine tool activity at the present time is virtually confined to the production of equipment for the manufacture of war supplies. The question of prompt delivery is seldom mentioned in negotiations, as the heavy demand for machinery makes it impossible to obtain definite assurance as to shipment. Where tools are brought into Canada from points in the States this condition is particularly emphasized, owing to the heavy placement of Government contracts. In few instances will delivery be promised under six months and even then no guarantee is given. The uncertainty of the situation places the manufacturer in a position where a heavy overhead is necessary and production is far below the possible maximum.

Local plants, working on the larger American shells, are getting fair delivery on needed equipment, but not sufficient to meet all requirements.

Scrap Reaction Not Unlikely

Conditions in the old material situation are developing to the point when a downward tendency may be expected. With the bulk of the scrap business under the indirect control of the Imperial Munitions Board, the dealers are placed in a position more or less dependent on the wishes of the body. During the past summer small junk dealers have been very active in scouring the country for every description of old material that could be utilized as scrap, with the result that the yards of large dealers are well stocked with every variety of old metal material. Much of this has been disposed of at different intervals, but the inter-operation of munition manufacturers has eliminated a large portion of the business formerly carried on by the individual dealers. Considerable machinery is apparently accumulating, much of this being "cast-offs" from shell making plants. The scarcity becoming less pronounced and dealers are looking forward to lower prices.

The latest news has added to this belief, and as one dealer stated: "With peace talk abroad this kind of scrap will soon be a drug on the market."

PEACE TALK HAS NOT AFFECTED TRADE

Big Volume of Business in Sight—Supplies Sought for Manufacture of 155 MM. Shell

TORONTO — Dealers in machine tools, as well as firms engaged in making them are watching events in the war zone with considerable interest just now. Officials of the Canadian War Trade Board are in Washington this week. The mission they are apparently on has much to do with the future of the machine tool business in regard to munition plants. The peace move that has apparently shown its first signs of coming to life may have a decided influence on the situation. So far there is nothing to indicate that there is going to be any falling off in the business of making shells and munitions of war.

In fact there has been nothing to indicate that the first signs of peace—when they do show up in earnest—are going to have the effect of unsettling the situation to any extent. Dealers report that there is still a very keen demand for all sorts of equipment, and there have been no cancellations.

POINTS IN WEEK'S MARKETING NOTES

In order to conserve the supply of iron on hand in the yards of the makers of sewing machines, some firms are thinking of bringing out machines with wooden legs.

—

Peace talk has not interfered with the demand for machinery for the purpose of carrying out war contracts. The demand for equipment and supplies in connection with 155 mm. contracts is brisk.

—

There is a scarcity of light sheets in Toronto just now. Some of the dealers have nothing in their yards. This stock is used largely by the makers of stoves, builders of smoke stacks, etc.

—

Scrap metal dealers are not anxious to buy too heavily because users of scrap in many cases are having such difficulty in securing pig iron that they may have to greatly curtail or suspend their operations.

—

Tin plate mills have been operating at seventy per cent. capacity for some time, but the chances are that now that the canning season for perishable fruit is over this figure will be decreased severely.

—

American foundries are not making much progress yet with the manufacture of semi-steel shells.

—

It is estimated that Detroit has had since the beginning of the war at least $900,000,000 in war orders.

—

The big automobile industry in Detroit is working 75 per cent. on government war contracts now.

—

A slight reaction is noticed in the price of some of the war securities on the market, while those that will be in good shape for after-war trade remain strong favorites.

The Market is Firm

Light sheets are on the way up. They have passed the lowly 10 cents per pound mark, in fact some of the warehouses that are quoting this mark have none in stock, so they might as well quote five cents as ten. The houses that have light sheets are selling them out in nearly every case around 12½ cents, and there is nothing to show that the top has been reached in the matter of prices. The industries that are most affected are the stove makers, and the firms using much material for roofing. In fact there are a multitude of purposes to which sheets are put, and they are all more or less being put on thin edge by the scarcity and price of sheets. For a long time No. 10 gauge (140) was used almost entirely for the building of smoke stacks, etc., but for this purpose No. 11 can be used, which is ⅛ of an inch in thickness. No. 10 used to be about one half of the tonnage for stacks, tanks, boilers, etc., but it is hardly imported at all for this purpose now.

Firms entering the market for steel supplies are still finding that the going is poor. This week a large concern in the east applied to the War Trade Board for supplies for the finishing of a plant where chemicals were to be manufactured, but the Ottawa authorities seemed to have it figured out that it would be some time before they could produce any of the finished article. Their application for material on the embargo list was refused.

In a Queer Place

The scrap metal trade moves slow this week. Occasionally there are disputes over the prices quoted in this paper. Some dealers state that there is too great a spread between the prices quoted here and at Montreal. Montreal is a consuming point. The same can hardly be claimed for Toronto. The prices quoted for Toronto are net tons, and for Montreal gross tons. For instance, boiler plate is quoted $27 in Montreal against $20 in Toronto. The difference between a gross and a net ton is at the Toronto price, $2.40, which brings the Toronto price to $22.40 at once. Add freight of $4.48 and the price comes to $26.88, which is not far from the Montreal figure of $27. The figures quoted in the scrap trade are corrected each week, and are the prices that the dealers here will pay for scrap.

Some dealers that have quite a quantity of scrap for the market at times claim that bidding is keen for anything they have to offer. On the other hand the yards state that there is nothing that would encourage them to go ahead and stock up now, although they claim there is the material to enable them to do this. They claim that there are some users of scrap metal, in fact quite a number, including stove manufacturers, etc., who cannot get a supply of pig iron to mix with their scrap. They see that there may come a time when they will be out of the market for scrap because they can get no pig, and for this reason the dealers are not anxious to buy very heavily now. There has been no change in the prices.

Prices on non-ferrous metals show no change at all. There is a good volume of business offering and prices are firm.

Brisk Machine Demand

There is a good demand for machinery now. Peace talk has not made any impression or depression on the volume that is offering and being handled. The manufacture of the 155 mm. shell is taking a lot of attention and is causing a lot of inquiries for supplies to come to the dealers here. According to information from Ottawa there is to be a revival on a fairly large scale of orders placed here for the British government, as well as for the United States authorities. For various reasons it is not good to mention definite figures, but very reliable estimates place the mark at a good many million dollars per month.

U. S. WAR PROGRAMME GOING TO COME UP TO MAXIMUM FIGURE

Special to CANADIAN MACHINERY

PITTSBURGH, Pa., Oct. 10—Production of pig iron and steel has been increasing steadily since summer weather disappeared. The rate of pig iron production, which hovered between 40,000,000 and 41,000,000 tons a year from April to August inclusive, is believed to have crossed 41,000,000 tons, and may have crossed 42 000,000 tons. Production of steel ingots has gained in whatever proportion has obtained with pig iron, as steel production has been hingeing upon pig iron supply for many months past. Improvement in pig iron production is attributed to better weather conditions, with less atmospheric humidity, and to better quality coke being furnished, this latter development being due to the continued and strenuous efforts of the Fuel Administration. There has been little shortage of coke from a tonnage standpoint for several months past.

The official statistics of pig iron production in the first half of 1918 have just appeared, but give little news as to the total since that had been estimated very closely. The half-year's production was very poor. Output in the first quarter was far and away below the output in any quarter for several years by reason of the traffic blockade, which caused a coke shortage. Output in the second quarter probably made a new record for a quarter, but it was nevertheless quite below the rate capacity of the furnaces. Production as officially reported, in tons of 2,240 lbs., has been as follows:

	Tons
First half of 1916	19,619,522
Second half 1916	19,815,275
First half 1917	19,258,235
Second half 1917	19,362,981
First half 1918	18,227,730

From the first half of 1917 to the first half of 1918 there was a decrease in total output of more than a million tons. Production of basic iron was stationary. Foundry and ferro- silicon showed a slight decrease but this was a trifle more than made up by an increase in malleable iron, so that the net result was that the million ton loss in total output fell entirely on Bessemer pig iron. The showing is a remarkable one, for the foundries were not supposed to be particularly busy in the first half of this year, while steel making iron, both basic and Bessemer, was badly needed, and it does not look as if the blast furnace capacity was used to the best advantage.

Of late the authorities have been making a special effort to curtail the production and use of foundry iron in order to provide more iron for steel making. About a month ago a committee was appointed to seek cases of unnecessary consumption of foundry iron, the object being to shut off the consumption and either supply the foundry iron for making semi-steel shells or discontinue its manufacture in favor of one of the steel making grades.

The Eight-Hour Basic Day

It is well established that, since the Steel Corporation announced adoption of the basic eight-hour day, its adoption will be general in the iron and steel industry. The movement is going farther, however, for the Employers' Association of Pittsburgh, composed largely of foundry and machine shops, has decided to do likewise. In their case the increased wage cost will be relatively small as they do not have a great deal of time beyond eight hours. This association makes the proviso, however, that payment of time and a half shall be on the basis of 48 hours a week straight time, not on the basis of considering each day by itself.

The iron and steel industry has been working out details of application. There will be no double time, and as to regular Sunday work, it is probable that there will be time and a half for the first eight hours. There is much Sunday work that is of regular character, as in the operation of blast furnaces and by-product coke ovens, the men as a rule being given one day off out of the seven. Many men prefer that day to be a week-day rather than Sunday, and in such cases there is no occasion for a bonus for Sunday labor.

Steel Supply Short as Ever

While the War Industries Board has not yet completed its revision of the estimated total steel requirements for the half year, stated early in July at 20,000,000 net tons and later increased to 23,000,000 tons for certain and 25,000,000 tons as a distinct possibility, it now hints that the total will not be reduced. As reported in previous letters, there has been a strong effort to cut down all estimates wherever possible, even shell steel and ship steel being scrutinized to see if they were being furnished in larger tonnages than were being consumed. The intimation that the estimated total is not likely to be reduced does not mean, however, that there has been no opportunity found for curtailing in any direction. Rather it means that new wants have appeared that offset any reductions that may be compassed. For this, General Pershing seems to be chiefly responsible, his demands increasing right along. Probably there are also increased demands from Britain and France. Then the Railroad Administration has been calling for more steel, wanting more rails than the 40,000 tons weekly that have been furnished, and being desirous of placing orders for more cars in addition to the 100,000 ordered a few months ago, and which it is desired to get out of the way before the end of the year.

The Conservation Division of the War Industries Board continues to make agreements with various manufacturers who use more or less steel, with a view to limiting their operations. While these curtailments appear rather impressive, from the viewpoint of the commercial wares that will be cut off from the civilian population, they are not equally impressive from the viewpoint of the tonnage of steel they consume. It does not mean a great deal in point of steel tonnage, and it means much more in point of labor that will be saved in such factories.

Very little definite progress seems to have been made in the matter of arranging for quantity production of semi-steel shells. Foundries do not find that the technics of manufacture have been advanced to such a stage that the work can be undertaken with confidence.

Tin plate production is destined to fall rapidly. The order of a month ago that production be limited in the fourth quarter of 1918 to 70 per cent. of the production in the same quarter of 1917 is in force, but the limitations as to tin plate consumption are so great that nothing like the 70 per cent. could be made. By a general rule tin plate, apart from that bought by the government, can be used only for packing food products, this rule applying equally to the United States, Canada and South America. The perishable foods, however, are about done, and the Food Administration has been making arrangements with packers of non-perishable foods whereby their consumption will be greatly reduced, and the visible market is thus brought far below the 70 per cent. limitation.

BIG AUTO CONCERNS TURN TO WAR WORK

Estimated That Detroit Has Had About $900,000,000 in War Contracts

Special to CANADIAN MACHINERY

NEW YORK, October 10.—Steel companies, shipbuilders, manufacturers of guns, shells, aircraft motors and motor trucks, as well as the Ordnance Department of the army, have purchased machinery in the last week and numerous other contracts are pending. The greatest activity has been in the Central West, especially at Cleveland, Detroit, and Chicago. Most of the buying by interior manufacturers was at these points, but it is notable that New England tool makers received a number of orders from the Central West.

Government inquiries for war material calling for an expenditure of $50,000,000 are reported at Detroit, and as the work is largely for foundries, it is presumed that the prospective orders relate to semi-steel shells. It is estimated that government contracts thus far placed in Detroit alone call for the expenditure of $900,000,000, more than half of such contracts will be fulfilled by the end of the current year.

Turning to War Work

Automobile manufacturers have turned to war work with renewed vigor, and most of the large motor car companies are now operating 75 per cent. to 100 per cent. on war contracts. The Maxwell Motor Co., the Studebaker Corp., the Cadillac Motor Co., the Paige-Detroit Motor Car Co., the Liberty Motor Co., Dodge Bros., and 120 companies making motor car accessories are now operating 75 per cent. on government orders, while the Ford Co., the Packard Car Co., and the Hudson Motor Car Co. have their full capacity engaged on war work.

The Winton Co., Cleveland, which is manufacturing tripods for the large type of Browning machine guns, has purchased machine tools in the last week and is still in the market. With the installation of this machinery the entire capacity of the Winton Co. will be engaged on government contracts. The Doehler Die Castings Co., which is making parts of airplanes, is buying machinery for its Toledo, Ohio, plant. The Willys-Overland Co., Toledo, has purchased some tools and is negotiating for others which will call for an expenditure of $300,000 and which will be used in manufacturing 12-cylinder airplane motors. The machinery being purchased includes boring mills, lathes and milling and drilling machines. The government is now taking bids from Cleveland manufacturers on recoil cases for Davis guns for the navy, and the manufacturers in turn are inquiring for the necessary machinery.

It is estimated that between 300,000 and 400,000 tons of steel will be needed for the manufacture of motor trucks, the contracts for which were recently distributed by the government. Orders are now pending for 40,000 rear axles for type B army trucks, and with the placing of these orders additional machinery will be purchased. The American Can Co, which has large government orders for munitions, has purchased twenty screw machines for installation at its Toledo plant.

Canadian Business

The United States government has placed additional contracts for shells with Canadian manufacturers and an active demand for tools has resulted. It is reported here that most Dominion manufacturers are so filled with work that they are unable to accept orders for shell machinery. The Canadian shipbuilding industry is also expected to spend several million dollars for equipment and it is possible that some of these orders will come to the United States.

The Charlestown Navy Yard, which is about to make extensions, will require considerable machinery. The Newport News Shipbuilding & Drydock Co. has placed an order for cranes with a Cleveland manufacturer for its new boiler shop at Richmond, Va.; this buying is supplementary to the orders placed several weeks ago. The Ameriacn International Shipbuilding Corp. has purchased four cranes for the Hog Island plant. Crane inquiries have also been put out by the Wm. Cramp & Sons' Shipbuilding & Engine Building Co., Philadelphia., and by the Liberty Steel Products Co., New York.

The Ordnance Department of the army has placed contracts for large gun boring and turning lathes for the Nevilie Island ordnance plant and for the gun relining plant in France. It was found necessary to place these orders with manufacturers that previously had not made such tools but who have facilities for such work.

GOOD HOMES FOR EMPLOYEES OF BRANTFORD STEEL PRODUCTS

The plans of the Dominion Steel Products Co., Brantford, having in view the erection of a model village to be available for its mechanics seeking residence, are fast approaching realization. In Lansdowne Park a very desirable section, not far from the company's plant, quite a number of houses are in course of erection—several in fact approaching completion. The houses are in every sense substantial. They are of concrete foundation and built of hollow tile covered with stucco. The idea uppermost in many undertakings of this kind, when industrial concerns have sought to solve the housing problem—when the houses are much of the same type, with little thought of permanency, comfort, or attractiveness to the home builder—is here conspicuous by its absence.

The company plans the erection of one hundred houses, and these will be divided into seven separate and distinct types. The tract of ground for the purpose is sufficiently large to permit of these types being so arranged as to overcome any danger of monotonous similarity in the general plan. The lots have an average depth of about 150 feet and there will be no frontage of less than forty feet. Each house will cost about $4,000 to build. Each is a separate 7-roomed dwelling—that is there are no so-called terraces or semi-detached structures. It will be a section of which Brantford, or any other city, large or small, may well be proud, and one in which the better class of mechanic will find a home amid exceptionally inviting environments. The dwellings will be made available to the company's employees at cost.

The Dominion Steel Products Co. are at present engaged entirely on war work. After the war this huge plant will be organized as a permanent industrial concern.

PRODUCERS OF PIG IRON NOT ABLE TO KEEP UP WITH ORDERS

THERE is considerable speculation in regard to the pig iron market in the United States at the present moment. When the government authorities allowed an increase of $1 per ton on pig iron recently they also made the stipulation that future deliveries would be covered by that price no matter when the orders had been booked. A lot of firms have orders that have been standing for weeks and months at the furnaces, and now if they are anxious to secure deliveries at once they will have to come along and pay the additional cost. If they are not willing to do this why the furnaces can refuse their business. Reports from some of the larger points in the United States are as follows:

Pittsburgh.—It is believed that September production will make the best showing for several months, and as many furnaces which have been down for repairs or for relining, will go into blast within the next few weeks; it is thought likely that the present month will make a record.

Buffalo.—The increase that has been granted on pig iron does not seem to satisfy the furnace men in this district. They point out that the increase in the price of ore of 25 per cent. per ton will take 50c of the $1 increase per ton of iron and that the rest of the $1 will be taken up by increased labor costs. One thing that has been keeping back production as much as anything else has been the very inferior quality of the coke that has been sent to the furnaces here for some time past. There has been an improvement in this lately since a drastic action has been taken by the government.

Cleveland.—Firms that have any pig iron in their possession are being welded up by the war authorities and are being made to pledge that this material will be used for war work and nothing else. A circular letter now being sent to the producers by the committee of Pig Iron. Iron Ore, and Transportation, calling upon the trade to secure these pledges from their customers.

St. Louis.—Deliveries here are excellent and the war plants are all working at capacity. Little comment is made on the increased price in iron here as the consumers are so anxious to get material that they are willing to pay anything within reason for it.

Chicago.—Some of the users of pig iron in this section are going behind in their deliveries all the time. This is accounted for by the fact that government allocations come along and make large inroads on the stock with which they had intended to fill the orders booked. In fact one of the largest makers here states that his plant right now is 150,000 tons behind their schedule on regular contracts. He also stated that it would take him at least two months to recover this ground. This same situation is quite common all over the district.

ENGINE BUILDING ON PACIFIC COAST

In a recent issue of this paper an article appeared entitled, "Vancouver Firms Pool Engine and Boiler Orders."

In the course of this article, Mr. McCulloch was quoted as stating with regard to the building of engines, that on the smaller types they could compete, but on the larger ones it would be difficult. In fact it had not been undertaken.

We are informed by Mr. A. F. Menzies, who is now in Ottawa representing the Wallace Shipyards, of Vancouver, that the construction of large marine engines and boilers has been undertaken and well carried out, and is proceeding very successfully. The following list of engines already built and in course of construction by this company remove any doubt on the matter:

S.S.War Dog, 1,350 I.H.P., now at sea.

S.S. War Power, 1,650 I.H.P., now at sea.

S.S. War Storm, 1,650 I.H.P., under construction.

S.S. War Cayuse, 1,000 I.H.P., now at sea.

S S. War Atlas, 1,000 I H.P., ready for trial trip.

One steamer, 1,000 I.H.P , under construction.

Vessel No. 100, 1,800 I.H.P., under construction.

Vessel No. 106, 1,800 I.H.P., under construction.

Two engines of 2,500 I.H.P.,, plans in hand.

The next size to be undertaken will be of 3.000 I.H.P.

The boilers for the above vessels are being constructed at the Vulcan Iron Works, Vancouver, and this firm are also building boilers for the vessels under construction at the yard of the J. J. Coughlan & Sons, whose boiler shop was recently destroyed by fire.

The foundry of the Wallace Shipyards Ltd. has furnished all the iron and brass castings for the above vessels, excepting the first two. The foundry has also turned out a number of propellers for the Imperial Munitions Board, and one large manganese bronze propeller for a coast steamer. From the foregoing it will be seen that engine and boiler building on the west coast is an accomplished fact, and we are pleased to correct the impression given by our previous article.

MANY ACTIVITIES GOING ON IN THE ST. JOHN DISTRICT NOW

Work is being pushed on the new wooden steamer, "War Digby" in the Grant & Horne yard, Courtenay Bay.

In the Marine Construction Company's yard, Strait Shore, Mr. D. H. Saker has a large four-masted schooner framed up. The work is progressing rapidly.

The C.P.R. has extended its grain conveyor on the west side in anticipation of an enlarged traffic during the coming winter.

The Eastern S. S. Corporation has renewed its lease of the city wharves at Reed's Point. The landing pier has recently been placed in thorough repair.

The government wharf below the Atlantic Sugar Refinery, destroyed in a recent gale, has been restored.

Repairs have been made to the government railway track at Courtenay Bay

The pier on the north of the West Side ferry slip has recently been rebuilt by S. H. Mayes, contractor for the city.

The Imperial Oil Company are hastening the completion of their three-storey brick warehouse at Barrack Point. The new building will have a very comfortable office equipment.

The Booth Sardine Fisheries have added a large boiler room to their building plant. This corporation is now well equipped for sardine packing.

The replacement of St. David's Presbyterian Church destroyed by fire in December last has been begun. The new structure will be a creditable one. It is the intention to place the school building in the rear instead of in the basement as before.

The Roman Catholic school building on Cliff street is almost complete, and in the fall will be occupied by schools. This building is one of the handsomest and best equipped of the school buildings of the city.

Golding and Starret, Ltd., with a capital stock of $5,000 and head offices at Petersville, Queens County, has been incorporated for a lumber and pulp business.

The Bealgrave Mines and Development Co., Ltd., with a capital stock of $78,000 has been incorporated for the purpose of carrying on a coal business in Queens county.

The Kay Engine Company has been incorporated at St. Andrews to promote the construction and sale of the Kay engine.

A movement is on foot to accelerate the development of the coal mines in Kent county.

FREIGHT ON MATERIAL FOR BOAT IS $80,000

High Figures That Ship Yards of the Pacific Coast Have To Work Against

A. F. Menzies, of Vancouver, representing the Wallace Shipyards, Ltd., of North Vancouver, has been in the east for a few days, having been called to Ottawa in connection with new contracts for vessels under the order of the Dominion Government. The Wallace yards have practically completed the work they had under way for the Imperial Munitions Board, but they have preparations well under way for going ahead with their other construction work. The Wallace yard had a launching on Saturday last, which was most successful. The "War Storm" being put into the water. This was a steel vessel of some 4,700 tons. The engines were h.p. 25, i.p.41, l.p. 67. and 45 stroke, developing about 1,650 horse power. The ship yards with which Mr. Menzies is connected are gradually working into the construction of ships of larger size, and berths are now prepared to take care of construction up to 8,100 tons.

As a general thing the coast yards do not build the machinery for the boats they make, but at the Wallace yards this is all done. They have had very good success in their foundry and all through, having cast about 17 cylinders without losing one. Very little difficulty is experienced in securing all the raw material that is necessary for the foundry or machine shop work. The boilers used are the output of the Vulcan Iron Works, at Vancouver.

To a question as to whether it paid to build the machinery at the coast, Mr. Menzies replied "we build the engines because we cannot buy them. Of course, the freight charges work against us there, and they run into a lot of money on a steel vessel, when all the plate is hauled to the Pacific coast from the rolling mills of the United States. On some of the ships we have made the freight on the material will run from $75.000 to $80,000."

Mr. Menzies has spent some time at Ottawa in consultation with the officials of the Marine Department, going over details in connection with some of the new orders the Wallace yards are taking on for the Dominion Government.

McAvity Plant Growing.—The McAvity machine plant, Marsh road, St. John, N.B., is rapidly developing into one of the largest enterprises of the kind in eastern Canada. The 400-foot unit, which was completed in such record time in 1916, has recently had a unit of similar dimensions added to it and this is being quickly filled up with machinery. But even with this enlargement the firm are not satisfied, for within a few weeks the erection of another large foundry building has been begun on the southern end of the company's lot near Westmorland road. Grant & Horne, who constructed the original unit have the contract for the later additions.

Making of Files Used to Be All Hand Work

Interesting Features of an Important Piece of Work—Just Now the Securing of Material and the Making of Files is Proceeding Under Cramped Circumstances

By DONALD A. HAMPSON, Assoc. Mem. Am. Soc. M. E.

The first of this article appeared in the issue of CANADIAN MACHINERY of October 10

CUTTING

FILE teeth are cut in machines which drive a chisel into the blanks with great rapidity, moving the bed on which the files lie at a rate according to the "pitch" of the teeth—in file parlance, according to the "cut." Some files are cut by hand but the number is negligible, and it is predicted that the practice will die out with the present generation of file cutters. There are two general types of files cutting machines in use: the Weed, an English machine, and the Hess. The latter is more complicated but does the very nicest kind of work and is fast—it is not so well adapted to the larger files such as a machinist uses in his daily work because of structural weaknesses inseparable from the design.

The two photographs show Weed machines of different sizes—the first has a "hammer" of but 2 pounds weight, while the larger one has a 40 pound hammer. The hammer carries at its lower end a chuck, B in Fig. 4, in which the chisel is fastened; the weight of the falling hammer together with the reaction of a compressed spring drives the chisel into the file. At the back of the machine in Fig. 13 will be seen a pulley; this drives the main shaft which has at its inner end a two or three-lobed cam that raises the hammer and compresses the spring that many times for every revolution and allows the drop between every raise.

In Fig. 14 is shown the details of that part of a file cutting machine that in machine shop practice would be termed the carriage and carriage feed. The solid black represents two flat file blanks laid on the swivel bed C that can rock in the slide G but is confined longitudinally by shoulders which may be seen in Fig. 13. Should the files be slightly uneven in section or the chisel not ground squarely across on the bottom, this swivel bed instantly adjusts itself under the blow and the cut produced is of the same depth at each edge of the files. The slide G is an accurately finished casting fitting the planed V in the base of the machine. The base of the machine is solid and the blow is delivered right over the center; with this base set on a foundation of cast iron and concrete there is formed the finest kind of an anvil for hammer blows—the parts G and C are of a form that is self compensating for wear and that rigidly builds up the anvil to the working level.

FIG. 13. MODERN FILE CUTTER

The cut is started at the point of a file and runs toward the heel—this means that the working parts travel away from the operator, the travel being by power. Figs. 13 and 14 show this mechanism. A cross shaft at the rear of the machine is belt-driven from the main shaft. Bevel gears deliver the power to the buttress thread screw at the side of the machine which moves the slide when the half nut F is engaged. To start the feed (and the cut on a file), the operator presses the nut against the screw; to stop the feed two methods are employed; one is to use a trip which disengages the nut quickly, and the other is to shift the main driving belt to the idle pulley on the back of the machine, which is the method used on the machine in Fig. 13, where part of the throw-off may be seen below the pulley. On the smaller machines the workman shifts the belt by a hand fork at the end of the cut. The slide is returned to the starting position by raising the nut and pulling back by hand.

To make the return easier the V cut in the bases of the larger machines is at an angle of about 15° with the horizontal. Lubrication of these V's, some of which are as big as on a 48 in. planer, is by oil channels and a squirt can just as with a planer. The pounding that the beds get sets the moving parts pretty close together and tends to break down the oil film, and the workmen show signs of fatigue after pulling back on them for several hours. It was found that by putting a wedge-shaped piece in the clearance space in D and allowing the slide to ride on this at the end of the stroke, the slide was raised enough to break the grip of the suction created and the parts traveled much more easily.

Belt drive has been found most satisfactory for file cutting. There is enough flexibility in it to take care of the momentary stoppage of the bed every time the chisel cuts into a blank. To cut coarser or finer teeth on the same machine the pulley on the cross shaft is changed and the belt length altered to suit—some of the commercial forms of V-belt lending themselves to such changes very nicely. Another and better arrangement for changes is to use an idle pulley with a swinging arm that may be set to take up the slack without altering the belt length. In larger shops and where possible, a machine is kept set up for one cut of file and kept so. In this connection it must be noted that the pitch of the teeth for each so-called cut varies with the size of the file—thus a 14 in. bastard file will have coarser teeth than an 8 in. bastard file.

The feed screw and nut are important parts of the machine and do quite heavy work. Ball thrust bearings are now used on the screw to relieve the shoulder of the pull of the cut and are very satisfactory. A babbitt nut is used for cheapness of renewal and to take the wear from the screw itself. Fig. 16 shows a portion of the screw and of the method of babbitting the nut. It is obvious to a mechanic that the nut can best be babbitted right on the machine if perfect alignment would result; it is also obvious that, being a top half, the nut is a hard one to pour. One shop settled the question by making a mold for each cutting machine. This mold, as seen by Fig. 16, is a lower half nut which completely fills the threads up to a horizontal center line; it also has heads at the ends making pasteboard and putty unnecessary. Placing the mold against the under side of the screw the nut is brought down on it and the two joined by a C clamp. Then all that is needed is a ladle of babbitt. The pouring holes at the top and the retaining heads of the nut casting hold the babbitt securely in place.

Due to the changing cross section, files do not lie well on the bed of the machine and some sort of a seat has to be built up for them so that they are solid under the chisel blow. Babbitt and zinc are the materials used for the purpose. At one time babbitt was freely used and the beds were made hollow on top and filled up to a working surface but increasing attention to small economies and the rising cost of babbitt have cut down its use three-fourths. Present practice makes use of the cast iron bed, shaped on top to the type of file being cut and overlaid with a strip of zinc. Thus a half round depression is formed for the back of half rounds, a V cut is made for three square files and a small half round groove for round files—in these cuts the zinc strip, 1-16 in. to ⅛ in. thick, is pened and then fastened with a screw or clamp. As these are worn out they are renewed and the old ones salvaged at the scrap price. Square and rectangular shaped files are laid directly on the bed with the strip of zinc under them; to allow for working variations this strip is cut perhaps a quarter inch wider than the file, and if this excess is good when the center is worn out, it is trimmed off and used under the edges of blanks which are having the teeth cut on the edge.

Fig. 17 shows a round file and how a bed of babbitt would be arranged under it. Fig. 18 shows a babbitt bed under a file set for edging. The better way with both the foregoing would have been the solid cast iron with zinc facing. Cast iron itself would answer every purpose

FIG. 19—A SPECIAL FILE

for the first cut but the facing puts the wear on a renewable piece. And after the teeth have been cut on one side it is policy to use every means to protect them.

On the bed of the file cutter there is screwed near the operating end a piece of steel with a taper notch corresponding to the tang of the file. This acts as a vise for the tang end during cutting. The point end, and in fact the entire file is kept from rebounding by a "pressure foot" which acts directly in front of the line of cut. How this works is shown in the details of Fig. 15 which shows also the first tooth cut. This pressure foot is connected to a slide controlled by the lever shown at the left

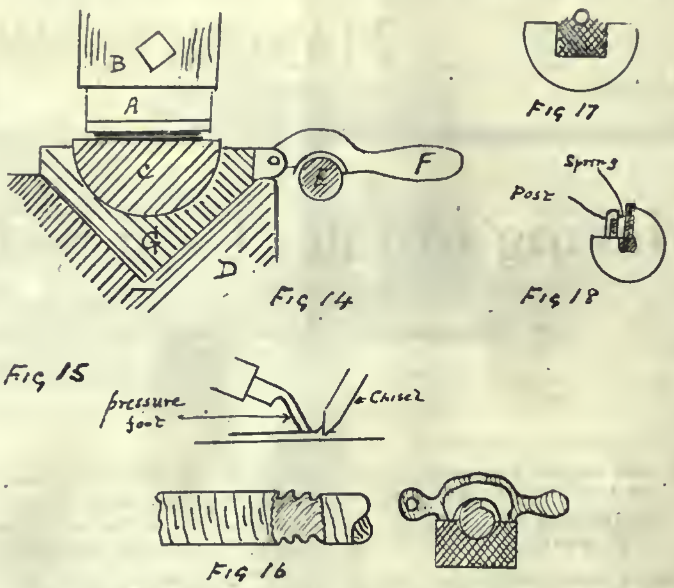

FIG. 14—DETAILS OF PARTS. FIG. 15—HOLDING DOWN THE BLANK. FIG. 16—SCREW AND METHOD OF BABBITTING. FIG. 17—ROUND FILE ON BED. FIG. 18—HOLDING TO CUT EDGES.

in Fig. 13, which lever is weighted to give the desired pressure for the size of file at hand. By means of a foot treadle the slide is raised for removing the file.

The actual cutting of even the largest files takes but a few seconds for each side. A skilled cutter handles the files very rapidly, turning them after one side is cut and doing the second or third side before piling on his bench. Though most machines will be found cutting one file at a time, on production work two and three are now the order of the day. Fig. 14 shows two flat files side by side, covered by a wide chisel. When cutting the flat side of half rounds, the swiveling possibilities of the back are taken advantage of and three are set in a three-grooved bed with a sufficiently wide chisel to cut out all at once.

Because of the increasing thickness toward the heel the blow of the hammer has to be regulated so as to cut a constant depth of tooth. It is for this purpose that the hand wheels are put at the top of the machines. These wheels are sometimes dished to bring them to a convenient working position—the operator keeps a hand on the wheel all the while, and, with a skill that is cunning moves it to produce the perfect file. The hand wheel turns a screw that compresses the heavy coil spring and produces a deeper cut. A cylindrical block of rubber is used instead of a spring on smaller work.

Round files require a dozen or more cuts. So cut, their surface is really a succession of flats. It is these numerous cuts that add to the cost of rounds. This cost has been reduced somewhat in shops that have standardized their shapes by using less skilled labor and, by means of limit stops for travel and a form which automatically changes the blow instead of doing it by hand, getting the same quality of work as before.

Etching is a method sometimes used for round files of the better grade. Still another method which produces a superior file is to cut a spiral like a thread the entire length, doing it with the same chisel-driving mechanism—this cut in distinction from the other, whose cuts meet but approximately. The spiral cutting is done by a device which bears a resemblance to universal milling machine fixtures for cutting spirals, i.e., turning the file while the bed is advancing at a predetermined rate. The file so produced is commercially round and can be used for the best class of work.

On the broad side of flat files the cut needs to be varied but little because the total difference in thickness is only about 1-64 in. to each side, but when it comes to rounds and tapers and the edges of flat shaped files, the difference may be as much as ¼ in., and much variation of the blow is required to produce an even cut throughout the length. It is here that the eye of the cutter must work synchronously with the hand, or with her hand, for women have been taking the place of men in file work for the last few years and have done very well.

When cutting the teeth on the edges the files are supported as shown in Fig. 18 by resting against a vertical side cast on the bed and having a light flat spring set in the post as shown, pressing the blank up to the side. Sometimes there is no retaining piece used, and again a strip is screwed to the horizontal face forming a shallow groove in which the files are dropped. Two and three files are cut on edge at a time on the less particular grades.

There are hundreds of cutting machines in some of the larger plants and every machine uses one chisel when it is running, besides which the cutter usually has several other chisels allotted him for different cuts. With so many of these tools the necessity of some system of grinding them is evident; if every man left his machine idle and went to a distant grinder for sharpening even once a day the loss would be considerable to say nothing of the loss resulting from every man grinding according to his particular ideas. The most satisfactory way is to have a tool boy collect the dull chisels twice a day, taking them to the tool room where they are ground on a tool grinder which is arranged with set fixtures to make every chisel of the same class alike on the cutting edge. A sharp chisel is given in return for a dull one and each man gets his chisels on check just as machinists get tools from tool rooms by check. The amount of money tied up in a few thousand chisels of expensive steel is worth the effort to keep track of them.

Cutting is a piecework job as are many of the other operations on the file. The cutter gets paid say twelve cents a dozen for 10 in. mill files. The blanks are given out to the workman maybe thirty or forty dozen at a time from a distributing crib and he must return the same number when he is finished—if one or two or three are spoiled in cutting no deduction is made, but if a man habitually spoils a greater number he is charged with them. A defect in cutting that does no harm except as to appearance puts the file in the "second" class, and it is hardened separately, packed, and sold under another name. An odd feature of the piecework price is that the large file pays less than the small one, the coarse one less than the fine. The reason is clear when we consider that there are more teeth to the inch on the smaller files of the same cut and with all finer cuts it is necessary to keep the chisels in better shape and take more care to get uniform teeth—on an 18 in. bastard file for instance a slight variation in the teeth would escape the notice of all but the expert, and it would do no harm anyway.

Stripping

There is an operation preceding the cutting that must be mentioned. It is called "stripping." Machinists would call it "draw filing," for that is really what it is—the file blanks are draw filed after they come from the grinders by using regular files either in a machine or doing the work by hand. In the vernacular of the trade, stripping "opens the surface" of the file (which may be more or less rolled down by grinding) as well as smooths the file generally, levelling off possible high spots and removing burrs. The broad side of flat shapes and of half rounds are done in stripping machines where a number of blanks are laid side by side on a working table which is given a limited side movement at the same time that the overhead file is passing back and forth throughout the entire length. The sharp corners of square and flat shapes are draw filed to remove the keen edge and to take off the metal that, if left on, would create a projecting edge at each corner as the teeth were thrown up by the chisel working on the side and the edge both.

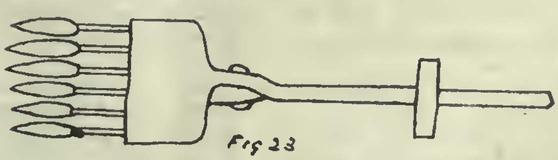

FIG. 23—TONGS TO HOLD SIX SMALL FILES.

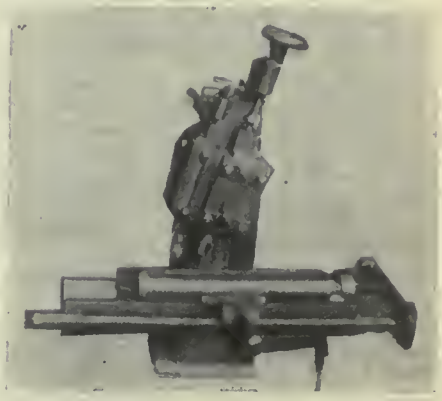
Hand Cutting

Hand cutting is still practised to some extent, chiefly on specials. The long-



SMALL FILE CUTTER.

fancied advantage of hand cut files for regular machinists' use was in the irregularity of the tooth spacing. Theoretically they would cut faster and smoother because the teeth would therefore not create chatter marks; also not so many touching the work surface at a time, the file would take hold better and remove more metal. These supposed advantages have been pretty well discounted because it has been proven that a man quickly tires when he makes a "hand planer" of himself; try as he will he cannot remove metal as fast as a machine, because a file properly selected for the work will do smooth work, and if the dies are made of the right shape to give the files the taper and belly no trouble should be experienced in filing straight and in removing any reasonable amount of metal. Irregularly spaced teeth have been and still are made—a conventionalized hand cut, as it were—but for the reasons above stated such a file is not worth the extra trouble of manufacture and most manufacturers have discontinued making them. The name "increment cut" is applied to such files.

Fig. 19 shows a special file. This would be made hand cut because of the relatively small quantities needed and the peculiar shape which would necessitate special rigging up. It is much like the common toolmakers' files but is made double ended with teeth on the flat of one end and on the edge of the other, leaving a safe edge either way. An expert cutter would get about fifty cents a dozen for cutting these at before-the-war prices, and he would cut teeth that run forty to fifty in an inch of length, fine work for toolmakers even at production speeds!

The cutter is aided in his hand work by the sense of touch. In Fig. 20 is shown a file with a few teeth cut and the chisel ready for another tooth; it will be noticed that the edge of the chisel rests against the raised part of the tooth last cut. This accounts for the regularity on fine work. Many of the so-called

Swiss files are hand cut—a skilled man will cut a 2 in. (surface) file on both sides in thirty seconds. Even this rapid work, however, is bettered a hundred per cent. when the work can be done on a machine.

Marking

Aside from inspection and stamping on the name, the file is now ready for hardening. Some shops persist in stamping

FIG. 25

ing their name on with a hammer and a hand stamp simply because those in charge have never seen it done any other way. The time lost and the cost of quickly battered up stamps is a heavy loss. Marking machines of the Slate variety are slow for this kind of work unless power driven. Some form of punch or press is the quickest kind of marking machine. A No. 18 Bliss press is plenty heavy enough—and a second-hand one is good enough—for marking files; the hand stamp is fastened in the ram instead of a punch and the machine belted to run about 20 r.p.m., at this speed the foot treadle can be blocked "down" and the machine runs slow enough to enable any ordinary workman to feed the files one at a time without trouble.

A most excellent marking machine has been made from a discarded file cutter. The drawing, Fig. 26 shows one of these converted machines—it has all the desirable features for this purpose, i.e., the blow is not limited in its travel and thus the machine is not stressed if a too thick file is put in it, and a thin file would be marked just as any other (which would not be the case with the punch press), the bed on which the files are laid has a self-adjusting arrangement that makes it very desirable for both flat surfaces and taper—the latter encountered when the name is marked on the tang, and the machine can be instantly set to deliver a light or a heavy blow.

Too light a machine should not be selected for this use, but there are found at times in all plants medium-sized or heavy cutters that have become so worn that they do poor work, and it is thought advisable to replace them. If the adjusting screw will hold the compression of the spring as the cam raises the hammer, wear in the other parts of a Weed machine will not make a great deal of difference. The head is swung to an upright position, the slide should be screwed or blocked so it cannot shift, and a hardened anvil set in directly under the blow. Then strips to suit the tang or heel of the files—adjustable for different sizes—are fastened to the bed. The expense of overhauling the vital parts of an old machine is not great, and when so doing the overhanging base and the long bed can be shortened, which, with the removal of unused parts gives a neat appearing machine.

This form of marking machine is really a drop hammer procured at little expense. As to the necessary weight of the hammer, this can be computed from the total length of line in the stamped name and the penetration desired; a heavier hammer can be made and put in a light machine but the additional parts required for the stamp and holder often make up enough. To prevent undue wear and tear, a stop is provided as shown, tripped by the foot treadle that holds the hammer up except when tripped, the cam within meanwhile simply revolving. Depending on the size and kind, from four to six hundred files can be marked in an hour's time.

Hardening

The universal practice is to heat files in a lead pot for hardening. Files are hardened only, not drawn as the machinist knows the term; in reality there is a certain amount of letting down the temper, for the files are taken out of the quenching bath before they are cold. In bygone days egg coal was used to heat the lead, but this is now obsolete, fuel oil or gas having taken the place of coal, oil being the more generally used. The saving of space, of fuel, and of attendance with oil or gas, to say nothing of the closer regulation, allow no comparison to be made with coal.

The files before hardening are coated with some preparation to keep the lead from sticking in the teeth. Whiting and wood alcohol is one of the commonest preparations though, due to the present high cost of the latter, water is now used extensively for the mixture—the water dries a little slower. Helpers or boys dip the files in the mixture and stand them up to dry, standing them against heated racks. It is highly important for the safety of the hardeners that there be no trace of moisture on the files when dipped. One of the most efficient arrangements for this work is a conveyor using a wire mesh belt, power driven, with the loading position close to the coating tank and the delivery at the lead pot. During its travel the belt passes through a gas or steam heated oven that is kept at a predetermined heat for the assured drwing of the coating; the speed of travel is also variable if necessary. This arrangement delivers the maximum number of files and does it without taking up any storage space at either end, the speed of delivery being subject to change by the hardener if for any reason he is retarded in his work. Saving in handling and in danger of the files getting bruised will soon pay for such an improvement.

The files are suspended in the lead by driving them in handles that in turn are suspended from cross pieces over the pot. The hardener always has a sufficient number ahead to give all a chance to heat thoroughly and slowly. Under the best systems two men work in a team and harden in the neighborhood of 300 dozen medium-sized files in a day, one man doing the dipping and the other the straightening. The old fashioned way was for one man to do both these operations, and while he did them well and rapidly the production was far less, due to the extra movements he must make. Under present systems it is considered better to let a helper place the working handles on the files before the hardener gets them and to remove them when the straightener is through.

The lead is of course kept at a red heat. Its surface is covered with pulverized charcoal or other substance to keep it from oxidizing. In connection with the conveyor scheme detailed above a saving in fuel was discovered in the files being so warm as they were plunged—a file as warm as could be held in the hand would not chill the lead to the extent that one at atmospheric temperature would—the heat required to raise the file to a drying temperature was saved and utilized, making the process one of pre-heating as well as drying.

Salt water is used for quenching the heated files. It is a medium that has not yet been superseded. The brine is made very heavy; salt is addd to the water until it will absorb no more. This heavy quenching bath cools better than water alone because it does not fly away from the plunged file as does the lighter medium; it makes better contact with the file just as the liquid lead in the heating pot makes a far better contact than would the coals of a fire.

Files are subject to bending or warping in the cooling bath just as other articles of carbon steel and for the same reasons, though system and quantity production and supervision have eliminated to an extent many of the causes of warping against which the hardener of a few odd pieces must battle. The straightener has been mentioned and his duties are to correct the worst of the crookedness which occurs after due precautions have been taken in manufacture, delivering a file that is commercially straight.

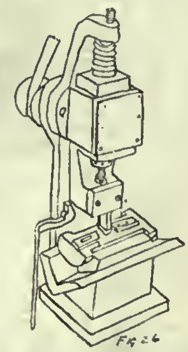


FIG. 26—A FILE CUTTER CONVERTED INTO A MARKING MACHINE.

To the machinist, the idea of straightening a piece which is glass hard and not drawn seems an impossibility. It is a trick of the file trade, and so well acquired that the straightener rarely breaks a file. While the file is yet warm, before it entirely ceases to sizzle, it is withdrawn and quickly inspected; if a crook shows up the file is bent the required amount and cooled in a way that will fix this shape permanently. For this purpose the workman uses a flat brush which he dips in his tank of water and applies to the side of the file that he wishes to contract. The usual method of bending is shown in Fig. 21; two bars are fastened across the top of the tank or near to it so that the file may be thrust between them and pried downward at the tang end, the concave side of the file having been turned uppermost.

Half round files are the most troublesome in hardening because of the unequal area of surface on the face and the back. To overcome this the hardener bends the file slightly as in Fig. 22 before he dips it in the brine, an amount which his experience tells him will be needed to counteract the "draw" of the greater cooling surface on the back. Another trick with half rounds is to plunge them in the brine, not straight down but with a circular motion that brings them out of the liquid at its end, the pocket of brine within the circle and above the file having less cooling effect than the body below the file.

Various improvements and kinks increase the production of the hardening department. Thus the smaller sizes, of which the special in Fig. 19 is typical, are held in groups for suspension in the lead and while being quenched. As shown by Fig. 23, special tongs with wide faces are employed that hold in this case six files at a time. A ring over the handles secures the files for the entire cycle and relieves the workman. The jaws are faced with rubber or cork or leather to provide the yielding necessay to holding the several pieces. Over 300 dozen of such files have been hardened both ends in a day by an expert.

A continuous hardening machine has recently been tried out in one plant and bids fair to be a distinct success. It is built on the station principle—loading station where the files are hung from arms so they are in the lead, a period of travel during which the file gets thoroughly heated, and an unloading station where the hardener takes the files off the arms with his tongs and dips them. The arms are driven by a central retaining spider rotating about a vertical axis. Each arm has a certain number of snaps which the loader opens to get the files in and which the hardener touches to release them. So fast does the hardener "turn 'em out" with this machine that two or three straighteners are kept busy on that final operation. Gang dipping on machinists and toolmakers' regular files is not attempetd. Every steel man knows the value of slow, thorough heating of an article to be hardened and the files in this machine get all of that. The files are grasped so they travel edge to the lead, so set and traveling at the slow speed they create almost no more disturbance of the molten lead than would an equal number of files simply submerged.

Going into the subject as a matter of research it has been found that files given a more extended heat treatment will do more work before wearing out than the files of manufacture. All of us are familiar with the qualities imparted to gears and other motor parts by successive heating and quenching and drawing, with the higher elastic limits resulting, the increase in wearing, and the wonderfully fine grain as shown by micro-photographs. Files are made from high carbon steel and to an extent partake of the qualities named when properly treated. These points were noted in connection with files when users reported that re-cut files gave better service than new ones—re-cut by softening, grinding off the old teeth, re-cutting and re-hardening. The refining of the second heat is now held responsible for this, a conclusion borne out by tests with new files that have been heated and dipped a second time and have then stood up much longer. The buying public however is not ready to pay the extra cost.

Clean and Pack

Following the hardening the files are cleaned. The hardening process leaves a very slight oxidization and there is a little grit left from the coating, all of which must be removed to make a neat appearing file. Stiff brushes are used for some of this work but the great volume of files are cleaned in a steam cleaning device which shoots a spray of steam, water, and a little of the finest sand against the surface of the files. The apparatus is something like a sand blast—a metal casing protects the workman and confines the spray and is supplied with an overhead exhaust; a door in the front is so placed that the jet strikes the files as they are inserted one at a time and as fast as they are put in, turned over, and taken out when they are cleaned. Sulphuric acid is used for cleaning and sharpening to a limited extent.

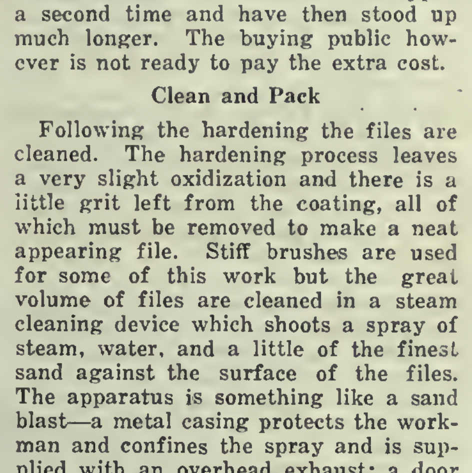

FIG. 27—SKETCH OF HARDENING MACHINE AND HOW WORK IS HANDLED.

Immediately after cleaning the files are oiled to prevent rusting. Then they are wrapped in manila paper and put in boxes. Efficient methods are followed in this seemingly ordinary operation and a marked economy of time and wrapping paper is effected. Instead of rolling the dozen files in a long strip of paper completely enclosing them and forming more than one thickness at a number of places, paper coming in perforated rolls is used. The distance between perforations is equal to two sides and one edge of a file, it will therefore protect four flat surfaces, to say nothing of the one edge. This paper is drawn out over the box which is resting on the bench in suitable guides and a file is dropped in the center of each space; the perforations break as the file reaches the bottom and its sharp corners cut the already partly severed strip. Another packing that is used in these days of paper shortage is to lay pasteboard strips between the files as they are placed in the boxes—this is quick and all sufficient as the sides of the box are ample protection for the file edges. This method is economical and quick.

Rasps

Rasps are made of a low grade of steel, primarily because steel of higher carbon will not stand the bending and compression which a rasp tooth must without breaking. So low in carbon is this steel that only the thin points of the teeth harden at all but this is sufficient for the work rasps have to do. Fig. 24 shows rasp teeth in perspective and in section. They are cut with a round nose chisel—this leaves a half round gouge in the flat surface of the blank and the metal thus thrown up forms the tooth, the end of the chisel making the straight side.

Formerly rasp teeth were cut by hand by the workman who sat before a bench on which the blank was strapped down and who used a hand chisel which he drove by a sort-handled hammer having a peculiar bludgeon-shaped head weighing several pounds. The workman spaced the teeth by eye, experience enabling him to turn out a wonderfully regular piece of work. Needless to say, he worked slower at this job in the afternoon than in the morning, and the physical powers of a human being limited the production. In the days before the wide use of the automobile there was a big demand for horse rasps, and it was a profitable branch of the business; the rows of men engaged in cutting rasps were later replaced by the rasp cutting machine.

Fig. 25 shows the principle on which this machine operates. The blanks are held much as are file blanks, and the table travels under the chisels in much the same manner but the table travels between the uprights of the machine, and there are two of the half round chisels held in the chuck, producing two teeth at one blow. By a side movement the whole of the width of the blank is covered. In Fig. 25 the heavy shaded part is the blank. Reference to the left hand figure shows that the head travels in curved guides—this gives the teeth a little more or the throwing-up cut imparted by the hand cutter.

With hand cutting, rasp teeth naturally varied a little in height, nor is this altogether eliminated in the machine-cut article. Where the best of work is turned out a higher price is gladly paid for rasps that have been evened off, as a single high tooth will score quite badly and necessitate further dressing down of the work. This evening-off process is done like cutter grinding—just the tops of the teeth are touched by the emery wheel and these are given about 15 degrees of clearance. The work is done on a grinder specially constructed for this purpose, an index finger rests against the row of teeth being levelled off and a slide on which the rasp lies is an easy fit in ways that allow slide and rasp to be moved by hand. Rasps so bettered sell for $1 to $1.50 more than the run of the shop.

In connection with prices at the present time, a comparison with those of a decade ago is interesting. The steel alone now costs more than the retail price of the files then. For instance, 14 in. flat files once sold for $2.50 a dozen Twenty-one pounds of steel went into their make-up—hardly a profit for handling the steel, you say, let alone paying a cent towards the bigger item of manufacture, but at that time the best of file steel cost only 3 to 3½ cents a pound!

NAVIGATING INSTRUMENTS USED ON AIRPLANES

Before an airplane can be put into military service it must be equipped with nine or more delicate aeronautic instruments, some of which are absolutely essential to exact flying, and all of which contribute to the successful operation of a plane. Without them a pilot would soon lose his location as to height and direction; he would not know his speed through the air, the speed of his propeller, the amount of gasoline in his tank, the temperature of his cooling water, or if his oil was circulating He could not tell whether he was banking properly on his turns. These comprise the necessary flying instruments, but an aviator could not fly to any great height without another valuable instrument, an oxygen supplying apparatus, nor could he operate his guns, signal headquarters, release his bombs, or "shoot" his cameras without additional mechanisms.

Two Sets Sometimes Necessary

All these instruments must be ready for installation on the airplanes as soon as they are assembled, for no plane is complete without them. In some instances, particularly for the two-seaters and the heavy bombing machines, two and even three instruments of each sort are necessary, totalling sometimes as many as 23, but for ordinary work only about nine of them are needed. The average cost of a set of navigation instruments for a single plane is $350.

For operation of actual combat planes, such as observing, photographing, bombing, and fighting planes, many other complicated and expensive instruments and sets of apparatus are necessary. Among them are machine guns, gun mounts, synchronizers, bomb racks, dropping devices, bomb sights, radio, photographic, and oxygen apparatus, electrically heated clothing, lights, and flares. The cost of such additional accessories would bring the total cost of equipment for a plane to several thousand dollars each, depending upon the type of plane. But these devices will not be discussed in detail here.

Foreign Models Improved Upon

When the American air programme began to be developed none of the instruments now so vital to the service was being produced in quantities, and some of them were not being produced at all. Over 60 per cent. of these instruments had to be developed from foreign models, and the remaining 40 per cent. was secured by modifying or remodeling American automobile-type instruments. Numerous and serious difficulties were encountered in designing instruments, capable of quantity production, of the lightest possible weight and under exacting requirements as to accuracy. During this pioneer work new instruments were being developed abroad almost daily, each new design carrying an improvement.

Most of the work in this connection was done by the Signal Corps in conjunction with manufacturers. All available information and data were collected, foreign and domestic models and types were carefully tested, designs were standardized, and specifications prepared. Results show that types for every class of instrument have been adopted and put into production here. Far greater standardization has been reached than exists in Europe to-day, tending to increase quantity production materially and decrease the number of replacement parts necessary.

Some of the Instruments

Various instruments developed by the Signal Corps include:

The tachometer, or revolution counter, is an instrument which indicates the number of revolutions per minute at which the engine is running. Unlike the speedometer on an automobile, it does not translate revolutions into miles per hour; another instrument gives the speed in relation to the air. When instrument matters were taken up last July there were no tachometers manufactured in this country of the type which has proven most successful abroad; namely, the escapement or chromatic type. Two large manufacturing companies are now turning out these instruments in large quantities, one of them 100 a day, and a third company has also in production a new centrifugal type.

The Air Speed Indicator

The air speed indicator is a pressure gauge for showing the speed of the plane in relation to the air, not the earth. This instrument includes what is known as a Ventuvi-Pitot tube, which is fastened to a strut and takes in the air from ahead. The air sets up a corresponding pressure in an auxiliary tube, which is calibrated and indicated on a dashboard recording pressure gauge.

The altimeter is an aneroid barometer graduated to read height above the earth instead of pressure. Under standard specifications a reduction in weight and size was effected in the manufacture of these instruments, which are now being produced in large quantities and of a quality equal to the best foreign make. Three standard types are made, with ranges of 20,000, 25,000 and 30,000 feet. Production was up to 500 a week in April.

The Airplane Compass

The Airplane Compass.—After much experimental work this instrument has not yet reached the perfection desired. A new type, having advantages over any present form of compass, especially as to compactness, is now used. In the development of this instrument effort has been made to reduce the weight to the safest possible minimum and to decrease the space required in the airplane. One concern is now turning out compasses at the rate of 200 a week.

Airplane Clocks.—Due to the development which had been made in clocks for automobiles, it was only necessary to standardize a design of mounting in order to adopt such clocks to airplanes. Sufficient quantities are now available for all needs.

Pressure Gauges.—Instrument-board pressure gauges were already manufactured here in large quantities, and as soon as standard specifications were developed production started. Two types are used, one to register the air pressure which forces the gasoline to the engine and the other to show the pressure produced in the oiling system by the oil-circulating pump. Standard forms of cases and dials with interchangeable glasses and bezels have been designed.

The Radiator Thermometer

Radiator Thermometer.—This instrument is mounted on the instrument board where it indicates the temperature of the cooling water in the engine. Undue heating shows that the engine is not running properly or that more water is needed. Thermometers of this type made here were, and still are, being submitted to extensive tests. Efforts were also made to stimulate the trade toward developing more accurate and reliable instruments, and now a sufficient supply is available from two sources.

Banking Indicator.—This is an instrument used to show when a plane is correctly banked in making a turn. Spirit level, balance, and gyroscopic types are being used. The problem of indicating the extent to which a plane is inclined to the horizontal in the air is a very complicated one. No simple solution has yet been reached. Fortunately, it is not often necessary to determine whether the plane is exactly horizontal, except in connection with bomb dropping. Development work is under way which it is hoped will lead to improvement of devices already in use abroad.

Aldis Sight.—This sight, which is used in connection with fixed guns firing through the propeller, has been copied, as regards its optical features, from an English instrument; but the construction has been modified in such a way that the behavior of the instrument in actual use will probably be very much improved. After a number of tests and experiments satisfactory instruments are now available. The makers have been assisted in recomputing the lenses to suit the optical glass available in this country. The illumination of these sights for night operation is also being studied.

Research the Mainstay of a Nation's Industries*

The National Research Laboratory of England Has Been a Potent Factor in Overcoming England's Industrial Handicap and in the Placing of Her Scientific Work on a Par With Germany's—The Author, in a Paper Delivered at the Royal Institution, Describes the Organization and Some of the Work it Has Accomplished

By SIR RICHARD T. GLAZEBROOK, C.B.

SOME seventeen years ago I spoke in this room on "The Aims of the National Physical Laboratory." I endeavored to make clear the reasons for its establishment and to indicate some of the work we hoped to accomplish. I concluded: "It has been my wish to state in general terms the aim of the laboratory to make the advances of physical science more readily available for the nation and then to illustrate the way in which it is intended to attain these aims. I trust I may have shown that the National Physical Laboratory is an institution which may deservedly claim the cordial support of all who are interested in real progress."

Much has happened since then: how far we can assert that we have made good is for others to say. At any rate our growth and the generous aid we have been given by many valued friends is evidence that the support for which I asked has not been wanting. And now that another great change in our position is about to take place and, as I trust, a wider sphere of usefulness is offered to us, it is not unfitting to put on record something of what has been done and to indicate, though it must only be in general terms, plans for the future. "Plans for the future": to-day it is hard to plan; one thought only fills all our minds, and every effort is needed to secure that victory without which future plans are useless.

Statistics

Let me commence, then, with a few statistics as to growth and work: In 1901 the staff consisted of three scientific assistants working in some small rooms at the Kew Observatory, and the old observatory staff; the income was perhaps £5,000. When I lectured last arrangements were in progress for moving the laboratory to Bushy House, Teddington. To-day—or rather from April 1 next—we shall be organized in eight different departments, each with its own superintendent and a large staff of scientific assistants and observers. The staff now numbers well over 500 persons, of whom about 180 are women. The expenditure during the current financial year will be considerably above £100,000. Quite recently several acres of ground adjoining the laboratory have been secured and large additional buildings are being erected; these are required for urgent war work.

Many of these have been erected by private generosity. Thus, Sir A. F. Yarrow gave £20,000 for the William Froude National Tank, Sir Julius Wernher erected the Metallurgical Laboratory at the cost of £10,000, Sir John Brunner gave £5,000 to the Electrical Laboratory, while many friends—including the Royal Commissioners of the Exhibition of 1851—contributed to the administration block (Fig. 1) and the Optical Laboratory erected in 1913 at a cost of £20,000.

FIG. I. THE ADMINISTRATION BUILDING OF THE NATIONAL RESEARCH LABORATORY.

As to finance, it may be of interest to give some figures. The ordinary expenditure—excluding sums spent on capital account—increased from £5,479 in 1900 to £38,003 in 1913-14, the total income from January, 1900, to March 31, 1914, being £282,545. The sources of this income were distributed thus:

Treasury grants to the laboratory	£80,500
Treasury grants for aeronautics	20,182
Receipts for work done	166,633
Donations	15,230
	£282,545

During the same period the capital expenditure was £156,198, provided thus:

From Treasury grants	£75,941
From private donations	55,967
Provided out of income	24,290
	£156,198

The enormous growth in expenditure from £38,000 in 1913-14 to over £100,000 this year is, of course, due to the war.

The growth of the personnel has been already alluded to. On the executive committee the changes have been numerous. Of the original members, all of whom gave untiring work towards the promotion of our interests, we have lost Sir Courtenay Boyle, Sir John Wolfe Barry, Sir Edward Carbutt, Dr. Elgar, Sir Andrew Noble, Sir W. Roberts-Austen, and Sir Arthur Rucker, while, in addition, from the names of the original general board the following are missing: Lord Kelvin, Sir William Huggins, Sir Michael Foster, Professor Ayrton, Dr. L. Mond, Sir William Preece, Sir Joseph Swan, and Sir W. Wharton. Sir John Wolfe Barry's recent death will be felt as a severe loss, not only to the laboratory, where he was welcome as a wise councellor and a real friend, but to all the numerous institutions with which he was connected. We are happy in having Lord Rayleigh stil las our chairman; his hand has steered us through many difficulties, and to his consistent support much of the success is due.

Growth

During this period the ultimate control of the laboratory has rested in all particulars with the president and council of the Royal Society. They have been responsible for the finances of the institution. Any loss—I am glad to say there has been no loss—would have fallen on the funds of the society; the laboratory, in spite of its name "National" has really been a private concern of the Royal Society, supported most cordially throughout by six of the leading technical societies, and dependent for part of its income on a grant-in-aid from the Treasury, but in the main from the receipts from fees.

From April 1 next there is to be a change. The scientific control of the

FIG. 2. THE ROLLING MILL.

laboratory is still to be exercised by the president and council of the Royal Society the property of the laboratory is to be vested in the Imperial Trust for the Encouragement of Scientific and Industrial Research—it is now vested in the Royal Society. The income of the laboratory, including receipts from fees, is to be vested in and is to be under the control of, the committee of the privy council for Scientific and Industrial Research. The laboratory will be managed by an executive committee appointed as heretofore and containing representatives of the great technical societies. In this manner it is hoped to secure financial stability and to retain at the same time the great benefits which have come from the close connection with the Royal Society.

In the future, as in the past, the laboratory will endeavor to discharge two functions; it will be a laboratory of industrial research, and a national testing institution or proving house. To-day we deal with the Laboratory of Industrial Research.

Industrial research—What is it? In recent years much has been written on this subject; the idea of a laboratory devoted to industrial research is by no means novel, and the steps by which ordinarily a scientific discovery develops into a manufacturing process are generally recognized. First and foremost we have the research student impelled by his thirst for knowledge, his desire to penetrate ever deeper into the mysteries of nature; he does not work with the deliberate intention of making something of service to humanity. Faraday's discoveries of electromagnetic laws, made in this building, were at first as useless as the new born babe, but had within them that power and potency which has transformed the industry of the world. Rontgen, when he discovered X-rays, or J. J. Thomson when he tracked down ions and corpuscles in the manner he has often demonstrated here, thought little of their application to surgery and the countless benefits they have brought to suffering humanity.

There must be institutions where research work is carried on for its own sake, where—to apply Sir J. J. Thomson's recent remark—men may make discoveries which may revolutionize and not merely reform the world, where they may train students in those fundamental laws and principles which must be at the root of every successful endeavor to apply science to industry. But there is a wide gap between such homes of science and the works of the manufacturer, and it is to fill this that laboratories of industrial research are needed.

Optical Glass

Abbe realized in 1876 that British optical instruments had reached the highest development possible until a radical change was made in the properties of the glass used for lenses; it took years of patient labor, aided by subsidies from the Bavarian government, before he and Schott were able to place Jena glass on the market. Von Bayer discovered synthetic indigo about 1880, but it was not till twenty years had passed that the Badische-Anilin-Soda-Fabric produced it on a commercial scale. Long and patient inquiry was needed in the great laboratory of the General Electric Company, of America, at Schenectady before the Coolidge tube was developed from the original X-ray tube. The work of the discoverer needs development and extension before it can be utilized by industry. This is the task of the Laboratory of Industrial Research.

Or. again, looking at our problem from the opposite side, a manufacturer has some question to solve—the utilization of a waste product which if it were not waste would make all the difference between commercial failure or success, the discovery of a material with some special properties—e.g., a light alloy of great strength at a high temperature—needed before a new machine can be completed. Such a man must have access to a laboratory fitted and equipped for the purpose with a trained staff having stored experience as the result of previous work or researches on cognate questions. Let me try to indicate some of the methods in which the National Physical Laboratory has endeavored to fulfil these duties.

Three of the researches referred to in my earlier lecture related to the production of optical glass, the work of the Alloys Research Committee of the Institution of Mechanical Engineers, and the measurement of wind pressure on various structures and surfaces. On all these subjects much has been done. It was some time before the authorities could be persuaded that in neglecting to study the production of optical glass in England they were adding seriously to the risks and dangers of war. Many years ago a strong committee, formed under the chairmanship of the late Sir David Gill, took the matter up and laid before the government a scheme for a complete study of the problem. Nothing was done until war taught us the need of attending to key industries, but since then real advances have been made, not only at the laboratory but elsewhere also, and some of the more serious difficulties of the problem have been overcome; it is hoped that in the near future it may be possible to introduce changes of procedure which will greatly simplify the process of manufacture and lead to an increased output. Closely bound up with this is the study of the properties of refractory materials used in furnaces and elsewhere.

Microscopy

The application of the microscope to investigate the mechanical properties of metals and alloys was comparatively in its infancy in 1901 when I called attention to the then recent work of Professor Ewing and Mr. Rosenhain on slip-bands. At the laboratory the study of alloys, principally perhaps the light alloys containing large percentages of aluminum, has been almost continuously pursued first by Dr. Carpenter and now for some years past by Dr. Rosenhain. The various reports of the Alloys Committee of the Institution of Mechanical Engineers must be referred to by those who wish to estimate the importance of that work; it is not too much to say that nearly all the alloys of aluminum now used in the production of aircraft are its outcome. A list of the important papers dealing with this subject presented to the Advisory Committee for Aeronautics would fill many pages of this lecture and our knowledge has been immensely increased thereby. It must not be inferred from the foregoing that the metallurgy of the light alloys is the only branch of the subject which has been studied at the laboratory. A large number of "special investigations" have gone in the various departments. By the term "special investigation" is implied some inquiry into a particular subject made at the instance, maybe of a government department or of a private firm, e.g., the investigation into the properties of a new material or the cause of failure of some machine or process such as a boiler plate, the crankshaft of an engine, or an autogenous weld. For example, the failure of one of the main roof trusses of Charing Cross Station some years ago led to an interesting inquiry into the strength of welds. Thus, certain aspects of the metallurgy of steel have received very full consideration.

But it is sometimes urged: "Why do you need a special laboratory for such work? Can it not be done equally well in one of the university or technical college laboratories? Is it not enough to multiply and organize these, to bring the teachers into direct contact with the manufacturers of their districts and to encourage the students at an early stage to interest themselves in the scientific problems they will have to solve later in their daily work?" To this my answer would be that it is not enough. The primary work of the professor is to teach and to advance knowledge, that of the student is to learn how to research and to apply his knowledge. The professor will, no doubt, keep in close contact with the industry and take his illustrations from the manufactures of his district, but before his students can usefully engage in industrial research they must have a thorough grasp of the principles underlying all research and of the methods of employing them. Industrial problems are usually too complex for students, and, moreover, the answers are wanted too rapidly to make them subjects of a student's exercise; he will learn by failures; by the inexperienced the right road is only found at last after many tempting tracks leading nowhere have been vainly tried. The manufacturer who comes with a problem which cannot wait will be more sure to find a solution if he applies to men whose daily work is to attempt such problems and who have the experience of the past to guide them. Moreover, the plant and equipment required is special; the industrial research laboratory must be fitted on the industrial scale. A rolling mill is not an adjunct required in every technical school where the principles of metallurgy are taught, and yet without a rolling mill (Figs. 2 and 3) the study of the light alloys at the National Physical Laboratory could not have been brought to the pitch it has been. The plant and equipment of an industrial research laboratory are provided for the purpose of applying science to industry. The requirements of students and the educational value of the apparatus need not be studied. There must, of course, be many specialized laboratories of industrial research; much more than the National Physical Laboratory is required. I will return to that point later. At present I merely wish to urge that university and technical college laboratories cannot fill all our needs.

And now let me come back to another illustration of the industrial research done at the laboratory closely connected with our original work on wind pressure. The Advisory Committee for Aeronautics was first appointed in 1908 by Mr. Asquith, as Prime Minister. It owes its inception to Lord Haldane, and much of the experimental work which it has initiated, and which has had so marked an effect on the efficiency of British aircraft, has been carried out at the laboratory. At present there are five air channels (Fig. 4) in practically continuous use, and more are being erected. Some years ago I gave some account of the work by which Bairstow and Busk, starting from Bryan's theory, had solved the problem of stability. It is impossible to tell at present of the progress made since that time, but when the day comes on which the tale can be told it will form a striking example of the work of a Laboratory of Industrial Research, and the results obtained for purposes of war will bear fruit in the rapid progress of civilian aircraft.

Froude Tank

The Froude tank is another department of our Laboratory of Industrial Research (Fig. 5). Built by Sir Alfred Yarrow in memory of Mr. William Froude, and for the service of the nation, he has had the privilege of seeing it repay its cost many times in the services rendered to naval warfare, while the pages of the Transactions of Naval Architects bear eloquent witness to the value of the work Mr. Baker has done for naval architecture generally. I could multiply instances. Perhaps I have said enough to justify the claim that, though with scanty means, we have been a Laboratory of Industrial Research of real value to the nation. In my former lecture I quoted a cynical remark made in regard to an advertisement for staff. It ran: "The scale of pay is certainly not extravagant. It is, however, possible that the duties will be correspondingly light." The first sentence is still true: the staff have falsified the inference.

FIG. 3. THE ROLLING MILL.

And now, turning to the future, let us consider what is to be the position of the institution as a central laboratory of industrial research.

In a lecture delivered in Birmingham rather more than a year ago, shortly after Lord Crewe had announced the formation of the Department of Scientific and Industrial Research, I referred to such laboratories, and I wrote:

"There must be more than one; in many cases an industry can be best served by a laboratory near its principal centre. Large firms, again, may each prefer to have their own trade secrets —this must be so to some extent—and trade jealousies may interfere with full co-operation, but a private laboratory on a really sufficient scale is expensive; too often it becomes little more than what I have called a works laboratory for testing the products of the factory, and for the smaller firms, at least, the only way to secure the full advantage of scientific advance is by co-operation —co-operation in the laboratory, co-operation, with specialization in production in the works themselves."

It has been suggested that I wish to make the National Physical Laboratory not merely a national, but the only bridge between science and industry. This is not the case; let me quote, in order that I may amplify them, the concluding words of the lecture:

"Associations are to be formed representing various trades or industries; the representatives of these will discuss with representatives of the advisory committee and other experts questions needing scientific investigation and, when these are determined, the grant, supplemented in most cases by funds raised privately or contributed by the industry, is to be used to carry them out. Such work needs laboratories, and it is here, it seems to me, that the future of the National Physical Laboratory lies. The lord president spoke in generous terms of the work of the laboratory in the past; its many friends who heard him were grateful for his cordial recognition of our labors, and he indicated a sphere of wider usefulness under less difficult conditions in the future. Let me picture to you what I trust that sphere may be.

FIG. 4. THE SEVEN-FOOT WIND TUNNEL.

"In many cases, no doubt, the researches contemplated must go on in special laboratories arranged and equipped for the purpose—laboratories closely connected with the industry it is desired to help, situated at the great manufacturing centres; but there are many other researches of wide interest and great importance for which a central laboratory is the proper house, a laboratory fitted and equipped in an ample manner, with a trained and competent staff animated like those, my colleagues, who have built up the National Physical Laboratory, with a love for science and yet withal with a keen appreciation of the practical side of the question discussed and a real desire to help our country by the application of science to industry.

"The body controlling industrial science research must have access to a laboratory in which may be studied the many problems which do not require for their elucidation appliances of the more specialized "works" character, or opportunities only to be found in particular localities: where a staff is available, able and experienced, ready to attack under the advice of men skilled in industry, the technical difficulties met in applying new discoveries on a manufacturing scale or to develop ideas which promise future success.

"Such a role the National Physical Laboratory should be prepared to play, such is the future which I trust may be in store for it."

This work has already been begun. The various trades associations have been formed, or are being formed, for the promotion of research on matters of interest to the members of the trade.

Objects of an Association

The principal objects of an association, as they would be laid down in the memorandum of association, may be briefly summarized thus:

(a) To promote research in connection with the manufacture and use of . . . by maintaining or subsidizing existing laboratories and workshops, or, if necessary, establishing and equipping laboratories and workshops.

(b) To retain or employ skilled professional or technical advisers in connection with the objects of the association.

(c) To encourage the discovery of, and investigate the merits of, improvements which may seem capable of being utilized for the purpose of the respective industry, and to take out patents or licences relating to such inventions or improvements and to perfect and develop them.

(d) To support or to establish libraries, collections, or museums necessary for the promotion of the industries concerned.

(e) To publish or to assist in publishing any literature, statistics, or information relating to the subject of . . . that may be of value to members of the association.

(f) To promote in any way desirable the education of those engaged or likely to be engaged in the industries concerned.

(g) To co-operate with other associations or bodies having objects bearing on the work of the association.

(h) To apply to the government for, and to accept, grants of money and other assistance for the purpose of the objects of the association and to discuss and negotiate with the Department of Scientific and Industrial Research and other government department's schemes of research and other matters within the objects of the association.

Each such association will probably require its own laboratory situated, for preference, at the centre of the trade concerned. This will deal with the special problems of the trade, problems which need intimate association with works conditions for their solution and for which the close supervision of men in works is important.

Objects of a National Laboratory

But there are numerous industrial problems which can best be dealt with in a central laboratory; let me give some instances of what I mean. Such, for example, are:

(1) Investigations into methods of standardization or of measurement generally.

(2) Investigations into the physical and mechanical properties of materials used in many trades.

(3) Investigations useful to a trade which has no fixed centre, but is widespread over the country.

Or, again (4) a central laboratory will be of service as a means whereby information as to large questions of general interest, investigated either at the central laboratory itself or at the local special laboratories, may be circulated and time saved by placing at the disposal of any special laboratory requiring them the results obtained elsewhere.

Taking these heads more in detail. I will postpone the consideration of No. 1—standardization problems—to my next lecture. It is sufficient to remark here that the work already done in this direction has been very great, and to point out that unification of standards used in various trades is highly desirable and can only be secured by the existence of a central standardizing institution working in close co-operation with local institutions.

Light Alloys

Turning, then, to (2)—investigations into the properties of materials used in many trades, the work done on light alloys affords a good example of this, work for which the British Aluminium Company have recently shown their appreciation by sending a generous donation of £500 to the funds of the laboratory. They write as follows:

"The board of directors of the British Aluminium Company, being desirous of showing their appreciation of the research work that has been, and is being carried on at the National Physical Laboratory, in connection with light aluminium alloys, and with a view to assisting towards further work awaiting accomplishment in the same direction, have unanimously voted a donation of £500 to the funds of the laboratory.

"A cheque for that amount I have pleasure in enclosing.

"My directors do not wish to make any special conditions attaching to this donation, other than that they desire it to be applied, as and when opportunity offers, towards research in connection with the development of light aluminium alloys, leaving it to your discretion to determine the exact application of the grant, whether as to the provision of instruments and plant, or technical supervision, or in any other direction which may commend itself to you."

"I take this opportunity of expressing on behalf of my board and myself, our satisfaction with the results which have so far been achieved, and our firm conviction that, given time and suitable conditions, still further and material advances will follow in due time, from which material benefit should accrue to industry."

Problems for Research

Or, again, the following are a few of the problems which it has been recently stated need solution to satisfy the needs of one important industry:

(1) An investigation into the physical properties of alloy steels.

(2) An investigation into the conditions affecting the flow of liquid fuel through an orifice with reference to:

(a) Proportions of orifice.

(b) Temperature of fuel and air.

(c) Viscosity of fuel.

(3) An investigation of the stress distribution in irregularly-shaped members —crankshafts and the like.

(4) An investigation into the wear of bearings.

(5) Investigations into the material suitable for valves, cylinders, and other parts of internal-combustion engines.

(6) The efficiency of radiators for such engines.

(7) An investigation into the cause of the lubricating properties of oils with a view of framing a specification for such oils.

It is obvious that the results of all these investigations, while of special importance to the automobile industry, are of great interest to others. Any of them could go on in a properly-equipped laboratory, while it is clear that to carry out many a very complete physical, and in some cases chemical, equipment is needed.

And that leads to another very important point. A special laboratory, if it is to be really of use, must be complete. Many of the investigations just indicated involve thermal and electrical measurements of high accuracy. Elaborate apparatus is involved and a skilled staff to use it. These conditions can only be satisfied if the laboratory possesses a large and varied staff, capable of advising on each special point as it arises, and the necessary outfit of delicate and expensive apparatus. In many instances the difficulty lies in the development of the method of measurement and the calibration and standardization of the apparatus employed rather than in the actual experiments.

Refractories

Or, to take another instance. There have been some conferences lately with regard to research in refractories, and it was clear that there is much work to be done and ample opportunity for the development of research in special laboratories in close contact with the industry, whether at Sheffield, Middlesbrough or South Wales, for steel making and other metallurgical processes, or in the Potteries for the china and earthenware trades. It was clear, too, that there was much work which could best be done at a central institution such as the National Physical Laboratory. Such work, for example, would embrace:

(a) The investigation of the following physical, physico-chemical, and mechanical properties of refractories under service conditions:

Thermal conductivity.
Electrical conductivity.
Thermal expansion.
After expansion and contraction.
Softening point (with and without load).
Thermal endurance.
Crystallography.
Texture (grain-size).
Porosity.
Density.
Permeability to gases.
Penetration by molten metals.
Mechanical strength.
Hardness.
Resistance to abrasion.
Resistance to chemical action.

(b) Standardization of tests and formulation of specifications in each class of material.

(c) A study of the properties of all refractories and metallic oxides associated with them, up to the highest attainable temperatures, with special reference to their physico-chemical transformations.

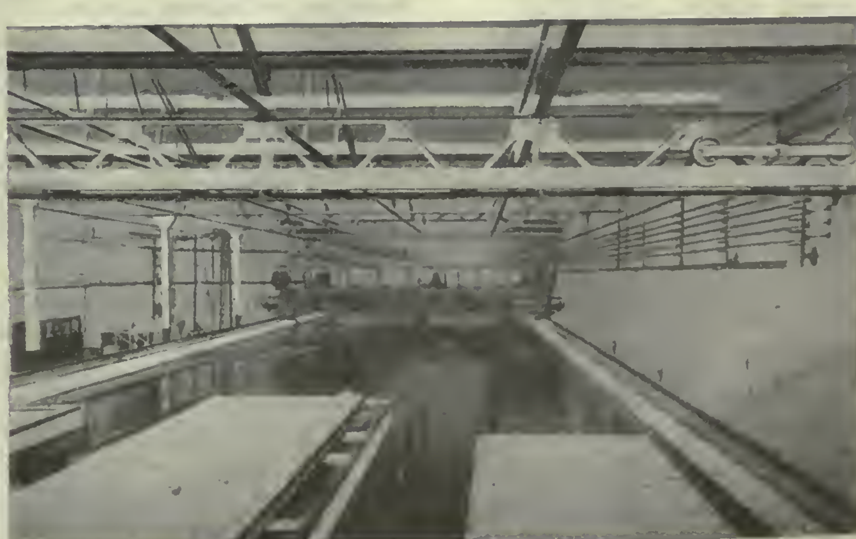
(d) Development of micro-technology as applied to refractories.

(e) A special study of the rarer refractories.

As instances of (3)—Investigations useful to a trade which has no fixed centre—I may give the following:

1. A research has been in progress for some time at the laboratory into the heating of buried cables carrying electric currents. In connection with the Wiring Rules Committee of the Institution of Electrical Engineers much has been done to determine the temperature to which the cables used in house wiring are raised in various circumstances, and to fix the safer currents to be used in each case. Our knowledge of the temperature reached in cables when buried in the ground is very scanty and somewhat conflicting; much depends on the nature of the covering used to protect them, and possibly something on the nature of the soil. Cables laid in ducts, again, differ from those protected merely by the ordinary forms of lead or other covering, and yet the life of the insulation depends in great measure on the temperature reached when the current is flowing and thus regulates the carrying capacity of the cable. Thanks to the co-operation of supply authorities in many parts of the country much valuable information has been collected, and, though the research at the laboratory proceeds but slowly, results of great importance are being obtained. Such a research needs large appliances, and currents up to 8,000 amperes or 10,000 amperes will be employed. It needs also the resources of a fully-equipped physical laboratory in order to measure accurately the temperature differences due to varying conditions; when complete it will be of value to all supply companies. This is true of many other electrical tests and experiments; the results are of wide application; it is desirable that they should be widely published.

The building trade offers another example of this kind. Brick and stone, wood and iron, have been used for long, and their properties when employed for building construction are generally well known. This is less true of other more modern materials—ferro-concrete, for example. There are rules—based no doubt on the best experience available



EXPERIMENTAL TANK FOR SHIPS MODEL TESTING

—for estimating the strength of beams, columns and floors, but there is much scope for inquiry. Accordingly, at the instance of Sir John Cowan, of the firm of Messrs. Redpath, Brown and Co., who is bearing the expense, apparatus is bein built to test columns up to 15 ft. or 20 ft. in length and floors of considerable size. War conditions again are interfering, but the work is progressing slowly and must be done. There are other materials besides ferro-concrete urgently calling for examination. Nor is the strength of the materials the only factor to be considered. Materials transmit heat in very varying amounts and the comfort of a house, to say nothing of the cost of living in it, will depend on whether it is possible easily to keep it warm in winter, cool in summer. Recently we were asked to compare the heat losses from two enclosures exactly alike in all respects, except that the one was roofed with corrugated iron, the other with some preparation of asbestos. It was found that the latter cooled 20 per cent. faster than the former; the loss of heat depends, in part, on the conductivity of the material, in part on the emissivity of its surface, and the superior emissivity of the asbestos sheet more than made up for its inferior conductivity. In this connection it is clear there is much to be done, and for such work a central laboratory, with proper equipment, is the most suitable place. Arrangements are in progress by which it is hoped many of those questions will be thoroughly investigated.

Little need be said as to the fourth section of the work suggested for a National Industrial Research Laboratory.

The importance of the collection and dissemination of information on matters connecting industry and science is clear. At a central laboratory much of the information will be to hand; the accumulated experience of the staff, their knowledge of the work done in the sectional laboratories, their appreciation of the bearing on industry of inquiries in the region of pure science, are all valuable assets and a proper organization only is needed—by means of a bulletin or in some such way—to circulate their information where it is most wanted.

There is ample room for a central laboratory without trenching in the least on the spheres of the local sectional institutions. If the Department of Scientific and Industrial Research is to carry out effectively the work it contemplates such a laboratory is essentiol, and my hope is that the National Physical Laboratory may develop into such an institution in close connection, through the department, with local laboratories throughout the country.

One word in conclusion. The workman is worthy of his hire. In the past the scale of pay has certainly not been extravagant, and there is no call for extravagance in the future, but the remuneration offered must be sufficient and the conditions of work fair. Much has been written lately as to the inadequate remuneration of scientific workers, whether teachers or the expert staff of laboratories and factories, and it is realized, I trust, that the time has come to cange this for men and for women alike. To-day there is a great demand for scientific workers, and while, as in other walks of life, commercial life must offer greater prizes than government service, it is essential, if the necessary work is to be done and the workers retained, that the emoluments of technical posts under government, and the conditions attached, should be as good as those of the regular administrative staff of the civil service. This must apply not merely to the heads of the various institutions, but to the rank and file on whose labors success depends. This point I need not labor here, but in pressing it I feel confident I shall have the support of all who appreciate the importance of science to the nation.

USE OF METAL SUBSTITUTES

The *Norddeutsche Allgemeine Zeitung* publishes the first of a series of articles on the numerous substitutes which the British blockade has compelled Germany to use. It is claimed that the problem has been solved with great success. It is impossible to publish full information until after the war; at present only bare indications can be given. When the blockade isolated Germany, three possible methods of adjusting her metal supply to her metal demands presented themselves: a strict economising of the stocks held, the use of substitutes, and the rearrangement of engine and tool production in accordance with the new circumstances. All these three methods were adopted.

The electro-technical inductry suffered most by the shortage of copper; and, as in the engineering and shipbuilding industries, it had to content itself with zinc alloys containing 4 per cent. to 5 per cent. of copper or 2 per cent. to 3 per cent. of aluminium. In railway and tramway carriages, cast-iron and zinc replaced copper for door-handles, brake-handles, etc. Zinc was also used instead of copper and nickel for buttons, shoulder-pieces, and other decorations on military uniforms.

The optical industry before the war worked almost entirely on brass and aluminium. In place of aluminium it now uses an alloy of magnesium and aluminium, called Elektron Light Metal, which is lighter and firmer than aluminium. The watchmaking and toy industry was likewise badly hit by the metal shortage. There was a danger lest its stoppage should throw thousands of workpeople out of employment, and it became urgently necessary therefore to reorganise it on the basis of substitute metals. At first the watches and toys were plated with copper or brass in order to give them their old appearance. But, before long, even this was found impossible, and people had to content themselves with "field-grey."

After copper, tin was one of the most important metals for which substitutes had to be found. It was used principally for bearings, white metals, and soldering. If no substitute had been discovered for the bearings with 70 per cent. to 80 per cent. to tin, the whole of the munitions industry might have been in danger of stoppage. The situation was saved by zinc alloy and by alloys of calcium and lead. For white metal likewise a substitute had to be found, especially as tins for conserves of all kinds play a very important part in time of war. Other metals, and especially prepared lac, have been adopted as substitutes, while for soldering purposes cadmium has been found suitable.

The metal shortage, and more particularly the shortage of brass, has also been felt in the manufacture of scientific and technical instruments, where brass was used in plates, wire, tubes, and shaped pieces. The whole industry has had to be reorganised, and time and money have been spent in adapting the work to the new conditions. But all this has not been without gain, for many substitutes have been discovered which are likely to be retained after the war. The only necessary condition is that the iron should be malleable, a condition, however, which, in consequence of the scarcity of materials and skilled workers, is hardly ever fulfilled. Iron and steel bars and steel tubes have come to be relied on; but zinc has become the principal substitute for brass. Zinc plates, spherical zinc, and zinc tubes are very much in use; and since zinc by itself is not suitable for working up, excellent zinc alloys have been turned out, only slightly inferior to brass. Naturally, the problem of protecting the surface assumes a very different aspect when iron or zinc is used instead of brass. It has become necessary to plate the surface of the parts with brass, nickel, or (since nickel is also becoming scarce) cobalt. Mostly, however, the zinc parts are given a dark tinge and then covered with a serviceable lacquer. In pre-war days fine instruments looked bright and shiny in their brass; to-day they are dark, opaque, even black, and not seldom field-grey.

The hope is expressed that iron and zinc will continue to be used in Germany after the war as substitutes for foreign metals. Yet regard should be had to the requirements of the instrument-making industry, which before the war worked largely for export, and should therefore be placed in a position to compete effectively with the instrument manufacturers of foreign countries. As the foreign manufacturers will have more copper and brass at their disposal, the German industry must also have a sufficiency of these metals, lest the German product should come to be regarded in the world market as of inferior quality. Even to-day it is not always possible to use substitute metals in the manufacture of instruments. This applies in particular to such as are subject to weather conditions (e.g., nautical and measuring instruments).

In the electro-technical industry conducting-wires of iron and zinc, insulated by artificial silk, or by paper saturated in insulation lacquer, are now employed. —Board of Trade Journal.

WHAT OUR READERS THINK AND DO

Views and Opinions Regarding Industrial Developments, Factory Administration and Allied Topics Relating to Engineering Activity

MACHINE FOR ACCURATELY CENTERING SHELLS

ONE of the most difficult operations in connection with the machining of shells has frequently been the cleaning out of the inside profile after the closing of the nose. While extreme accuracy of this particular section is not absolutely essential it is very important that the surface be made smooth and free from prominent ridges or chatter marks, and conform closely to the contour of the bore. Owing to the small opening at the nose after the bottling operation it has often been a problem to provide tools of sufficient rigidity to meet the requirements of this machining detail. In many cases special devices have been designed for this work, but the general practice is the adoption of a boring bar of such a shape as will give the greatest strength for the work required. To do this it is necessary that the bar be released from the turret before it can be placed in or removed from the shell. It has been found advisable, therefore, to maintain as uniform a shape to these bars as conditions will permit so that the cutters and bars can be used interchangeably.

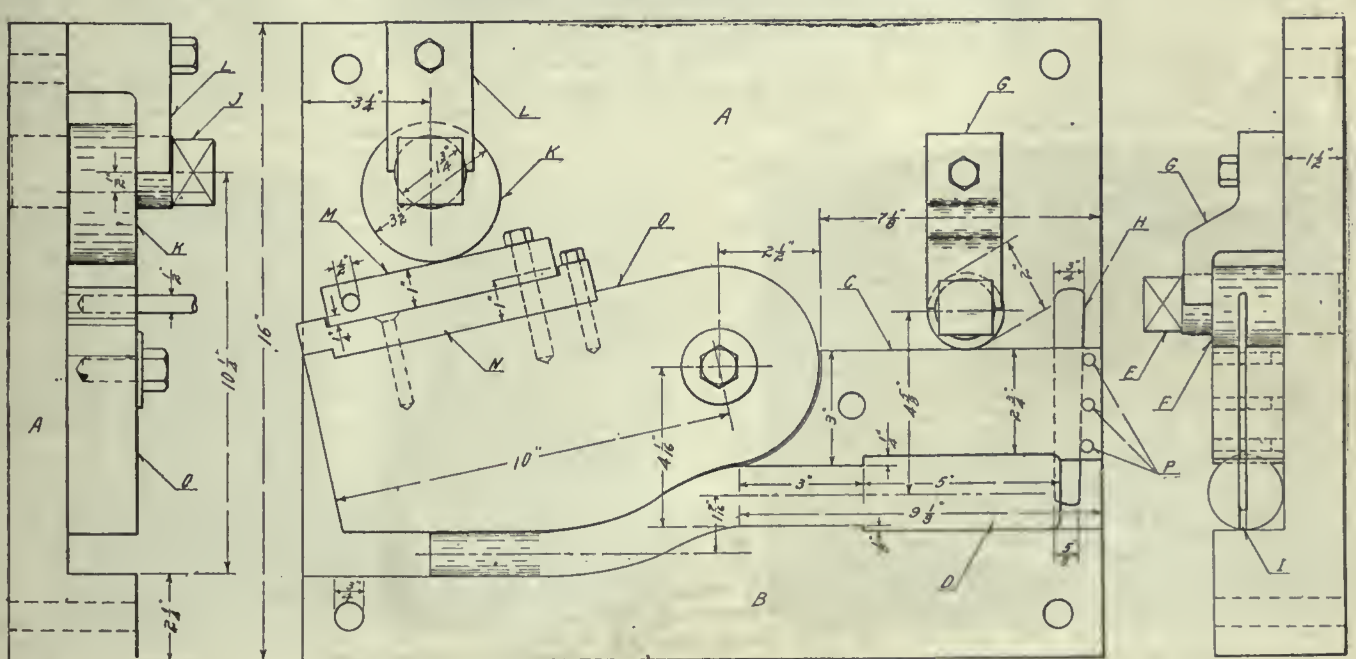
The system adopted at the plant of the Modern Tool Mfg. Co. is to form these bars in a special fixture so that they are virtually identical in every particular. The accompanying sketch illustrates that appliance as now used. The base plate A of the machine is 20 inches long and 16 inches wide, and along one side is the form block B, cast integral with the base. The cylindrical portion of the bar that fits into the hole in the turret is gripped firmly by the clamp C. This clamp is operated by using a wrench on the square E, this square forming the upper portion of an eccentric bolt F, the lower pivot of which fits into a hole in the plate and the upper end supported by the thrust piece G. The lateral position of the bar in the fixture is determined by the wedge H that passes through a slot in the piece C, the tail end fitting into a slot in the rear of the boring bar. This slot has a relative position to the front section of the bar and assures a uniform shape to the latter after bending. The thrust of the wedge is taken by the three pins D.

When the small end of the bar has been turned to the desired shape and size, it is placed in the fixture and bent by the action of the forming block O. This is accomplished by the turning of the eccentric bolt K, this bolt being supported in a similar manner to the one for clamping the large end. Owing to the distance through which the bar has to be bent, it is necessary to perform the operation in two movements. That is, the bar is first bent part way by revolving the eccentric on the block N. When the limit of the eccentric is reached on this block the upper block M is swung into position and the operation is completed. This appliance has given very satisfactory results.

DRIVERS FOR SIMPLE CYLINDRICAL WORK

By Howard W. Dunbar.

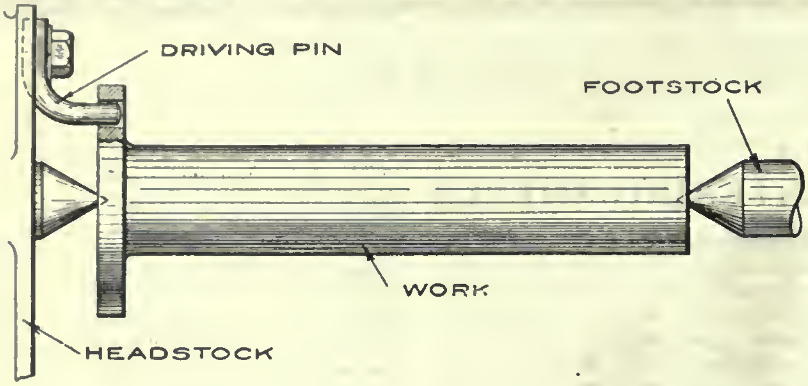
Much of the time consumed in grinding may be chargeable to the handling of the work, the loading and unloading of machine, and provision for clamping the driving means to the piece to be ground. We illustrate this month two simple driving arrangements which readily engage themselves with the work to be ground. They are only applicable to work which has drilled holes in the

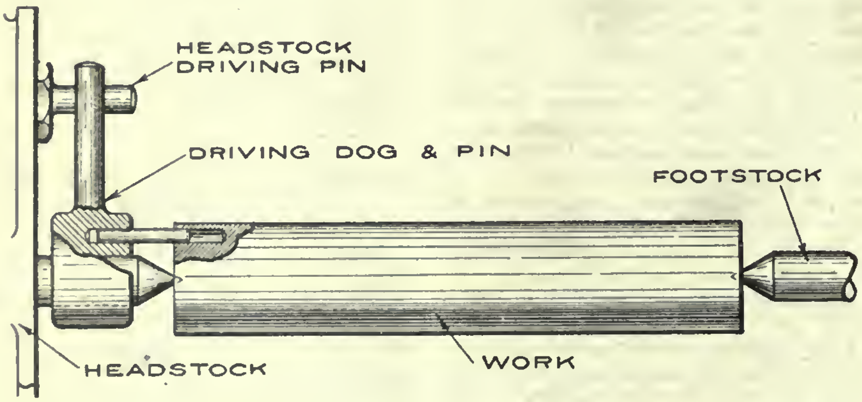


end, which in turn can engage the driving pin, such as a flange shaft with holes drilled in the flange, or pieces in which a hole has been drilled to provide for this driving means.

In one illustration the driver is a loose bushing which fits the centre of the machine and revolves freely about this centre when in engagement with the driving pin on the face plate, and which in turn carries a driving projection that engages the hole in the piece of ground work.

The other illustration is a simpler device which is fastened to the face plate and revolved as a direct engagement with the hole in the piece to be revolved. Both of these features have their advantages, and should be applied depending on the conditions surrounding the grinding operation and the ease with which they fit themselves to each individual case.—*Grits and Grinds.*





THE INTELLIGENT CHECKING OF DRAWINGS

By ROBERT MAWSON

IN the present day rush to get out war supplies, there is a scarcity of designers and draftsmen as well as other branches of engineering industry. This condition has changed very materially the routine of drafting offices.

Before the war the customary practice in most drawing offices was to advance the men according to ability and length of service, from the board to checker, assistant chief draftsman and eventually to chief draftsman. By this process a man gradually becomes accustomed to office conditions and practice, and when he was given the position as checker he was in a fair way to handle it successfully.

Taking the case of the special small tool industry, however, in these war supply manufacturing days the old regime does not hold good. Tool designers are moving from office to office and many of them are given the position of checker who never did the work before. To many people this duty seems the easiest work of all. To them it is simply a case of checking up dimensions carefully or otherwise, as you feel like it, and trusting to the accuracy of the tool designer.

I said in passing, "If you could or had an opportunity to do that work you might find it a rather serious joke."

To the checker belongs largely the success, or otherwise, of the work turned out from an engineering department. With this in mind I have tabulated the chief points which I found most important to be observed when acting as a checker on toool designs.

1. Check if the part to be machined is laid out correctly to scale and see if there is sufficient clearance between it and wall of the tool to avoid interference.

2. See if the surfaces to be machined on the tool are the best design to suit the equipment of the shop.

3. Check dimensions of tool, see if walls are strong enough and not too thick to make the tool awkward to handle.

4. Check if straps and other fastenings are strong enough and are so arranged that the piece being machined may be removed conveniently, also see the nuts, if the tool has any, can be tightened without using special wrenches.

5. See that there is sufficient chip room on jigs, boring fixture and the like, so the chips do not either clog the tool or interfere with the correct locating of the piece in the tool.

6. Check if the tongues on milling fixtures are correct to fit milling machines, splining machine or machine tools when the tool is located by means of tongues.

7. On punch press tools see that the machine has sufficient stroke to suit the design.

8. Check title for correctness of scale, names of designer, tracer, number of drawing dated, also note to have tool stamped. It will be observed that I take up first the checking of the correctness of the piece's layout.

If this has been laid out to the wrong scale the usual consequence is that the tool will be also wrong and interference will occur—see the designer starts out right.

The second point is also important, as often a slight change in design to avoid expensive tooling or sometimes special set-ups will change very materially the cost of making jig or fixture.

As regards the third point, often jigs are designed with the walls so thick and the tool so heavy that it requires two men to handle it.

This can be avoided by coring out walls and ribbing the casting to get the required strength and yet reduce the weight very materially. Checking up fastenings is important as the ease by which those can be manipulated determines the value of the tool as a time saver.

If a case should arise where a special wrench is necessary, see that it is designed and stamped with the number of the tool, kept with it in a box or other means in the tool crib, so that it is at hand when required.

The fifth point needs no comment, as any one acquainted with the use of special tools realizes the value of chip clearance.

As regards the seventh point, if a punch press tool has been designed for a press and it be found that the machine has not sufficient stroke either re-design the tool if feasible, or change it to suit a press having the required length of stroke.

The eighth point is obvious, but it might be added, see that the note calling for the stamping of the tool is plain and unmistakable, if need be underline it.

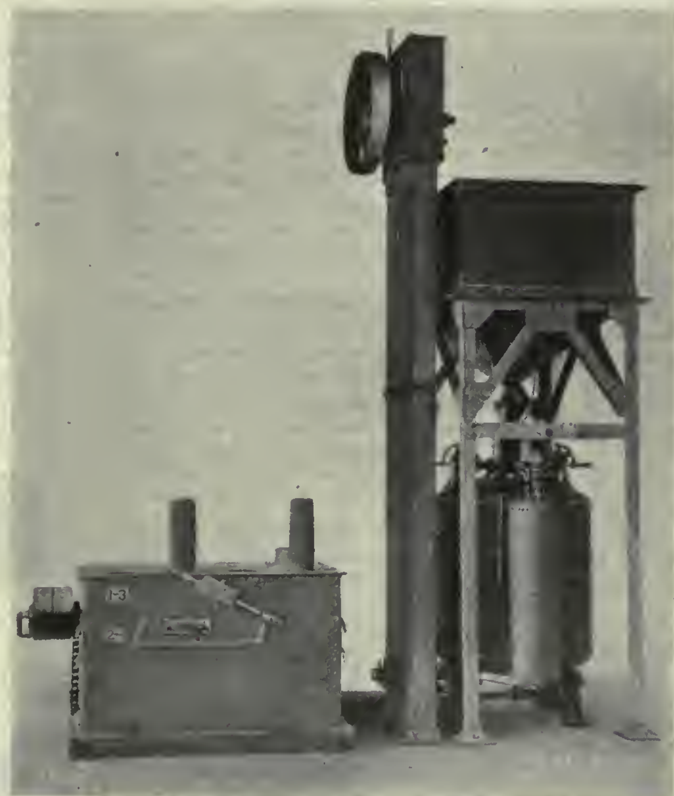
I trust these ideas which I have found useful will also prove valuable to the reader, enabling corners to be cut in checking, back stepping and yet cover the matter so the tool can be sent out into the tool room, knowing that it will be built to do the work successfully and yet the checker feeling he has not slipped on his work.—Robert Mawson, Hamilton, Ohio.

DEVELOPMENTS IN SHOP EQUIPMENT

Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.

AUTOMATIC SHELL CLEANING CABINET SAND-BLAST

This machine is designed to provide continuous operation for cleaning 155 mm. shells with direct high pressure. Primarily it consists of a cabinet in which are mounted four rotating chucks driven at slow speed on dust proof ball bearings. The chucks are driven by a belt from a main drive gear at the rear of the cabinet, and alternate chucks revolve in opposite directions. All driving gears and mechanism are contained in a separate dust tight compartment. A direct high pressure sandblast machine supplies two lines of hose feed, two nozzles which are positioned to project within the nose openings of alternate shells. The shells are placed in the rotating chucks opening downward, and as the two alternate shells are cleaned, the nozzles are thrown by a lever on the front of the cabinet to the other shells without stopping the blast action while the clean shells are removed and others placed in the chucks for cleaning.

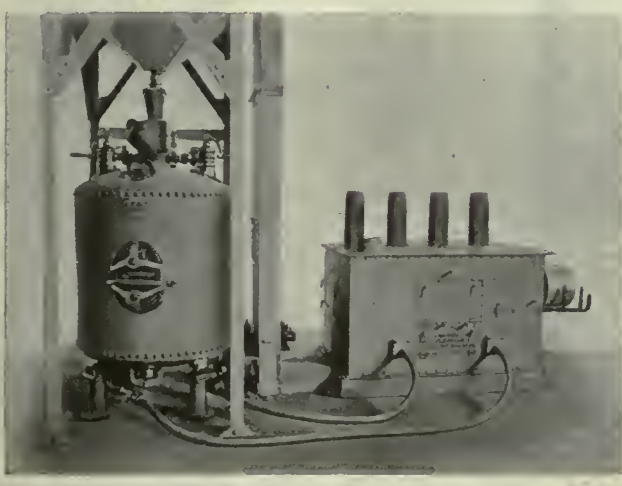


SAND BLAST MACHINE FOR SHELL CLEANING

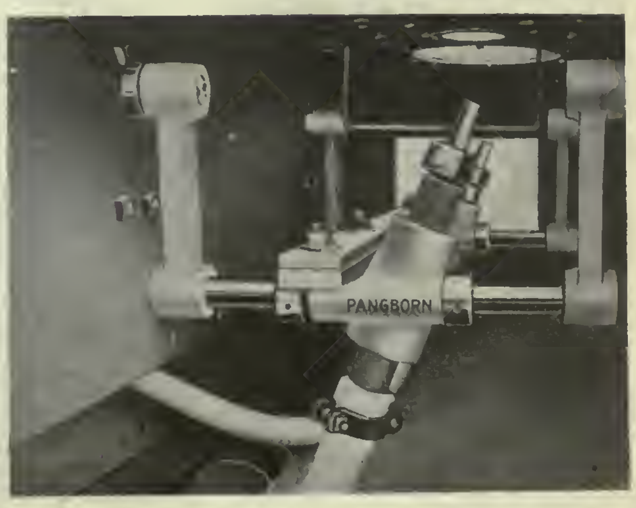
A hopper formed in the bottom of the cabinet receives the spent abrasive which is conveyed to an elevator and rais- to an abrasive separator over the sand-blast machine, which by mechanically operated screens and strong exhaust, at one operation removes both fine and coarse material which passes to a refuse bin, the clean, sharp abrasive for refuse being delivered to a storage bin for refilling the sand-blast machine.

The shells are simply placed in the chucks, which are so designed as to firmly hold the shells in position without other support or attachment, which leaves the top of the cabinet entirely free for manipulation and observation of the shells.

The sand-blast machine can be used with either sand or the metal abrasives, and the equipment in actual practice is cleaning 90 155 mm. shells per hour. The cabinet is also made for other size shells. The illustrations attached show the detail of the chucks and the driving belt, two of the chucks being removed and the nozzles seen through the openings. The lower illustra-

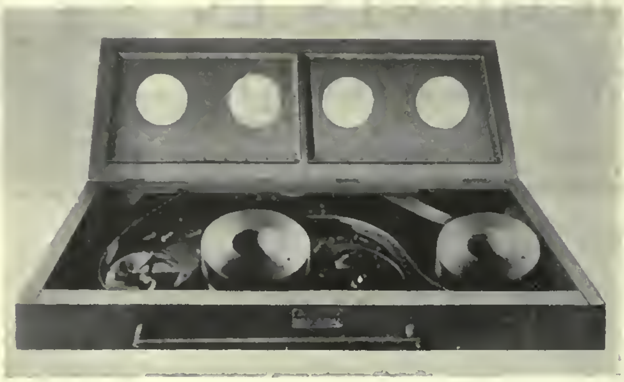


REAR VIEW OF MACHINE



DETAIL OF SAND BLAST NOZZLES

tion shows the hose connection to the nozzles and their method of movement by the lever handle on the front of the cabinet, and a section of the



conveyor can also be seen in the bottom of the separator. This machine is manufactured by the Pangborn Corporation, Hagerston, Md.

RADIAL DRILLING MACHINE

A wall radial drilling machine, as made by the Lynd Farquhar Co. of Boston, Mass., is described and illustrated herewith. This is a well designed and carefully built machine, and special care has been given to locate the entire control of the machine within easy reach of the operator.

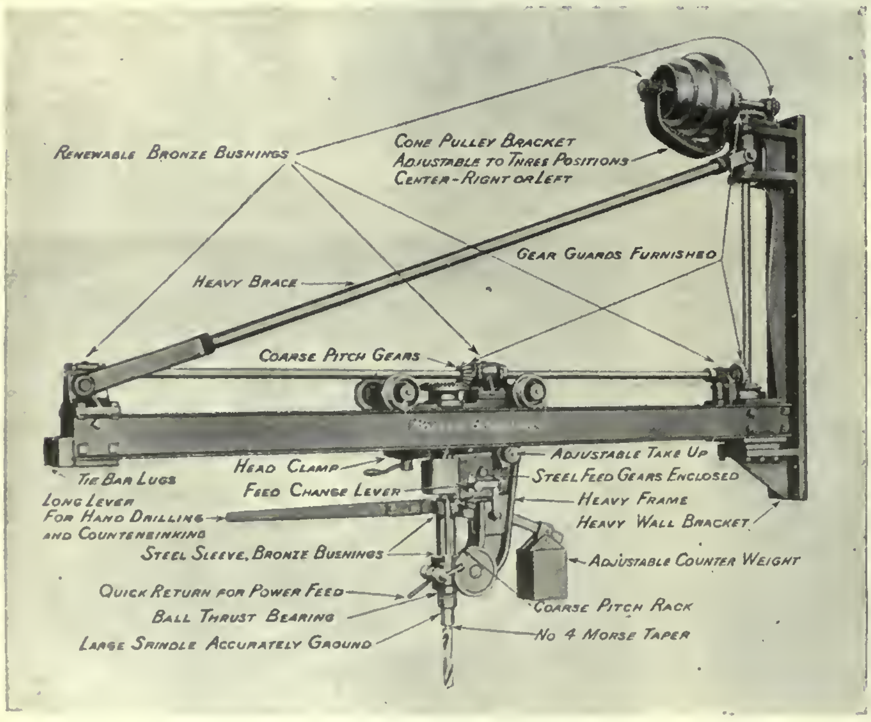
The arm is constructed of extra heavy channels, accurately planed top and bottom, with substantial supporters at each end, and is supported from outer end to top of wall bracket by heavy steel brace bars.

The wall bracket is heavily ribbed, planed on back and where bolted to the wall is 10 in. wide, 6 ft. 10½ in. high. Bracket at top of machine with bevel gear housing can be located at three positions for convenience in connecting belt drive from countershaft.

The motor application is made by mounting 5 to 7½ H.P. variable speed motor on suitable brackets, which will be furnished at extra cost, in place of bracket that carries bevel gear housings.

The head is exceedingly rigid, mounted on four flanged wheels fitted with roller bearings, and moves with extreme ease from end to end of arm. All gears are accurately cut from the solid, feed gears being of steel. The bearings are bronze bushed and renewable. The wheels, carrying heads, are fitted with high grade roller bearings.

A hand lever feed, nicely counterbalanced by adjustable weight for light drilling and countersinking, can be adjusted to remain in any position. The geared power feed has two changes, .015



WALL, RADIAL DRILLING MACHINE

to .025 per revolution of the spindle. Can be changed while drill is in operation, and provides a good range of feed for drills up to 2½ in. diameter. An automatic release of power feeds to spindle is provided at extreme traverse of spindle to prevent damage to feed gears.

The spindle is of high carbon steel, 2½ in. diameter in bearings, is accurately ground, runs in long bronze bushings, (renewable) within a steel sleeve; has 7 in. traverse; No. 4 Morse taper hole, is fitted with high grade heavy duty ball thrust bearing. Upper end of spindle 2⅜ in. dia., and slides through heavy steel driving sleeve to which is keyed the main driving gear.

An adjustable eccentric wheel on under side of arm keeps the carriage in proper adjustment along the channels.

A clamp lever conveniently located, clamps head rigidly to the arm. Tie bar lugs are provided at extreme end of arm to receive tie bar in event it should be found desirable in extra heavy drilling. The countershaft is self oiling, tight and loose pulleys 16 in. diameter, 4½ in. face, and should run 350 R.P.M.

DIRECT CURRENT FACE LATHE.

MOTOR HEAD FACE LATHE

In developing the face lathe shown herewith, the Oliver Machinery Co., Grand Rapids, Mich., have kept in mind the desirability of having a machine tool which would be entirely self contained. The motor head, the controller or switch and the rests are mounted on the floor column, making the machine especially desirable as a portable face lathe. All the electrical parts are totally enclosed—dust proof.

The lathe swings 24 inches over bracket, 20 inches over rest socket and will turn work up to 12 inches wide by 20 inches diameter or 6 inches wide by 24 inches diameter. Great care should be taken not to run these lathes at a higher speed than the work at hand will warrant.

The spindle is made of steel tubing selected for strength and durability. It

REAR VIEW OF ALTERNATING CURRENT FACE LATHE

is 1¼ inch diameter and has a ½-inch hole its entire length to facilitate removal of centers. The inside end is threaded for face plates and bored to receive No. 2 Morse Taper Shanks. Outside end carries a hand wheel for holding the spindle for removing face plates, for turning spindle by hand when making adjustments, or for quickly stopping motor. When rear end turning is desired, the hand wheel may be replaced by a face plate.

Either a. c. or d. c. motors may be fitted to the head according to the available supply.

The a. c. motor head will run at 800 to 3,500 R. P. M. The d. c. motor head will operate at 600 to 3,000 R. P. M. The a. c. motor is of the single phase, series-compensated type, and will operate on any single or polyphase circuit of the proper voltage and also on any frequency from 25 to 60 cycles. The wiring from main line to motor comprises two wires only, making its connection simple through the avoidance of a multiplicity of wires incidental to the use of regulators or rheostats. The lubrication is very simple and confined to the occasional filling of grease cups.

The stator frame is constructed of laminated steel reinforced with iron spacings blocks inserted to absorb the thrust, which insures absolute rigidity of the headstock. Speeds from 800 to 3,500 R. P. M. or any intermediate speed may be obtained by simply turning one or the other of the conveniently placed hand wheels. There are no feed rheostats, regulators or relays, the entire controlling mechanism being contained in the motor.

The d. c. motor has a frame made of soft cast steel and which fully encloses all current carrying parts. The upper cover on the commutator end is for inspecting brushes. Polepieces are drop forgings of very high magnetic permeability. Field coils are form wound and thoroughly insulated. Bearings are ring oiling and adjustable for wear. Commutator bars are made of hard drawn copper, insulated from the commutator center and from each other by selected mica. Commutator uses two brushes per stub, eliminating brush trouble and sparking. Armature is mounted on a special shaft constituting the head stock spindle. The core is built up of laminations of soft steel sheet heavily insulated before the coils are wound into place.

FACE LATHE FOR USE ON ALTERNATING CURRENT.

RETURNED SOLDIERS ARE NOT MUCH IN FAVOR OF FARM LIFE

WE spent many an evening in France in our little mess, discussing the problem of what the men would want to do when the yreturned, and how they would be absorbed into the life of the community. From what we had seen we came to the conclusion that many of the men who had been working in clerical positions in cities, now that they had had a taste of life in the open, and had become rugged, would go to the farm in preference to the city. But we have had to reverse that conclusion. We now find that the men, even those who had come from the land, will not go back to the farm when they come home, because, for one reason, they have become more or less gregarious; they have lived together, and men who had lived a lonely life before have now had friendships for years. They have made strong friendships, and they have come to a different point of view on almost everything.

The returned soldier is a man who cares very little for wealth or for position; he will look you right in the eye and tell you exactly what he thinks. I have had men applying for positions who have been private soldiers, and, although I was in uniform, they would come in and talk to me in a way they would not have dared to do had they been in uniform. They have seen things and they realize a good deal of what is real in life. When we talk of the returned soldier we must consider, first of all, his mental point of view. The returned soldiers, particularly those who have been in the field for more than two years, have been and will be to a large extent spoiled for ordinary work. Many things they considered worth while before will no longer attract them. They consider, for instance, that the question of making money is not the greatest thing.

The system under which the wounded man lives, and is encouraged to do nothing, in the hospital, really trains him to be a loafer. He is deliberately trained to do nothing. The first thing to do with the average man when he comes back is to get him gradually broken in to the idea of working and becoming a citizen of the community. I know myself—I came back sick, and I can speak from personal experience—that it has taken me practically to the present time to get the point of view of the civilian that things here are worth while. The man at the front has passed through great experiences, and, when he comes back, the ordinary things of life seem dull and unprofitable. In some way he has to get out of that attitude, which is largely mental.

Economic conditions after the war will play a large part in the absorption of the returned soldiers. Whether competition be great or not, I do not think these men will go on the land unless some means can be provided whereby they can live together and have a community life. I do not think they will consider for one moment going back on those large farms on the prairies.—Col. George C. Nasmith, M.D.

It is not being out at heels that makes a man discontented, it is being out at heart.—Bliss Carman.

The best compensation for doing things is the ability to do more.—Ginger.

Any man is a success who can do his work without supervision.—Elbert Hubbard.

Too low they build who build beneath the stars.—Dr. Young.

A wise man is never less alone than when he is alone.—Swift.

A negative thought is a poison as deadly as arsenic.—H. L. Fogleman.

He who does not advance recedes.—Latin.

I have often wanted Fortune, but oftener Enterprise.—Montaigne.

When you begin to feel sorry for yourself, you have a right to be.—Logging.

Nothing is impossible to industry.—Periander of Corinth.

Success will go a block out of its way to dodge a lazy man.—Sun.

A Poor Place to Work

HOW is it that municipalities can continue to secure the assistance they require in the way of competent officials? There are two forms of employment that are not desirable. One of these is appointment under political patronage. The other is a position in the gift of a civic governing body. In some cases a mistaken individual may be inclined to regard either of these as sinecures. They have a mental picture of short hours, pleasant offices and easy work. Unfortunately in some political appointments these specifications have been lived up to.

But the average civic official has not a desirable appointment. In Toronto this week we have had the spectacle of the Mayor telling the Medical Officer of Health that he ought to apologize for drawing his salary. Salary increases were threshed out, and the petty raises doled out in many cases were made the cause of prolonged discussions, all of which appeared in print. A man with a good sized backbone stuck into his system would ten times rather go without the miserable increase than have his salary matters paraded before the public in such cheap fashion.

There is many a well-trained official serving in the capacity of city engineer to-day who is simply going to seed because he knows that his official head would come off close to the collar-bone were he to get up and speak the blunt truth about the manner in which civic affairs are carried on.

Pity the man who gets jockeyed into the position where he can't call his soul his own, and where his best accomplishments are simply a second rate performance of the best that is really in him.

Public and Private Methods

WHY is it that government institutions seem so often to lack in the fine precision of detail that makes private operations in the same line a success?

For instance, right now such a condition exists at Vancouver. In the Vancouver *World* of recent date the following appears:—

"Vessels are unloaded, re-loaded and get away from Vancouver just as quickly as anywhere on the Pacific Coast.

That is, some vessels are.

When a C. P. R. boat comes in she finds one empty shed to receive her freight and another full shed to be emptied into her hold. Loading is going on at one end of the ship and unloading at the other.

Also the freight does not accumulate in the shed. There are cars, all the cars needed, to take it away and so prevent congestion. Also switching engines to move the cars.

And likewise at the Great Northern dock.

But not so, not by any means so, at the other docks and at the government dock in particular. There the freight piles up and piles up in great mountains so that it takes a gang nearly twice as big to work a hatch as the gang working a hatch in a C. P. R. steamer.

And moreover, if C. P. R. or Great Northern boats are in the longshoremen find it better to go to them than go out to the government dock, where they are a long way from home and not a solitary restaurant is working at night when a man wants some hot coffee to see him through.

Now that condition is too often indicative of the difference between public and private ownership. The private company has to study actual competitive conditions and meet them. The government can afford to take the position too often of knowing that a deficit is not going to wreck their business. The Vancouver case looks like one that will stand some explanation.

The Viewpoint of Two Men

SOME months ago it was brought to the attention of the Kaiser that one mother had lost nine sons in the war. The German emperor thereupon wrote to her as follows:—

Nineteen-Eighteen

Frau Meter;—

"His Majesty the Kaiser hears that you have sacrificed nine sons in defense of the Fatherland in the present war. His Majesty is immensely gratified at the fact, and in recognition is pleased to send you his photograph, with frame and autograph signature."

What sympathy! What comfort to that heart-broken soul who had sacrificed nine sons while the Kaiser's six, resplendent in all the official trappings of war, are as safe to-day as they were on the first day of the conflict!

The wording of the message is hardly short of blasphemy. Viewing the loss of nine sons with smug complacency the beast of Berlin expresses his gratification!

Abraham Lincoln had occasion to write at the close of the Civil War to a mother who had lost five sons in battle. His letter ran as follows:—

Executive Mansion, Washington, November 21, 1864

Mrs. Bixby, Boston, Massachusetts.

"Dear Madam: I have been shown in the files of the War Department a statement of the Adjutant-General of Massachusetts that you are the mother of five sons who have died gloriously on the field of battle. I feel how weak and fruitless must be any words of mine which should attempt to beguile you from the grief of a loss so overwhelming. But I can not refrain from tendering to you the consolation that may be found in the thanks of the Republic they died to save. I pray that our Heavenly Father may assuage the anguish of your bereavement and leave you only the cherished memory of the loved and lost, and the solemn pride that must be yours to have laid so costly a sacrifice upon the altar of freedom."

Yours very sincerely and respectfully.

A. Lincoln.

There's something in that message of Lincoln's that appeals to the manly man and the womanly woman. There's a depth of feeling and a wealth of heart-felt sympathy that speaks the innermost convictions of a godly man.

There is enough in those two letters to show why United States is with the Allied forces in the greatest war the world has ever seen.

OUR idea of an accomplished man is the chap who can ride in some other person's motor car with that splendid indifference that makes the real owner look like his chauffeur.

* * *

If you're making twice as much money as you used to, don't forget to peel off a ten spot and slide it into your hip pocket occasionally.

THERE'S ALWAYS A WAY UP FOR THE MAN PREPARED

Technical Education With Practical Experience Make a Winning Combination

By A. J. T.

CERTAIN learned books lament that talking as an accomplishment is a lost art. So it is. For in the more practical environment of its new abode—industry—it does not aspire to be termed an art. Nevertheless, one commissioned to find it in a hurry would not search first in the production end of business. But there, and just yesterday evening, this ability to talk interestingly, pleasingly, was found in the person of William C. Beck, superintendent of the Consolidated Optical Company, of Toronto.

"Thirty years ago," said Mr. Beck, "I was 15 at the time and I am about 45 now, so it would be 30 years ago—I did my first work for the Ball Electric Light Company, Adelaide Street, Toronto.

Wm. C. Beck

"The following five years I'll pass up, if I may; for I'm sure I did not greatly help the several firms I worked for, and I'm just as certain that they did not help me.

"Twenty-one years old, with the machinery of a ramshackle brick yard in my care, I rubbed shoulders with dissatisfaction. What was there ahead for me? In school I had not gone beyond the third book. A married man without a trade, without education enough for an office stool, what was there that I could do?

"I left the brick yard and for a time favored the Toronto Electric Motor Company, making rheostats mostly. My wage was to be six dollars weekly. Sometimes it was. But all too frequently one dollar or a single fifty-cent piece was all I obtained for six days' labor. Consequently, if dissatisfaction had been shoulder-high before, here both fists of the old Goader pummeled me.

"To understand my plight you should know what times were like 25 years ago. It was a trying period of industrial stagnation. Men begged for work—and did not get it. Why, even journeymen machinists—the best of them—took their twelve per with a prayer of thanksgiving.

"Groping for a way out, I met Walter Inglehart, then in charge of McFaren Dental Supplies and now, by the way, superintendent of a large Chicago plant. Under Inglehart I made my own patterns and forgings. But this work was heart-breaking, for I knew so little and willed to do so much.

"It was through Inglehart that I started attending the 'Tech.' Three nights a week I went until I had mastered algebra, elementary electricity, steam, machine drawing and machine construction. So at last I was making headway, if not a fortune.

And not long after more money offered; a dollar and fifty cents a week more, with another advantage: The Ballard Electric Machine Company did the finest class of machine work in Toronto. Here I learned to do real good die and tool work.

"Later Wythe & Carter—their plant was the basement of the old Truth Building on Adelaide, almost opposite Sheppard—offered three dollars and fifty cents more. I accepted.

"One day in this plant the superintendent and a man named Bowker came over to where I was picking tools out of snow banked on the work bench below the street windows. Could I make dies for the gentleman? I could.

"Now this man Bowker managed the Ajax Optical Company and had been superintendent of the Standard Optical Company, a United States corporation with which the Ajax was affiliated. He came often with work, always direct to me, and at length intimated that my future with him might be bright. Finally, more money was proffered. Pay for holidays! I can relish the thought to this day.

"I had just nicely got the run of the Ajax plant when I saw a way to cut out expensive machines then in use. The tool I made eliminated these machines entirely. Other ideas of mine were adopted. And when officials of the Standard Optical Company visited our plant, Mr. Bowker gave me all credit for improvements made.

"Moreover, when the Ajax Company merged into Cohen Brothers, manufacturing opticians, all the Ajax workmen except Mr. Bowker and myself were laid off. He agreed to go with Cohen Brothers as mechanical adviser provided he could have me as assistant..

"Well do I remember the amazement of the workmen in Cohen Brothers' plant the first time they saw me sinking cold steel. 'Bill Beck' there and then acquired a spot in the sun. And I think the foreman, sooner than I, sensed what was to follow. Anyway, when I was made foreman, he took the change graciously enough.

"One week-end, a few months later, I was called into Mr. Cohen's office. This was my first personal contact with any one of the three Cohen brothers. I was somewhat nervous but not long being left in doubt. For Mr. Cohen, commending my work, evinced an interest in my future amounting to this: A small holding of stock in the company and a wage increase, part of which would go to pay for the stock. I'd have to pay interest on shares I held, but this was more than offset by the fifteen per cent. dividend this stock was then earning. Further, in the event of my death, it was stipulated that this stock would be turned over to my wife as fully paid up. So you see, from every angle, the proposition was most generous.

"That week-end Mrs. Beck and I talked it over, and of the one possible objection our happy anticipations made light. I refer to Cohen Brothers' superintendent. He was not liked. And although I continued to get along fairly well with him, Mr. Bowker would not and, in consequence, he returned to the Standard Optical Company.

"In time there was talk of another merger and intimations that I stood a chance for the superintendency of the then forming Consolidated Optical Company reached my ears indirectly. The intermediator—a friend of mine—said I was the man for the job. I also thought so and said so, provided I could have a free hand.

"But I was merely 'Bill Beck in the jeans' to our present managing director. Therefore, although he slated me for superintendent, I believe he did the trick with no small amount of skepticism.

"That was ten or eleven years ago. Much has happened since. One thing I'll mention, because it shows the far-reaching effect of my having been prepared when Bowker wanted those dies. The Standard Optical Company offered me over a thousand dollars more than my salary at the time to go into their plant as assistant superintendent, with the position of superintendent an assured thing shortly.

"Respecting salary, however, as it grows I'm afraid a man loses the sense of proportion. Mine increased a round thousand a few months ago. I took it as a matter of course. So I suppose," Mr. Beck smiled in conclusion, "never again shall I thrill to a prospect as I thrilled to Bowker's promised pay for holidays!"

Gladstone's grandson wrote his mother on March 23, 1915, the first day he was at the front: "The length of life which a man lives does not matter so much as what he is able to accomplish in that life."

MARKET DEVELOPMENTS

Tool Trade Receives Impetus by U.S. Buying

U.S. Government Places Orders For Much Equipment For Various Plants—Spanish Influenza Serious Factor in Decreasing Work Production—No Relief in Sight For Steel Plate Situation

PROMISES of relief in the shortage of steel plate and light sheets have shown no signs of materializing as yet. Some of the warehouses have no stock on hand. The War Board continues to cut close on the orders that it allows to pass for filling and in some instances a disposition has been shown to release material for repairs more readily than for new work.

Manufacturing interests in Canada and the United States are being hard hit in many cases with Spanish influenza.

It is reported that plants in the Chester and Eddystone district, Philadelphia, including the Baldwin Locomotive Works, are short 50 per cent. of their workmen. One plate mill's production dropped to one-third last week; it had been operating at over 95 per cent. Some others show a reduction of 25 per cent. in workmen. The Hog Island ship plant is short about 10 to 15 per cent. of workmen. It is reported that Worth Bros. Co., at Clayton, Dela., will close down temporarily. There are said to be 200,000 cases of influenza in Philadelphia, and strict measures are being taken to fight the epidemic. Office forces are badly depleted and much work is being held up. Plate mills are also watching their pig iron and coal supplies closely. The mills buying these materials are using them from hand to mouth and are unable to accumulate stocks for the winter.

Industrial centres in Canada report much the same condition of affairs.

There has been considerable activity in the buying of machinery last week. In the East some large orders were placed in the Philadelphia market, but New York and New England trade was relatively quiet. The United States government dominated the trade in all sections, the Ordnance Bureau of War Department placing orders for tools for arsenals and also buying for manufacture, with whom it has placed contracts for guns, shells, and aircraft. Large contracts are still pending for equipment for gun shops at home and abroad.

Recent activity throughout the industry is reflected in an advance of prices for some lines of tools.

The War Department has approved appropriations calling for the expenditure of several million dollars for additions to arsenals and for several other plants that are executing gun and ammunition contracts.

The scrap market during the past week has been devoid of any changes of interest. Only a fair amount of business is coming in. The orders are smaller than usual, and apparently users in many cases are not inclined to stock up. American points have been reporting a very serious shortage in all grades of scrap, but within the last few days it has come to notice that some of the dealers there are actually in the market with very attractive tonnages of sorted material for sale. Canadian dealers have been contending all along that access to the U. S. market would be a good thing for them, but the embargo has prevented this. It would seem now that selling in the home market, although more limited, is about their only chance.

STEEL PRODUCTION VERY MUCH IN ADVANCE OF ESTIMATES

Special to CANADIAN MACHINERY.

PITTSBURGH, Pa., Oct. 16.—The rate of steel production in September was 12 per cent. above the rate in August, which was about 4 per cent. below the rate in four months preceding. The increase even exceeds the expectations that were entertained, based on tre passing of hot weather.

A further and very encouraging fact has come out, by reason of the practical completion of statistics of the country's steel ingot production in 1917. Previously information as to ingot production has come through reports of 29 large companies, which reported monthly. In 1916 these companies made 88.15 per cent. of the country's output, and it has been assumed, naturally, that they contributed about the same amount to the 1917 output. On that basis the 1917 output was about 42,200,000 gross tons of ingots. Now, however, returns from practically all producers for 1917 show that in that year the output was about 43,700,000 tons, or 1,500,000 tons more than has been assumed. The 29 companies contributed only 85.10 per cent. to the 1917 output, presumably by the fortuitous circumstance of other producers having indulged in more new construction than did the 29 companies as a whole.

On the basis that the output of the 29 companies in September represented 85.10 per cent. of the total output, as was the case in 1917, and making allowance for the number of working days, the country produced steel ingots in September at the remarkable rate of 46,800,000 gross tons a year. The favorite estimate of capacity has been not less than about 47,000,000 tons, this estimate being based on actual output in 1916, which was 41,400,000 tons, plus allowance for new construction. Outputs have appeared to fall much below this amount, and the forced explanation has been that on account of war time difficulties, largely the shortage of scrap of good quality, the output feasible under normal working conditions could not be obtained. Now the situation appears much more favorable, and the common view is that October will show a better rate of production even than September. Naturally there will be some decrease with winter weather, but perhaps nothing serious.

Steel Requirements and Supplies

These new steel ingot production statistics permit a close examination of steel supplies in relation to requirements as formulated by the War Industries Board and an estimate of the deficit between supplies and the program, with enquiry as to where the deficit will fall.

It will be recalled that early in July the War Industries Board estimated the steel requirements for the half year at 20,000,000 tons, this being in net tons of finished rolled steel. At the same time it pointed out that the industry had never made more than about 16,500,000 net tons in a half year. There is some doubt whether that statement was strictly correct. Later the board increased its estimate of the requirements to 23,000,000 tons for certain, with a possibility that the total might be 25,000,000 tons. The increases were due, first, to increased demands of the A.E.F. and our Allies, and second, to large demands of the Railway Administration for rails and for cars in addition to the 100,000 bought a few months ago. The board's estimate of supply was increased only to 17,000,000 tons.

There is information available that permits a close estimate of rolled steel supply from the tonnage of ingots produced at about 6,200,000 net tons in July and August, and at about 3,300,000 tons for September, making 9,500,000 tons for the three months. In view of the September rate of output and the expectation that October will do still better, 10,000,000 tons or possibly a trifle more is to be expected for the current quarter, making 19,500,000 to 20,000,000 tons for the half year.

Thus there will be a deficit of not less than 3,000,000 tons between the supply and the estimated requirements, and the question, now that production is speeded to the utmost, is simply where the deficit will fall. Enough is now known to make a rough approximation. It will fall in part upon supplies for the general war program, chiefly by way of reducing the factor of safety that has been used in making up the estimates, and partly upon the commercial industries that have been recognized as helpful in winning the war.

It is certain that some parts of the war program have been allotted more steel than they could currently use, whereby reservoirs have been created against the possibility that speeding up afterwards might draw from these reservoirs Three instances may be mentioned in connection with the prospective reduction in the factor of safety, shell steel, ship steel and railroad steel as follows:

(1) In the past ten days a large shell forging plant at Bridgeport, Conn., has been closed for lack of steel, while a forge shop at Cleveland lost three days' time and is now put on the basis of operating two-thirds capacity. The supplies of forged material have been well in excess of the capacity of the machine shops to make finished shells, and thus the production of shells will continue as formerly, but the reservoir against speeding up of machine shops in future is decreased.

(2) The quota of plates for shipbuilding has been 50,000 net tons weekly for several months past. Several weeks ago a survey showed that fully 1,000,000 tons more plates had been shipped from mills than had been applied to steel hulls. Likewise, there have been many more steel hulls launched than have been completed, because the bottle neck has been the flow of engines, boilers and the thousand and one other appurtenances needed for completing hulls. As the flow of equipment is expected to increase greatly, and as the shipways are certain to launch hulls more and more rapidly each month, it was desirable to have this factor of safety, of hulls awaiting completion, and of plates awaiting application in hulls. Two months ago the Director General of Shipbuilding desired that the plate allotment be increased from 50,000 to 70,000 tons a month, but this could not be done, and there is no likelihood of any increase for some time. Thus, with the steel deficit now so well established it will be impossible to maintain these large factors of safety, but the balance of probability still is that hulls will be launched as rapidly as they can be completed.

(3). The Railroad Administration has been desirous for some time past of receiving 60,000 tons of rails a week, 40,000 tons a week having been furnished. Also, it desired that the 100,000 cars ordered a few months ago be put through, so that additional orders could be placed. The railroads have been functioning quite satisfactorily through the spring and summer, but to cope with winter conditions needed additional facilities to be on the safe side. Now the case is, as stated plainly in an official statement by Chairman Baruch of the War Industries Board, that the Railroad Administration has renounced claim to some of the steel allotted to it in favor of General Pershing, and there is a possibility, with particularly bad weather, of railroad difficulties this winter

As to steel for commercial purposes on the preference list or accorded the lower degrees of priority as helpful in winning the war, there will be still more serious curtailment than there has been and there may be some rearrangement of priorities and preferences to take cognizance of the new conditions when it is clear the steel supply will not stretch through the preference list, and in the case of some products will not last through the priorities, which come before the general preference list. One item in this direction has already appeared. Oil country goods, chiefly tubular products, distributed through jobbers, have hitherto been given B-4 priority, the same as standard steel pipe, whereas when ordered direct by consumers have been accorded B-2. Now the order is that B-2 is to apply also to oil country goods when distributed through jobbers, and the account is to be kept entirely separate from the regular replacement account of jobbers. As the mills cannot increase their output of tubular goods in general, this will mean that jobbers will receive more oil country goods for distribution and less standard steel pipe and even hitherto their replacements, month by month, have been falling somewhat behind.

POINTS IN WEEK'S MARKETING NOTES

United States government places large orders for machine tools and sanctions private purchases for government work.

Spanish influenza is a serious factor in reducing output of munitions and is affecting all the important centres in Canada and U.S.

The scrap metal market reports little change with ample stock on hand.

Several Canadian firms with ample foundry facilities are considering the advisability of making cast steel shell.

The plate situation shows little change with a number of warehouses entirely out of stock.

TRADE WAITS TO HEAR OF NEW ORDERS

On Their Release Will Depend Greatly The Volume of Business for Next Year

Toronto.—Promises of relief in the matter of steel plate and light sheets have shown no signs of materializing as yet. Some of the warehouses are absolutely out of stock in sheets. The ravages of influenza have tended to go even further toward curtailing trade. In nearly every case the steel, iron and machinery business is hit hard. There are departments with no person around to talk business; there are trucks with no driver to operate them, and there are orders with no person to see that they are filled.

The War Board continues to cut close on the orders that it allows to pass for filling. Last week several forging plants applied for plate for ovens in the heat treating process. The first orders were returned, Ottawa wanting to know if the plates were for repair or new work. Apparently the War Board would release material for repairing a plant now operating, while it would hesitate to give out material for new extensions.

The Machinery Business

Deliveries are much better now than

they have been for some time on machine tools of all sorts. As a matter of fact orders that were placed months ago are beginning to see the light of day now, and it looks as though better production results would soon be secured. In a number of cases deliveries are needed, not only by the governments buying the shells but by the contractors, who need the pay for the shells in order to square accounts for the putting in of the plants and the other equipment. Contractors woh have taken on shell work have had to go into a very high market for the purchase of the necessary equipment, and this has put them under pretty stiff obligations in many cases, with the result that they have had to finance pretty close to the shore against the day when their production returns would become a real asset.

There has been a dropping off in demand of recent weeks, but against this dealers report that there are inquiries coming in for machinery that will be used in factories which are already planning for their peace time trade.

More Big Business?

The machine tool trade is waiting now to see if the big business that has been held up at Washington for some days is going to be released. There are a number of conferences going on at present. Undoubtedly the war news of the past weeks has something to do with the volume of business that the dealers are willing to prepare for. Opinion seems to be pretty well divided on war contracts, some of the trade believing that they should play the thing safe now, while others are certain that the call for munitions is not going to fall off for some time yet. It is expected that it may be well on toward the end of the week before any definite announcement is secured on this particular point. On the outcome will depend to a considerable degree the volume of business that will be passing next year. It will make not much difference on present operations, as they are all under contract.

Cast Steel Shells

Several Canadian firms with good foundry practice and equipment are considering the matter of cast shells, and a large amount of these are likely to be called for. In some cases enquiries are out with building contracts for the erection in a hurry of plants to take care of the work. Some of the foundrymen are certain that this form of shell will have to be used in the future if the programme mapped out for production is to be adhered to. The gas shell can be cast, also anything used for bombing purposes, but the cast shell that will satisfactorily stand up against the shock of being fired from a gun is something that has not been brought out yet. Various suggestions are made for the giving of strength to the cast shell, but many of these are so complex and laborious that any advantage that would be gained from having them cast is largely discounted by the additional operations.

Scrap Market Still Dull

Dealers are quite emphatic in stating that the past week has been barren of features. Only a fair amount of business is coming in. The orders are smaller than usual, and apparently users in many cases are not inclined to stock up. The scrap market is a hard affair to gauge. Right along American points have been reporting a very serious shortage in all grades of scrap, but within the last few days it has come to notice that some of the dealers there are actually in the market with very attractive tonnages of sorted material for sale. Just where it came from is the secret. Canadian dealers have been contending all along that access to the U. S. market would be a good thing for them, but the embargo has prevented this. It would seem now that selling in the home market, although more limited, is about their only chance. If United States yards are full they are not going to take on much scrap from Canada even were the embargo to be lifted entirely.

NEW MUNITIONS PLANTS IN U.S. MAKE CALLS FOR RAW MATERIALS

Some of the biggest industrial concerns in United States have put out bids for bessemer iron, but makers are not taking them up. Business that is highly desirable is going begging. The whole output is in the hands of the government, and direct dealing over the head of Washington has been discouraged to the point of absolute disappearance.

Reports on the iron situation are as follows:

Pittsburg.—For the first time in many weeks it can be said that the makers of iron are giving shipments that keep up with government allocations. Production figures show signs of improving, owing largely to the increased quality of the coke supply. Against this, however, is the drawback that as the quality improves the quality is falling off.

New York.—Production efforts are as great as ever in this district, and the peace talk is not having the effect of lessening the pressure. Many of the biggest producers have refused to book any 1919 business, holding their plants at the disposal of Washington.

Philadelphia.—In nearly every case all the sales here are now made f.o.b. smelters, thus shifting freight and war tax to the consumer. Production figures are increasing and sickness has not yet become a factor in holding up the work.

Cleveland.—Since May nearly two million tons of material have been allocated in this district. There is a very small open market left and little business is done in this way.

Buffalo.—Malleable iron is very scarce and the demand is far in excess of the supply.

Chicago.—The call for material for munitions plants increases rapidly. In many cases firms that recently went into the business of fitting out plants are now in shape to take in the raw material.

U.S. GOVT. SANCTIONS INDUSTRIAL PROJECTS; MACHINE TOOL TRADE AFFECTED

Special to CANADIAN MACHINERY.

NEW YORK, Oct. 12.—There was considerable activity in the buying of machinery last week in the Central West, especially at Detroit, Cleveland and Chicago. In the East some large orders were placed in the Philadelphia market, but New York and New England trade was relatively quiet. The United States government dominated the trade in all sections, the Ordnance Bureau of War Department placing orders for tools for arsenals and also buying for manufacturers with whom it has placed contracts for guns, shells, and aircraft. Large contracts are still pending for equipment for gun shops at home and abroad.

Recent activity throughout the industry is reflected in an advance of prices for some lines of tools in the Eastern territory. Makers of sensitive drills have advanced prices 10 per cent., and one large manufacturer of lathes has advanced prices 10 to 15 per cent., while another manufacturer of high speed drilling machines is asking 15 per cent. advance on new contracts.

The War Department has approved appropriations calling for the expenditure of several million dollars for additions to arsenals at Rock Island, Frankford and Watervliet and for several other plants that are executing gun and ammunition contracts. Improvements at the Frankford arsenal, Philadelphia, will cost $1,000,000, about one half of which will be spent for equipment. A large part of this appropriation will be used in the construction of new departments for making cartridge cases. An appropriation of $833,500 has been made for additions to the Rock Island arsenal, Ill.; a large part of which will be for machinery in three lists that have been issued; one of these lists calls for $200,000 worth of tools. Another appropriation of $500,000 has been made for the building of a phosphorus plant at Fairmount, W. Va., which will be constructed and operated for the government by the American Phosphorus Co., of Philadelphia. Still another appropriation of $250,000 has been made for a tetryl plant at Sentre, Mich., including main plant, magazines, power house and boiler plant for which equipment must be purchased.

The Procurement Division, Ordnance Department, has placed an order for one hundred 36-inch lathes with a Cincinnati manufacturer, and has been gathering information in the same territory preliminary to placing contracts for four thousand 20-inch and twenty 4-inch lathes.

The Ordnance Department is about to place orders for shop equipment to be used in the manufacture of Colt's automatic pistols, the orders having been placed for these small arms with the Savage Arms Corp., Utica., N.Y., and with the Lanston Monotype Machine Co., and the S-S-E Co., of Philadelphia. The War Department has also authorized the construction of additions to the plant of the Hero Manufacturing Co., Philadelphia, for making brass, bronze and aluminum products; extensions to cost about $150,000.

The International Harvester Co. has received a contract for 5,000,000 hand and rifle grenades and another order for 750,000 6-inch shells. Orders for rifle grenades have also been placed with another manufacturer in Chicago and with three plants in Milwaukee, these four plants will turn out 140,000 grenades every day. The A. O. Smith Corp., Milwaukee, has accepted an order for making aerial bombs, while the Standard Manufacturing Co., with plants at Pittsburg and Louisville, has received a contract to finish 155 mm. shells. The Best Foundry, Bedford, Ohio, a subsidiary of the American Stove Co., has taken an order to cast and to machine 150,000 6-inch trench mortar shells of gray iron.

Great strides have been made in the manufacture of Liberty motors by plants in Detroit and nearby territory. Recent orders have increased government aircraft orders at Detroit to over one billion dollars. The Willys-Overland Co. has placed orders for $350,000 worth of tools for manufacture of eight and twelve cylinder Liberty motors.

The Flu Hits the Industrial World Hard

In the Philadelphia District Almost a Quarter of a Million Men Are Laid Aside—Instructions That C.M.A. Are Sending Out Regarding Fighting the Malady

THE manufacturing interests are being hard hit in many cases with Spanish influenza. In many cases it is like the old la grippe; in many others the trouble really comes from pneumonia following the first attack.

The best authorities say there is nothing to take as a direct preventive. The only thing in this direction is to try and keep up the powers of resistance to as high a point as possible. In some cases the victim is taken suddenly. In fact it is on record that cases have terminated fatally in eight hours.

It is interfering with production in many centres. In Philadelphia for instance the conditions are as follows:

The ravages of an epidemic of Spanish influenza, grip and colds constitute a serious factor in works' production. It is reported that plants in the Chester and Eddystone district, including the Baldwin Locomotive Works, are short 50 per cent. of their workmen. One plate mill's production dropped to one-third last week; it had been operating at over 95 per cent. Some others show a reduction of 25 per cent. in workmen. The Hog Island ship plant is short about 10 to 15 per cent. of workmen. It is reported that Worth Bros. Co., at Clayton, Dela., will close down temporarily. There are said to be 200,000 cases of influenza in Philadelphia, and strict measures are being taken to fight the epidemic. Office forces are badly depleted and much work is being held up. Plate mills are also watching their pig iron and coal supplies closely. The mills buying these materials are using them from hand to mouth and are unable to accumulate stocks for the winter.

Industrial centres in Canada report much the same condition of affairs.

What to Do

The Canadian Manufacturers' Association is issuing a circular prepared by Dr. Hastings, medical health officer for Toronto. The circular is as follows:

"Influenza is an acute communicable disease and is contracted by coming in contact with the secretions from the nose, throat and mouth of a person who is ill with the disease. For this reason every effort should be made to avoid such contact. This may be done as follows:

"1. The person who is taken ill must go to bed promptly. Early going to bed minimizes the danger of the disease. Furthermore he is thus removed from association with healthy persons. He should be provided with his own toilet articles, eating and drinking utensils, which should be sterilized by boiling after use. All discharges from coughing and sneezing should be collected on a piece of gauze and destroyed by burning.

"2. The attendant should be extremely careful not to touch his own face or mouth with his hands while handling the patient or infected articles in the sick room, and should cleanse his hands with soap, water and a nail brush, and hold for five minutes in antiseptic solution (1 in 40) carbolic, or (1 in 1,000) bichloride, on leaving the patient. In this way the attendant will protect himself from the disease, and if he washes his hands thoroughly will not carry the disease to another.

"3. Every person should endeavor to maintain the highest standard of general health by taking suitable exercise in the fresh air, eating wholesome food, and sleeping with the windows open and arranged so that no draught is produced.

"4. Crowded places such as street cars, mass meetings, moving picture shows, theatres and other gatherings should be avoided at this time.

"5. Kissing should be avoided.

"6. No food should be taken without previously washing the hands, and the hands should be kept away from the mouth and nose at all times.

"7. The nose and mouth should always be covered with a handkerchief in the act of coughing or sneezing.

"8. All persons, especially those engaged in factories, large business establishments, etc., where a number of people are congregated, should report on the first sign of illness and be relieved of their duties. To endeavor to fight off the disease by continuing at work not only renders the severity of the illness more severe, but also exposes others to the disease.

"9. The symptoms in typical cases are as follows: An acute and sudden onset with headache, intense, just behind the eyes, pain in the small of the back, and sometimes in the region of the stomach, elevation of temperature from 101 degrees to 104 degrees with comparatively slow pulse rate. The face is flushed, the tongue coated, and in every case there is some redness of the eyes Great prostration is experienced and the patient usually lies in bed in a 'huddled-up' position. In some cases sore throat and cough are noted, and with many only part of these symptoms are found.

"The temperature becomes normal and the patient recovers within five days, providing complications such as pneumonia, middle ear diseases and affection of the heart do not occur. These may be avoided by prompt and careful treatment.

"Consult your physician as soon as you have reason to suppose that you have the disease."

Putting off an easy thing makes it hard, and putting off a hard thing makes it impossible.

Work as if you owned the place—and perhaps you may.—Elbert Hubbard.

The Buying of Second-Hand Machine Tools

The Age of a Machine and Its Serial Number Are Facts That the Purchaser Should Have Information About—Things That the Purchaser Should Watch With Great Care

By DONALD A. HAMPSON, Assoc. Mem. Am. Soc. M. E.

IN these days of machine tool shortage, every shop has to consider the possibilities of second hand machinery. Some shops, because of limited capital, never buy a new machine at all. It is possible to get satisfactory, profitable service out of a second hand machine tool just as it is possible to get horribly "stung." Any man who has read the advertisements in trade papers for years and studied the photos of machine tools should know pretty nearly all the makes of each kind of tool—if he is one of the coming men, he has formed an idea of the relative value of each and he has mentally adapted certain machines to the work in his own shop. Further, if he has been a student of catalogues and has occasionally asked the price of tools, he should be fairly well qualified to purchase equipment provided he uses his judgment in the matter of prices.

To such a well read person, a visit to both new and second hand displays in show rooms is more or less of a delight—also, if he has been located far from great mechanical centres, it will show to him very little in cold iron and steel that he was not familiar with, on paper at least. In this respect, the man who hails from Mullenfield and who has faithfully studied these aids that the mail has brought to him is generally broader and better informed than his brother mechanic in the great city who has worked in dozens of shops and knows other dozens that hold out good jobs just around the corner.

The Age and Serial Number

The age of a machine and its serial number are facts that should be known when purchasing a second hand tool. Frequently a dealer will say that such and such a machine is a "model 4X, about two years old." The dealer may be perfectly honest and yet there may never have been any but a model 4 made in that size. The writer has found that in most establishments of this kind the salesmen and mechanics know but little about machine tool lines outside of lathes, planers, drills, and millers and often very little wide knowledge of these; when it comes to automatics and keyseaters and turret lathes and vertical millers, they soon confine their talk to generalities in the presence of an advertisement reading man. The latter must select for himself.

During the last four years the sale of emery cloth must have trebled. With no purpose other than to see how some of the smaller places were conducted, the writer went the length of Centre St., in New York, one afternoon ostensibly in search of a No. 2 miller. Almost without exception, the owners were Jewish and ready to do business at any reasonable price—without exception all the places had gangs of men scrubbing for dear life to get the rust and oil off the tools on the floor. Some of the places were smart enough to do the cleaning in a back room, some didn't care, and the emery cloth scraped away right inside the door. Where all the old machines came from is a mystery—any student of the business could and can tell at a glance about the decade in which a machine tool belongs—the oil collecting base, the box type of construction, the belt drive, the absence of outside ribs, their presence, and the artistically curving legs—each is the type of a period as surely as the Ionic and the Doric in architecture.

There are second hand firms with a reputation and a rating that rebuild tools that go out just as good in all respects as new, and that sell a tool that has not been rebuilt on a satisfaction-or-money-back plan; such firms know the products of the past and present right to the last feed pulley and it is a pleasure to do business with them.

This Shop Was Ear-marked

Other houses quote on a machine that has been "overhauled and is in first class condition." Too often the overhauling is of the same kind that Will's boy did on their Ford and the machine, though marvelously polished, has been taken apart and reassembled by a helper of the class that puts "burrs" on chamfered side first. I was looking for a turret lathe in a good sized warehouse not long ago; turret lathes were in the far end of the building and passing down the aisles I made excuses for stopping at other tools on the way. They didn't show much sign of wear and yet I wasn't impressed. Just as the salesman and I reached the turret lathes, a messenger called him back to the office to get a long distance message from N.Y. While he was gone I slipped into an adjacent building which was evidently the "shop" where overhauling was done. No one was in sight then but two boys who were filing industriously on the ways of some large lathes. I asked one of them what he was doing and he said, "Dunno mister, the boss told me to file these marks out (scored V's)—I only come here this morning. Say, I wonder why they don't file these out oftener and make it easier for guys like us." That was all I wanted to know about that place. It didn't take long to decide that the turret lathes were a bit high in price—or so I told the salesman when he reurned—high at any price.

Go Over the Tools Yourself

The best plan is for the prospective buyer to get permission to go over a machine himself. To do this he should go prepared to work in the dirt and have a wrench or two, a scraper, a screw driver, and a twelve inch straightedge (at least) with him for tools of this sort seem to be as scarce in such places as they are in some garages. Permission to investigate the condition of a machine tool is readily obtained and should be taken advantage of; many a weak spot, worn or broken, will be unearthed in this way and again the good condition of another machine will be shown beyond doubt, giving one a feeling of security in writing out the check for the same.

Up in a northern city, the writer was giving an automatic screw machine the "once over" some time ago. Next to the automatic was a No. 5 Brown & Sharpe miller that had been cleaned and polished and repainted until it looked like new. It had really been well overhauled—ways replaned, bearings scraped, worn parts faced up true—but while I was there they did a final job that queered the whole thing. Someone had gouged the table with a cutter leaving a depression an inch wide by about four long. I should have left that as it was or until I had a chance to clean it out with an end mill and set in a piece with three small screws, but in the second hand business appearances count. So along came a husky "wop" with chisel and hammer to fix up the spot. And he really was an artist with a chisel, cutting out a recess nearly an inch deep in a very short space of time (the gouge was only an eighth deep.) Then he produced a piece of steel from his kit which he drove in the hole, peening it down all around the edges until no trace of gap was left. A half hour's work with a coarse file and the spot couldn't be located, but—I thought, "after that peening and the peening effect of the chiseling, how straight are those nicely planed ways?"

The Serial Number Tells It

If the serial number of a machine has been secured, the maker can tell you when the machine left his plant. This is a help, but is not an infallible guide as to the condition of the tool because some machines may have been forced to the limit and had no care while others may have run a few months in a plant which has gone into bankruptcy and left the tools standing for years affected only by the oil and chips that hadn't even been wiped off.

For my own part I prefer to buy a machine as it was used, not "thoroughly cleaned and overhauled." Before that machine gets to work in your own shop, it invariably must be taken apart fore some adjustment or adaptation and during that period you can make your own repairs and clean up. A substantial reduction can usually be secured for taking a machine off the floor "as it stands"—enough to pay for the subsequent overhauling that will be done under your own eye. Except in the better class of dealers' shops that have been mentioned, it is customary to take any machine tool needed in the repair department from the stock coming in and overhauling is done on machines that wheeze and jump and move at the rate of 15 feet per minute. I saw a planer on skids just as it had come out of the freight car planing the table of another planer and I mentally compared the work with what we could do in our own shop where our twelve foot planer would cut straight to a cigarette paper in that length; the "machine tool' in the above named case certainly must have been built before the Civil War.

Many Things Bear Witness

Various telltales are apparent as one looks over a tool. For instance, most tool builders use cap screws and set screws of their own make and design—a little better finished than stock screws, usually case hardened. In the course of years' service these screws get lost or broken and stock screws are substituted; the subtitution of these odd and random length screws in any great proportion is a good indication of long or careless usage. The condition of gear teeth on main drives shows how much pulling has been done—if the clearance between two mating gears is a minimum and the tooth outlines as viewed from the side are sharp when the dirt and oil is cleaned off, that is a good indication of little service or careful usage. Chips tell a story: the presence of them packed in out of the way places, discovered when taking apart, generally means long years of service. Chips of brass only indicate that the machine has done light work, though the speeds may have been high and bearings have suffered accordingly.

The countershaft often tells something about the machine itself. If the hanger bearings fit reasonably well and the loose pulley shows unusual wear, it is a sign that the machine has stood idle much of its time and should be in good physical shape. The lack of the usual shiny coat of paint on overhauled tools lost one sale not long ago. The buyer had examined the machine all around, tried the fits, used a bar to detect any play in spindles and slides, and was about to OK the deal when he noticed witness marks on the spindle boxes—home made ones. Taking the caps off and the brasses out showed a bad case of wear.

Ship Building on the Clyde

Fighting the Flu

WHEN Spanish Flu gets after you and says, "Look here, John Henry, I'm going to hand you a jolt to linger in your mem'ry," don't stop to argufy the point, just touch him on the vest, and say, come on, S.F. with me and be my Sunday guest.

It ain't no use to spar with him or side-step from the Flu; this Spanish gent he sticks, by heck, just like a hunk of glue.

So take him right along with you and put him in your bed, stick water bottles on his feet and a pillow 'neath his head—and fill him up right to the neck with senna and sage tea—and dose him up with liver salts and soak him one, two three.

And plaster mustard on his chest to puncture through his hide, put turpentine and vinegar upon his back and side.

Put camphor oil upon his pipes, stick pills into his throat, and jam him full of purgatives and strive to get his goat.

And old S. F. will stay with you, he'll camp upon the job, to get your help at pushin' up the daisies through the sod. He'll roost upon your shoulder blades, he'll sit upon your dome, he'll pay a visit inch by inch to every rib and bone.

He'll put ten men inside your head with shovels and with picks, he'll put a dozen on your back a-peltin' stones and bricks.

So when you see him comin' now don't stop to fuss around, because he's got you faded when it comes to coverin' ground. Just crawl into your little cot, for senna get a thirst—for if you don't old Spanish Flu may rise and swat you first.—ARK.

The printer sometimes makes you say all sorts of things. Thus last week it was recorded in this paper that a boat launched at Port Arthur had an engine with cylinders 20½ ft., 34½ ft., 55 ft. and 40 ft. When inches grow into feet at such a reckless rate anything's liable to happen. However, we haven't got to stoke to keep that tremendous engine going.

* * *

The *British Trade Review* in a recent issue said:—In Canada there has been instituted a rationing system for householders by which supplies will be given for next winter up to 70 per cent. of last winter's supplies. Amongst other steps to be taken to deal with the situation is the erection of a briquetting plant. This has been done on the recommendations of the Advisory Council for Scientific and Industrial Research, which has considered the possibilities of utilizing the coal supplies of Western Canada at points other than those in the near vicinity of the deposits. Western Canada has immense deposits of coal, but it is of poor quality.

If the chap who made that reference to Western Canada coal has not been fighting on the western front, he can have all the sensations of war by going to Western Canada and looking up the Alberta coal operators.

* * *

Fire losses in Canada amount to $30,000,000 annually. On economic grounds such waste is folly. Canada is faced by a national debt of almost $1,250,000,000. Can the people of Canada afford a national bonfire costing $30,000,000 a year? On patriotic grounds, such waste is a dereliction of duty. The ravages of fire cost more than money. Fire takes its toll in food, in munitions and in clothing and equipment, all of which spells loss of life "over there." Germany's strong ally is the fire scourge of the United States and Canada.

Principles and Practice of Mechanical Drawing

In Article Six the Author Takes Up Conventions Relating to Finish Marks, Dimensioning, Notations and Lettering.

By TERRELL CROFT.

Article VI.—Finish Marks and Some Other Conventions

AN example of the value of the ability to render understandable sketches came recently to the attention of the writer. A number of candidates were taking an examination for a first-class engineer's license. This question was asked: "Assume that you have under your charge a condensing alternating-current turbo-generator unit and that you must put this unit, which is standing idle, into service in parallel with another similar unit. Describe the operations which it is necessary to follow in doing this. Name the different devices and apparatus involved and describe briefly the function of each device and its relation to the complete unit."

The answer which was by far the most satisfactory was given by a middle-aged man who had grown up through the ranks. The reason that his presentation was the most logical and understandable was that he submitted a sketch indicating graphically the different components of the equipment and their relation to one another. He was the only candidate who did use a sketch. His rendering was neat, simple, effective and constituted in itself ample evidence that he had studied sketching as a means of bettering his position and prospects. Because of his inclusion of the sketch and his utilization of reference letters on it, his written description was quite brief. He obtained his license.

The other candidates consumed pages of paper in trying to describe operations which they were, doubtless, quite competent to perform. But it is questionable whether anyone, with only these verbose written directions to guide him, could gain a reasonable conception of what the writers were endeavoring to describe.

Finish marks must be used on practically every mechanical drawing or sketch. It is unnecessary to finish certain surfaces of the component parts of machines or equipment. These parts may remain "rough" just as the castings come from the foundry or as the metal stock is received from the jobber. Such surfaces may be painted or otherwise treated, without cutting the metal, to improve their appearance but such a treated surface does not constitute a finished surface as the term is used in machine-construction parlance. On the other hand, there are other surfaces on metal members which must be finished. That is, the metal must be cut off by some process or other to satisfy certain dimensions or to present a certain specified appearance. Thus, there are a number of different kinds of "finishes": chip, chip-and-file, mill, plane, rough turned, polish, scrap, and others. A surface which is to be finished must be so designated on the drawing that the machinist will understand what is required.

As to whether the finish specifications should be determined in the drawing room or the shop is a question worthy of some consideration. The proper answer to this question is determined to a large extent by the organization and personnel of the drafting and production departments in the place where the work is to be done. Unquestionably, if the draftsman is sufficiently familiar with machining operations to specify intelligently the finishes these specifications can be made most economically in the drawing room. On the other hand, if the draftsman is not familiar with machine-shop practice it is then better to merely specify on the drawing in general terms the kind of finish or the result desired. The conduct of the machining operations required is then left to the shop. This procedure permits the shop man to use the machine or method he deems most suitable for the work—but he must get the result.

As an example, holes may be specified as "drilled" whereas they might be more economically, and quite as satisfactorily, "punched." In this case the finish specification regarding these holes on the drawing would be incorrect. It is almost obvious that, where feasible, it is most economical to have all of the machining operations planned in the drafting room. Where this procedure is followed the shop operations can be completed with the expenditure of minimum time and effort. Frequently this result may be obtained most effectively by close co-operation between the shop and the drawing room. The draftsman should at all times work in close harmony with the chief mechanic, his equivalent, or the shop man. If he does this his drawings will reflect a balanced opinion of theory and practice.

The approved method of designating a finished surface is to use a modified "f" drawn across the line of the drawing representing the finished surface as depicted in Fig. 1. The finish symbol is the same as an inclined lower-case "f" except that it has a heavy black dot on its end. The cross line should be drawn transversely through the stem of the "f" adjacent and parallel to the line of the drawing representing the surface to be finished. Often one of the words enumerated in the list above (such as 'chip," "mill," "plane," etc, etc.) is necessarily used in combination with the finish mark to show just the character of the finish which is required.

Finish designations of other types are shown in Fig. 2. At A the finish required on the three surfaces of a keyway slot is designated by using a single symbol with three leaders radiating from it to the surfaces. At B is represented a finish symbol in which the transverse line intersects the line representing the surface to be finished. Finish marks of this type are considered undesirable

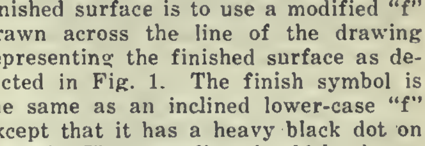

FIG. 1—TWO SURFACES TO BE FINISHED DESIGNATED BY FINISH MARKS.

in some drafting rooms because it is asserted they tend to confuse the outline of the object, and may not indicate definitely the surface to be finished. At C is cited a finish mark lying wholly outside of the outline of the object. The surface to which the character points is the one to be finished. By using different numbers and arrangements of the "hooks" on the symbol a code can be developed whereby finishes of the different characters may be specified graphically. However, experience has shown that it is, as a rule, undesirable to designate the different types of finishes by code symbols. Confusion usually results. The better plan is to designate each surface to be finished with a symbol and to then amplify the symbol with an explanatory note if necessary. The symbol at C was originated by Prof. Fellows. He suggests that a symbol like that at AB (Fig. 3) may be used where all of the surfaces between the two symbols are to be finished.

When a dimension is expressed decimally, as at A in Fig. 1, such specification ordinarily implies that the limiting

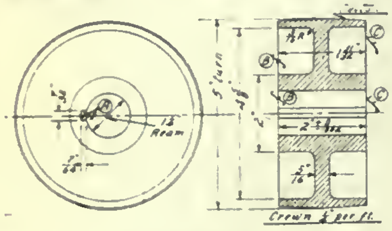

FIG. 2—ILLUSTRATING APPLICATION OF SYMBOLS OF DIFFERENT TYPES TO INDICATE FINISHED SURFACES.

surfaces are to be finished. Obviously, the specifying of a dimension with a decimal to the thousandths place would be inconsistent where the dimension was between unfinished surfaces.

When an object is to be finished all over, the information may be communicated by a notation "Finish all over" or "F.A.O." as portrayed in Figs. 4 and 5.

In specifying the finish for a taper hole which is machined to accomodate a taper pin the operations involved may be explained with a note thus: "Drill

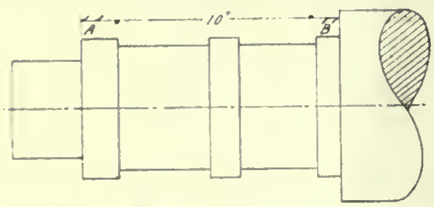

FIG. 3—ONE METHOD OF COMBINING FINISH MARKS WITH A DIMENSION LINE.

7/32. Ream for No. 4 Taper pin," as entered on Fig. 5.

Some special finish markings are defined in Fig. 6. At A "¼" Tap" means that the hole is to be drilled with a smaller drill (13/64 for a ¼" tap) and then a thread cut in its surface with a ¼" tap. A leader from the notation to the hole under consideration ties them together. The surface of a drilled hole is rough and it is impossible to drill accurately a hole to a specified dimension. Therefore, where the diameter of a hole must be of exact dimensions or where its surface must be smooth, the hole must be reamed after drilling. This may be specified "½" ream" as shown at B. Ordinary drilled holes are cited at C. Where a hole must be counterbored to accomodate the head of a cap screw or for some other reason this operation can be specified (D, Fig. 6) as "½" counterbore." The ½-inch specifies the diameter. The depth of the hole

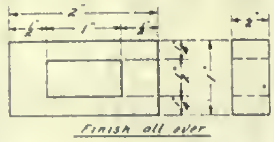

FIG. 4—OBJECT TO BE FINISHED "ALL OVER" OFTEN SPECIFIED AS "F.A.O."

must be given in a note or shown on an auxiliary view as in Fig. 6. The notation (E, Fig. 6) "3" turn" means that the outer surface is to be given no other finish than that provided when it is turned off in a lathe or mill. "Scrape" (F. Fig. 6) means that the surface specified is to be rendered as true as possible by hand scraping. Such a surface should be tested by rubbing on a surface plate covered with a very thin coating of prussian blue or other colored paste. The high spots thus disclosed are then scraped down. The testing with a surface plate and the scraping down of the high spots is continued until no high spots are apparent. "Polish" (G, Fig. 6) signifies that the surface identified by the leader is to be made bright and smooth, after machine finishing, by

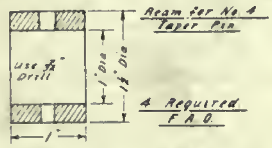

FIG. 5—"DRILL" AND "REAM FOR TAPER-PIN" AND "F.A.O." FINISH DESIGNATIONS.

cutting down with emery or some other abrasive, and then buffing.

The notation "core" (H, Fig. 7) denotes that the surface inside of the casting is to be left rough just as it comes from the foundry. The hole marked "bore" (I, Fig. 7) is to be cast smaller than specified and then bored to dimension in a lathe or boring machine. Note that limits are specified for the diameter of this hole. It may not be smaller than 1.250-inch nor larger than 1.260-inch. Thus a tolerance of 0.01-inch is allowed. The outside surface of this cylinder is to be ground (J,

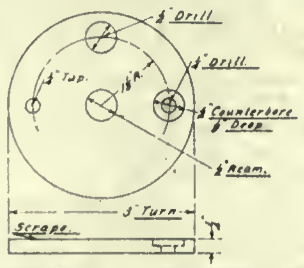

FIG. 6—SHOWING APPLICATIONS OF THE LEGENDS "DRILL," "TAP," "COUNTERBORE," "REAM," "TURN," "SCRAPE" AND "POLISH"

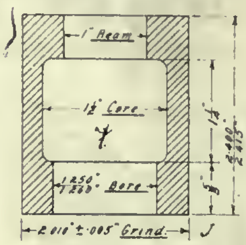
Fig. 7) in a grinding machine. A limit is also specified for this diameter. It may be either 0.005-inch smaller or 0.005-inch larger than 2.010-inch and pass inspection.

"Spot face" (K, Fig. 8) implies that the boss, ½-inch in diameter, extending above the end surface has been provided to permit of its being cut off about flush with the end surface, this to insure an even bearing for a nut or bolt head. The remainder of the end at K may be left rough. The legend "⅝-inch C'bore to surface" (L, Fig. 8) denotes that a circular spot ⅛-inch in diameter is to be faced off flat. That is, it is to be dressed until the roughness of the casting is obliterated and a true surface obtained. No dimension as to depth is necessary in this instance because this specification is used only where tolerance limits of considerable magnitude are permissible.



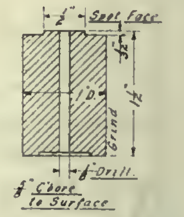


FIG. 7—CYLINDER TO BE "CORED," "BORED" AND "REAMED" INTERNALLY AT DIFFERENT LOCATIONS ALONG ITS LENGTH.

FIG. 8—ILLUSTRATING THE MEANING OF "SPOT FACE" AND "COUNTERBORE" TO SURFACE.

Some practical examples of the application of finish symbols will now be considered. In Fig. 9 the outside surfaces of the drill block are all to be finished as indicated, but the faces of the 90-deg. grooves remain unfinished. This drawing also illustrates the approved method of specifying the magnitude of an angle on a mechanical drawing. Figs. 10 and 11 showing respectively working drawings for a clamp and a shaft present practical applica-

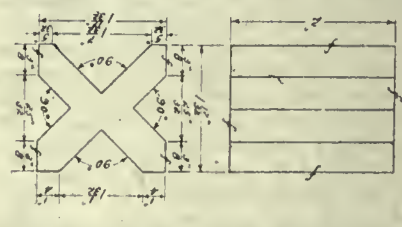

FIG. 9—DETAILS OF A DRILL BLOCK SHOWING HOW THE MAGNITUDE OF ANGLES IN DEGREES MAY BE SPECIFIED AND ALSO SHOWING APPROVED METHODS OF INDICATING FINISHES.

tions of some of the finish marks and specifications which have been discussed in preceding paragraphs. Both of these pictures represent practical working drawings rendered in accordance with the best modern practice. Note particularly on Fig. 11 how the limits and machine operations are specified. Also consider the method of dimensioning, the rendering of threads, construction of the arrow-heads, and the utilization of the sectional view at AA.

Conventional "breaks" can often be used to advantage in mechanical drawing to indicate more clearly the constructional character of some member shown on the sheet. Considerable ingenuity can be displayed in this regard by a draftsman. He may, by showing some member "broken" convey the necessary information about the construction of the piece which would, if the break were not shown, require several views for its complete definition. In Fig. 12 are exhibited the more important breaks used on drawings. Where a long thin member such as a pipe or rail or an I-beam is to be detailed it is unnecessary to draw a short length of the piece and then "break" a portion out of the center, using one of the conventional breaks shown in Fig. 12. The overall dimension given on the sheet will indicate the exact length required of the member.

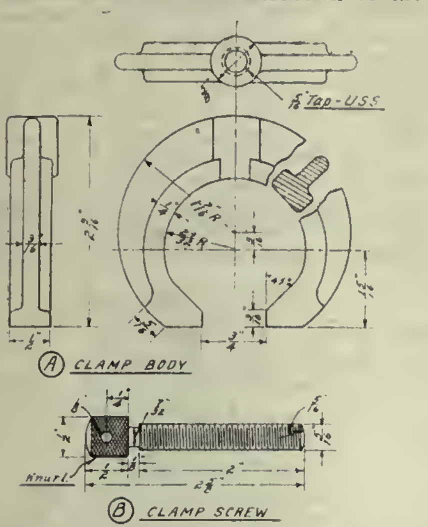

FIG. 10—WORKING DRAWING OF THE DETAILS OF A CLAMP. THIS ILLUSTRATES GOOD PRACTICE IN INDICATING FINISH, IN DIMENSIONING AND IN GENERAL RENDERING.

The language of lines in mechanical drawing is interpreted graphically by Fig. 13. The fact that mechanical drawings constitute a language universally understood by those familiar with engineering matters has been explained ni preceding sections. It has for many years been the practice to utilize, in rendering mechanical drawings, lines of different characters to represent different things or ideas. Many of the conventions thus adopted are universally applied, while others are employed but seldom. Obviously, it is a very bad and confusing practice to use on a drawing only two or three kinds of lines. When this is done the drawing does not appear complete and it is difficult of interpretation. The essential requirements of the lines of the different characters are three:

(1) They should be readily distinguishable from one another.

(2) They should be capable of being made easily.

(3) There should be considerable contrast between them to insure ready interpretation and good appearance.

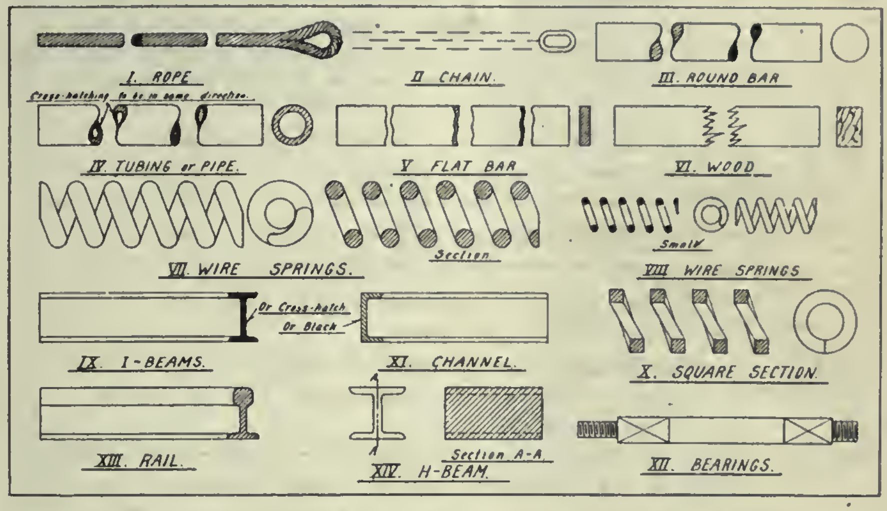

FIG. 12—SOME CONVENTIONAL "BREAKS" EMPLOYED IN MECHANICAL DRAWING.

The second requirement—that of ease of production—is of particular importance with the lines which are made most frequently. The symbols of the chart of Fig. 13 represent, it is believed, the very best practice. The lines of each of the types exhibited in Fig. 13 will now be considered individually. Practical applications are given in Fig. 14.

The visible outline (A, Figs. 13 and 14), sometimes called a boundary line, is used to indicate any visible edge, boundary or sharp break of a surface, which is invisible from the location from which the object which is shown in the drawing is viewed. It is in ordinary mechanical drawing to be made quite heavy—the heaviest line on the sheet with the exception of the border line—and it is to be continuous. It is made heavy to emphasize the contour of the object.

Invisible lines (B, Figs. 13 and 14) are used to show any edge or border of a surface when that edge or border is concealed from view. A dash line comprising relatively short dashes is used. The dashes may be from 1/8-inch to 3/16-inch long with a 1/32-inch open space between them. The invisible line should be somewhat lighter (thinner) than the outline to insure contrast. Whenever two lines consisting of dashes are drawn parallel and close together, the breaks between the dashes should be staggered. Where this is done the course of each broken dash line can be followed more readily by the eye.

Center lines (C, Figs. 13 and 14) are imaginary lines drawn through the centers of symmetrical views and are used as reference lines. The object of the drawing is, or certain parts thereof are, symmetrical around the center lines. In laying out a drawing or sketch usually the first step is to plot the center lines. They should be very light and composed of alternate dots and dashes. The dashes should be about ¾-inch long and the dots 1/32-inch long. The spaces between should be about 1/32-inch.

Dimension lines (D, Figs. 13 and 14) are the lines which identify the points between which dimensions are given. On mechanical working drawings on tracing cloth for blueprinting it is universally considered good practice to make dimension lines very fine unbroken black lines, except where an open space is left for the figures indicating the dimensions and the notations. On each end of a dimension line are arrow-heads or barbs. These should be distinctly and neatly made (Fig. 15-1 and 11). The sides of the arrow-head should spread slightly away from the dimension line, but not too

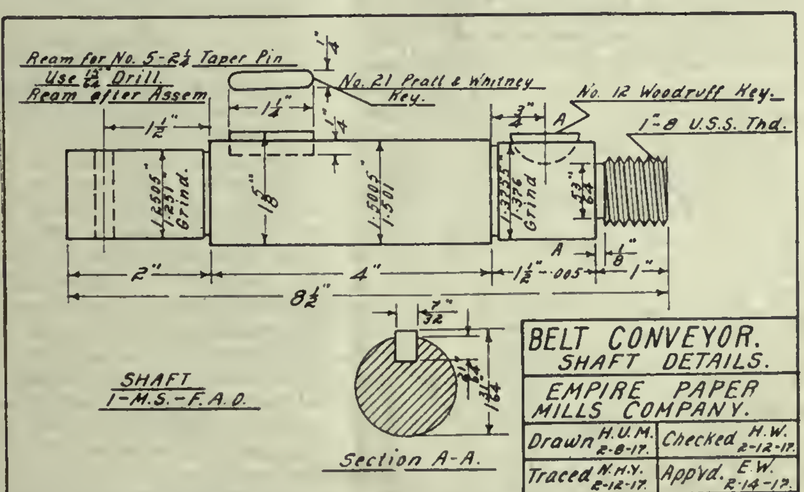

FIG. 11—WORKING DRAWING OF A CONVEYOR SHAFT ILLUSTRATING GOOD PRACTICE IN SPECIFYING LIMITS, IN INDICATING THREADS AND IN DIMENSIONING, NOTES, ARROWHEADS AND SECTIONING

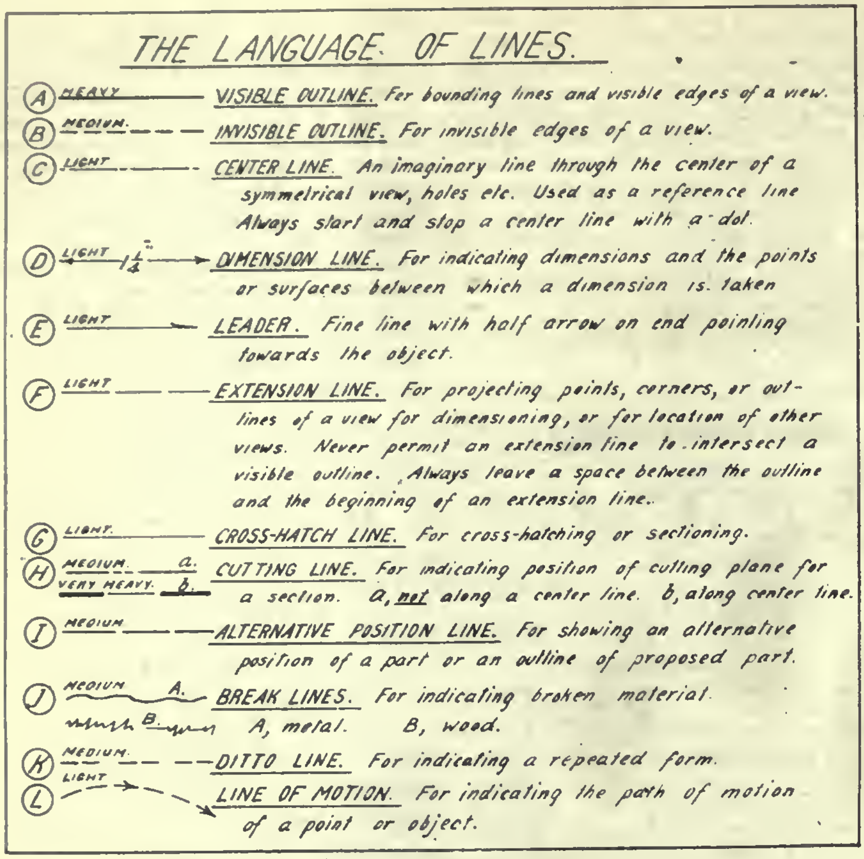

FIG. 13—A CHART SHOWING THE LANGUAGE OF LINES.

far. Only two strokes of a pen are necessary (III, Fig. 15) to make an arrow-head. Where drawings must be reproduced for zinc etching line cuts, a dotted dimension line gives more contrast and hence is more readily understood than a fine unbroken dimension line and is, therefore, frequently used for this purpose.

The leader (E. Figs. 13 and 14) is used to point to and designate some surface, hole, or other feature concerning which a notation or explanatory legend is necessary. It comprises a fine light line with a half arrow on one end. It may be either straight or curved. Where the draftsman is skillful, the leader line may be drawn free hand. Where he is not, it should be drawn mechanically with a ruling pen or compass. Note that the end next to the object should terminate in a half arrow (Fig. 15-IV) and not in a complete arrow-head as used on the end of a dimension line. The end adjacent to the note or legend need not have any distinguishing character on it.

The extension line (F, Figs 13 and 14) sometimes called a projection line, is an imaginary line used to project lines or points for dimensioning or to connect in the drawing the same surfaces or edges in different views. For example, an extension line may be used for projecting the position of a surface or edge in one view—possibly the side view—to the position or edge of that same surface in another view—perhaps the top view. Extension lines are fine lines made up of dashes ½ to ¾-inch long and with small spaces between them.

The cross-hatch line (G, Figs. 13 and 14) is used in shading cut surfaces. Ordinarily they are quite light and continuous, and drawn about 1/16-inch apart. However, they may, if some convention symbols have been adopted to indicate the sections of different materials, be dotted or of varying weights as occasion demands. The application of sectioning and section lines has been treated in some detail in a preceding article.

A cutting line (H-a, Figs. 13 and 14) sometimes called a cross-section line, is used when it is necessary to show where a section is taken through an object. That is, a cutting line may be drawn through the view to represent the edge of the cutting plane. This line should be of medium weight and should comprise long dashes separated at equidistant intervals by two short dashes or

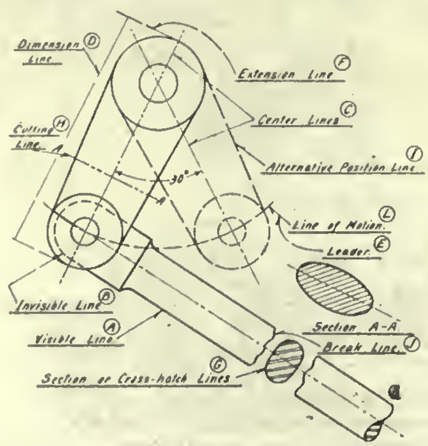

FIG. 14—ILLUSTRATING THE APPLICATION OF THE LINES OF DIFFERENT TYPES.

dots. Sometimes the alternate cutting line shown at b is employed when it is necessary to take a section along a center line. One heavy dash is drawn on the center line at the beginning and another at the end of the imaginary cutting plane. Different combinations of letters are used to designate the different sections which may be taken on a drawing. Thus in Fig. 14 at H the section is designated by the letters AA.

The alternate position line (I, Figs. 13 and 14) is used where it is necessary to show the second position of some other part that may interfere or for which clearance must be provided. This line

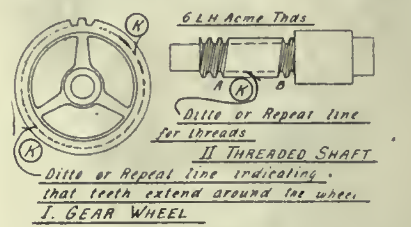

FIG. 14A—SHOWING APPLICATION OF THE DITTO OR REPEAT LINE.
(The form or contour of which the ditto line indicates a repetition should always be shown one or more times before the ditto line is used).

is made of medium weight and the dashes ¼-inch to ⅜-inch long.

The break line (J, Figs. 13 and 14) is used where a part of a view is broken away. This line is drawn very irregular to insure that its significance will be obvious. Refer also to Fig. 12.

The ditto line (K, Figs. 13 and 14A) is used for indicating a series of forms such as gear teeth and the like.

A line of motion (L, Figs. 13 and 14) is used to designate the path of the

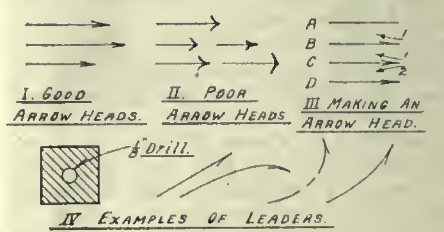

FIG. 15—EXAMPLES EXPLANATORY OF GOOD PRACTICE IN LINE SYMBOLS.

motion of a point. This symbol must be used often in machine drawings to insure the provision of proper clearance and proper arrangement. It comprises a series of very short dashes.

The lettering of a mechanical drawing is a feature the importance of which is often under-estimated. There is no other one thing which is so effective in giving tone and a business-like appearance to a drawing. A poorly-rendered drawing well lettered may present an attractive appearance. But on the other hand, no matter how well a drawing is made if it is poorly lettered it will look like a botched job. The lettering characters should be such that they may be read with minimum effort, which necessites a plain outline and uniform spacing, and they should be such that they can be made easily and rapidly. All lettering should be freehand.

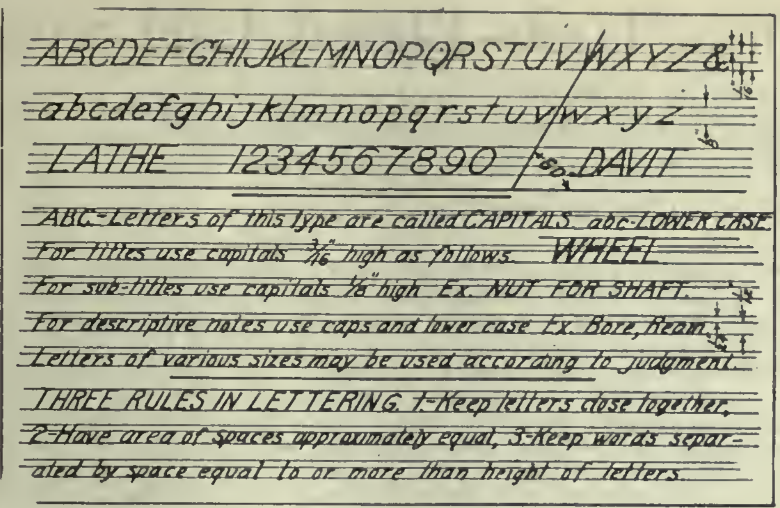

FIG. 16— LETTERING OF THE STYLE WHICH IS MOST SUITABLE AND ECONOMICAL FOR MECHANICAL AND ENGINEERING DRAWINGS.

To acquire the ability to letter, careful, faithful, and intelligent practice is necessary. It appears that there are few who cannot, with the expenditure of a reasonable amount of effort, develop the knack of lettering. Because an individual is a good writer does not mean anything one way or the other in so far as his capacity for lettering is concerned. Some good letterers are also good writers, but many are not.

As to the type of letter which should be adopted it is now usually conceded that the inclined Gothic or the so-called "Reinhardt" modification thereof is the preferable one for engineering drawing. This letter (Fig. 16) is simple and readily executed. Charles W. Reinhardt, who was for many years chief draftsman on the *Engineering News* made a study of lettering for engineering drawings and has prepared a very valuable brief treatise "Lettering for Engineers, Draftsmen, and Students," in which he described in detail the methods whereby one may become deft at the art of producing freehand letters. The simplicity of the system will be apparent from a consideration of Fig. 16. This type is used very extensively in engineering offices and machine drafting rooms.

In constructing freehand letters note that all are based on the oval and straight line. The slant of all the letters should be uniform and may be taken at some one angle, which may be one between 60 deg. and 75 deg. It is frequently desirable to adopt a 60-deg. slant because 60-deg. triangles are available for drawing pencil guide lines.

The size of the lettering to be used on any sheet should be determined by the purposes and character of the words which are to be used. For titles, capitals—frequently drawn vertical—about 3/16-inch high, constitute good practice. For sub-titles, letters ⅛-inch high may be employed. The notes and explanations should comprise only lower case letters. There are two reasons for this. First, it is much easier to read lower case letters than it is capitals. Second, the lower case letters can be made more rapidly. The bodies of the lower case letters should be equal to two-thirds the height of the capitals. In lettering pencil drawings a soft pencil—about 2H—should be used.

GERMANY'S SHORTAGE OF TUNGSTEN

By R. E.

Tungsten, a metal discovered by a Spaniard, is the principal ingredient in the manufacture of high-speed tool steel, and plays such an important part in the manufacture of projectiles, armour plates, gun boring, etc. Tungsten ore was found chiefly in the United States of America, Bolivia, Peru, Burma, Siam, China, Japan, Malaya, Australia, New Zealand, Spain, Portugal, England, and to a small extent in South Africa. Even before the war, the high-speed industry had secured an annual turnover of more than £300,000, and doubtless a comparatively small outly of £25,000 or £30,000 on the production of tungsten powder in this country previous to 1914 would have saved us a vast amount of money and much anxiety in the production of munitions. Thanks to the British Navy, Germany, which had been reaching out her hands to control the industry, was suffering from a shortage of tungsten amounting almost to famine. Owing to the greatly increased production of tungsten powder in the United States, where the output has risen during the war from 1,400 to 7,000 tons a year, and also in the British Empire, and again, in Siam, Britain was no longer dependent on Germany for any of the alloys used in the making of high-speed steel, while there are within the bounds of the British Empire ample resources to meet all our requirements if only the industry is properly fostered and encouraged.

AN ELECTRICALLY EQUIPPED SHIPYARD

By MARK MEREDITH.

During his tour of inspection of the shipbuilding areas of the North-East Coast, Lord Pirrie visited the Egis Yard. This yard, on which work was begun in November, and is now nearly completed, covers a site of nearly 16 acres, and is interesting from the fact that the whole of the plant is driven by electricity. The yard has four berths, each capable of building a ship 430 feet long by 56 ffeet beam, and of about 10,000 tons of deadweight. The principal buildings are erected on either side of the berths. On the south is a plater's shed 532 feet long by 100 feet broad, which contains all the most up-to-date electrically driven machinery for working the steel material. Direct gas-firing furnaces for frame and plates are installed.

The means of erecting the materials, when worked on to the slips, is provided by 20 steel derrick posts, 98 feet long, with 35 feet derricks, four on each side of each ship, with an independent electric winch capable of lifting 3 tons to each derrick. Six other portable electric winches are also provided for use when required. On the fitting-out quay 466 feet long, where the vessels will be fitted out after launching, is a 30-ton electrical driven travelling crane capable of lifting 30 tons at a radius of 54 feet, and 10 tons at a radius of 98 feet. The various stores and shops are all equipped with the latest and most efficiency machinery, and electrical power, lighting pneumatic piping, water pipes, are taken down between each berth, providing every facility for utilizing pneumatic power to the greatest possible extent. The plant is driven throughout by electricity supplied on the three-phase system.

CANADA'S SEA CONNECTIONS

By M. M.

In view of the progress now being made in Canada with the shipbuilding industry, more enterprise is being shown there than in any other part of the Empire. It is of interest to hear that important negotiations are taking place for a big development of shipping services between this country and the Dominion. Much, however, depends upon the settlement of the railway question which Sir Robert Borden has in hand, and with which it is understood he has made good headway since his visit to London in connection with the Imperial Conference. The Cunard Line is one of the companies vitally interested, as over a year ago it arrived at a working arrangement with the Canadian Northern Railway for an expansion of the country's overseas commerce, both on the Atlantic and the Pacific; and is naturally being held back pending an agreement between the various parties concerned. Another question to which it is said Sir Robt. Borden is to give prompt attention is the report of the Quebec Board of Trade for a prolongation of navigation on the St. Lawrence, between that port and the sea, throughout the year. If carried out, there is no doubt that the recommendations of the committee will make navigation on that river easier, but until an improvement is reflected in underwriters' statistics there can, be no possible reduction in premiums.

Operation of Machine Tools Effects Fuel Saving

Coal is Only of as Much Value as We Get Out of it—Proper Care and Operation of Machine Tools Means Lower Production Costs, and More Important Still, the Conserving of Considerable Fuel

By J. H. RODGERS, Associate Editor

WAR and waste demand conservation. Pre-eminent among the problems of the present day is the urgent need to save both food and fuel. Production has been so seriously interfered with that the shortage in many instances has approached a stage bordering on famine. Fortunately we in this country have not felt the full effects of warring conditions, but the experience of the past year in particular has been sufficiently vivid to impress us with the dire necessity of conserving to the utmost these two prime essentials of human maintenance. Last winter's coal scarcity is still fresh in the memory of most of us, and therefore, it behooves us to avoid, as far as possible, a repetition of such conditions. The saving of fuel is a problem of such magnitude that a comprehensive study of its many features would require the work of months or years to thoroughly grasp its fullest significance.

The fundamental value of coal is the potential power contained therein. With the production of the mines away below the industrial and domestic requirements, the problem becomes one of utilizing to the fullest extent every ounce of power contained in the quantity of coal that is now available. When the saving of fuel is mentioned we invariably turn our thoughts to the actual burning of the coal, as if this was the only place where the real objective could be attained. Undoubtedly the actual combustion of the coal for the production of heat units is the elementary factor that must be considered for a satisfactory solution of this problem, but it is by no means the only one. The burning of the coal is only the means to an end. In the achievement of this purpose many elements are obviously involved that are more or less important as fuel saving factors.

The heat from the burning coal must necessarily be transferred to various agents before the desired object is finally accomplished. The primary agent is the steam generated from the boiling water, this steam in turn transferring its power to the piston of an engine or the blades of a turbine, from which the power is again transmitted to the various machines by means of suitable mechanical equipment—or may be utilized in the operation of electric generators for power or lighting purposes.

Friction means power lost

With a little study it will be seen that the sole duty of the coal—apart from its actual heat giving value—is in overcoming the friction and resistance incidental to the operation of machinery, or processes, for manufacturing purposes. Very frequently the management of large industrial works look to the power plant staff for assistance in solving problems relating to fuel or power development. In the case of the latter it is mainly a question of ample and suitable equipment, but when the two extreme factors of maximum power and minimum consumption of coal is required the satisfactory solution is far more complex. In analyzing this fuel saving problem it might be well to look farther from the boiler and engine room than we are generally accustomed to do. Broadly speaking, the industrial conditions have greatly changed during the past few years. What would have been considered maximum production three years ago would be classed as poor practice at the present time. This has been brought about by the heavy demand for war material and the opportunity of manufacturers and machine tool builders to concentrate all their efforts in one direction, namely, the development of machinery and accessory equipment for the achievement of a specific object. In some respects the old meaning of competition has been virtually eliminated, as every tool builder is taxed to the utmost in supplying the present and future requirements, but this emulous contest is still continued in producing special tools to meet the ever increasing demands for greater rigidity in design and greater production capacity.

To meet the possibilities of the improved qualities of cutting tool steels, greater power is required to work these tools to their fullest capacity. In order that the additional power could be transmitted to the cutting tool it was necessary to change the proportions of the machines and strengthen many of the parts. In addition to the improvement made to standard equipment many special machines have been constructed for specific shell operations. One noticeable feature that predominates in munition making machinery, particularly on the rough turning and boring type is the greater bearing surfaces that have been given to the movable parts. The spindle bearings are much longer and diameters greatly increased, especially on those boring machines where the shell chuck is contained within the spindle. Greater length and width of ways are used on the carriage and cross slides, so that in many cases the frictional area of the movable parts have been more than doubled and likewise the weight of the different pieces. Therefore, before useful work can be performed on such machines sufficient power is required to overcome the friction of these parts. The amount of this resistance depends very largely on the ability of the operator.

Labor and Operating Efficiency

Under normal conditions selected labor would assist in maintaining the efficiency of the machine, as good mechanics will usually take a special interest in the care of the tools under their charge. With the class of labor now available, and under the system of piece work, little consideration is given to the machine itself, as every effort is spent in what the men think is along the lines of maximum production. It is quite safe to say that few machine operators stop to consider the relative connection between their work and this need of fuel conservation. Nevertheless, it is essential that each individual take a personal interest in this question. In the operation of machinery a large portion of the power transmitted is absorbed by the moving parts, so that the effective work is reduced to the extent of such resistance. It should be the duty of each operator to see that this machine friction is kept down to the lowest possible fraction. Time should be taken each day, and when necessary at intervals during the day, to thoroughly lubricate every portion of the machine where oil will assist its operation. This does not imply that all friction surfaces should be profusely treated with oil, but that sufficient should be used at all times to eliminate all unnecessary resistance to the moving parts. In many large manufacturing plants the lubrication of the transmission is under the direct supervision of a man appointed for the purpose, and in some instances this practice has been extended to the main bearings of the individual machines. However, unless the details of machine lubrication are taken care of by this method, the practice might still be detrimental to efficient machine operation.

Irrespective of any system that may be adopted for general lubrication, there must still be certain details that can only receive attention by the operator in charge. Chief among these is the lubrication of the slides on the carriage or turret heads. Generally the spindles or shaft bearings on machines are protected from flying dust or cuttings, but this is not the case when open slides are used. In order to maintain rigidity of the carriage and cross slide, it is imperative that the gibs be adjusted to avoid any semblance of lost motion. However, these slides must be free enough to move without too great an effort, so that continual care must be exercised in their maintenously aecets the accuracy of the slide entirely free of dust and cuttings, so that in time the fine particles work their way between the surfaces, increasing the power required to move the parts. To make these work easier many operators will slightly release the gib, thus adding to the space between the parts and likewise affecting the rigidity of the tool.

Others will flood the slides with oil after carelessly removing the exposed dust; this is probably worse practice than backing off the gib as the oil and grit act as a grinding compound that in time seriously affects the accuracy of the slide, without materially aiding its movements. Before applying oil to the parts that are exposed to dust or cuttings, the slides should be carefully wiped clean and just sufficient oil used to give a thin layer to the surface. In addition to this it would be good practice to thoroughly clean the ways several times a week with kerosene.

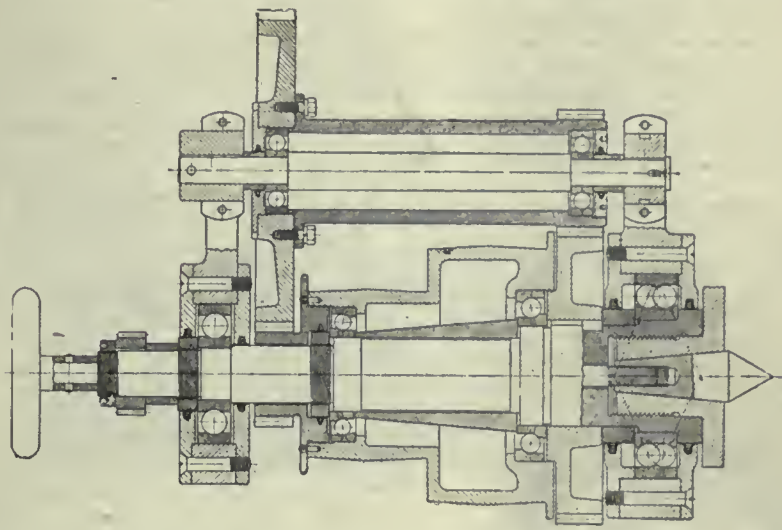
The writer has often experienced the effect of carriage lubrication in the manipulation of saddles on large lathes. The free movement of the carriage is often so gradually affected that an operator may not realize the effort he is putting forth in moving it along the ways. When the slides are dry or choked with fine dust, it frequently requires ten times the power to operate the carriage. This condition also applies to thrust bearings. It may be that the cylindrical portion of the bearing is well lubricated and free running when the machine is not operating under load, but with work in progress the friction of the thrust portion is excessive, owing to the absence of oil. This can be readily seen in the cross feed screw, as a detail under the direct control of the machine operator; very often a drop of oil between the thrust collar and its seat will remove over 50 per cent. of the resistance.

In connection with the saving of fuel these various mechanical details of machines may appear almost insignificant but in plants where hundreds of machines are in continual use, the power required to overcome this friction is no small matter, so that a more careful consideration of this feature might well serve as a basis for the reduced consumption of coal, and at the same time maintain the maximum efficiency of the various machine tools.

THE "DRAGON" BALL BEARING

The "Dragon" bearing is a new and distinctly different type of ball bearing which the Fafnir Bearing Company of New Britain, Conn., has recently begun to manufacture. This bearing involves new principles of design which make it much more efficient than the ordinary ball bearing for certain kinds of service. A large number of these bearings are already in use; and, in every instance, they have proved very efficient.

Although the accompanying cuts quite clearly illustrate the salient and distinctive principles involved, they may well be supplemented with a few words of description. To begin with, this bearing is a double row ball bearing, manufactured in standard single row widths, in each instance containing approximately double the number of balls of the corresponding single row bearing. This very advantageous feature in the construction of the Dragon bearing is made possible by the fact that the two rows of balls are staggered in relation to one another. Furthermore, this intersecting of the two rows of balls renders superfluous the use of a ball retainer, since the balls automatically space one another and travel around the race paths with a total absence of spinning.



COMPLETE BALL BEARING APPLICATION.

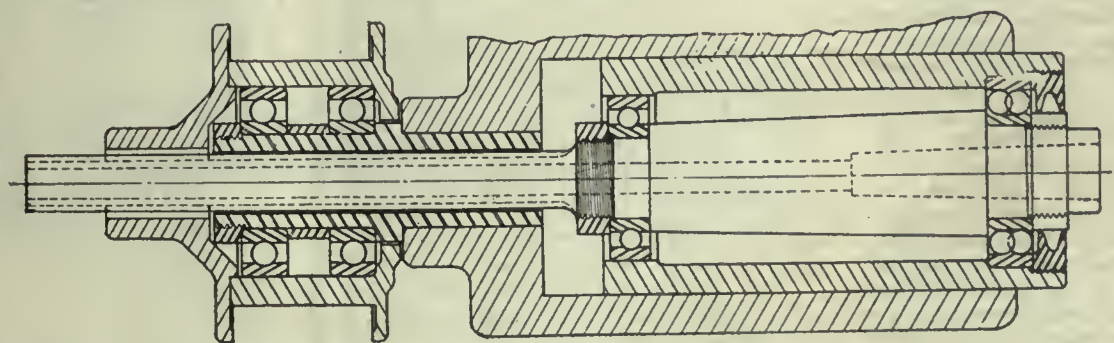
On account of the greater number of balls, the bearing will easily carry fully as much radial load as a single row radial bearing. Moreover, since it is an angular contact ball bearing, in which the load lines of the two rows of balls are mutually opposed, the Dragon bearing will carry, in addition to the aforementioned radial load, a tremendous amount of thrust load in either direction.

The significance of this important feature of the Dragon ball bearing will be even more thoroughly appreciated by the reader when he realizes that in all existing types of single row radio thrust bearings (which include all other types of angular contact bearings manufactured in standard single row widths) thrust load can be carried in one direction only, resulting in a constantly present danger that the bearing may be so mounted that the thrust load does not fall on the heavy side of the ring. A mistake of this kind in mounting would naturally be disastrous and would inevitably result in the summary destruction of the bearing itself and, very likely, of other parts of the mechanism. In regard to the Dragon ball bearing,

SECTIONAL ELEVATION.

however, it will plainly be seen that there is no possibility of such mishap, since the thrust capacity of this bearing is equal in both directions.

In addition to this the bearing is a self-contained unit and does not require a second bearing mounted with its thrust line opposed, in which event the efficiency of the entire installation depends upon the accuracy with which a

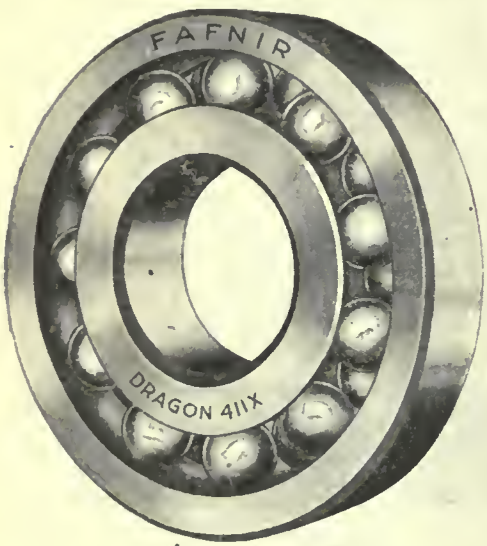


APPLICATIO NOF BALL BEARING TO DRILL SPINDLE.

delicate adjustment is made of the bearings endwise, in order to effect exactly the correct degree of ball contact, involving the elimination of end play without cramping the bearings. This condition, however, applies to all other kinds of angular contact bearings manufactured in standard single row widths and embraces all types of single row radio thrust bearings. These are considerations of primary importance, especially at the present time, since in many plants the men in the assembly departments are not skilled mechanics, and no matter how complete the directions for mounting, mistakes and extremely costly ones, too, will and do occur.

When Applicable

Coming to a discussion of the conditions under which the bearing is particularly applicable, it will be evident from the above statement that here is a ball bearing which, in every instance, is interchangeable with the corresponding standard single row radial bearing, but which, in addition to possessing



THE DRAGON BALL BEARING

equal capacity for carrying radial load, will take heavy end thrust load in either direction. Consequently, it will frequently be found highly advantageous and also economical, both in space and money, to install a ball bearing where hitherto it would have been customary to employ a single row radial bearing and a thrust bearing. For example, under conditions of service involving both radial load and heavy thrust load in either direction at extremely high speeds of rotation, the bearing will be found far more efficient than the combination of radial and thrust bearings. This is due to the fact that the effectiveness of a thrust ball bearing at very high speeds is seriously affected by the tendency of centrifugal force to cause each ball to travel on a tangent and leave the races. On the other hand, centrifugal force actually increases the efficiency of the Dragon type, since it causes the balls to be seated more firmly in the outer races, which tends to increase the thrust carrying capacity of the bearing. Moreover, at this juncture, it should not be overlooked that this bearing may also be utilized in place of an ordinary two-row angular contact ball bearing, performing the same work but occupying less space and being less expensive to buy.

Examples of Installations

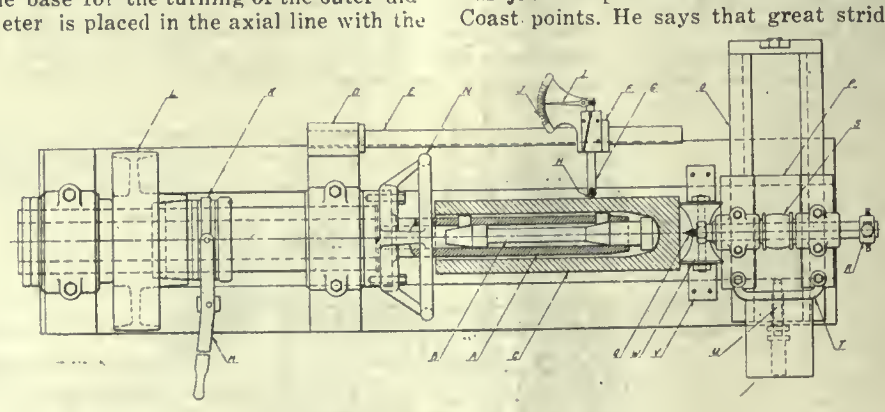
An application which is characteristic of the type of installation for which the Dragon ball bearing is exceptionally useful and efficient is to be had in a worm shaft mounting, a typical example of which is contained in the accompanying illustration. Here the bearing carries the radial load at one end of the shaft and, in addition, takes the heavy end thrust load involved in the transmission of power through the gears. Finally, it will be noted that a Dragon bearing is mounted to carry the drill thrust of the high speed drill spindle shown in the accompanying cut.

SHELL CENTERING MACHINE

ECCENTRICITY in the walls of shell forgings has always been a serious factor in the production of munitions. It is the exception rather than the rule to obtain a shell forging with absolutely uniform walls. The variation in the thickness between the thin and the thick side is sometimes so great that nothing can be done to utilize the forging. Fortunately the percentage of shells now rejected for this defect is considerably smaller than when this industry was in the incipient stages, the work now turned out by the presses being more accurate and the equipment more reliable. However, it is still practically impossible to produce shell forgings with concentric walls, so that care must be exercised in the primary centering operations to insure the turning of the shells to the specified diameter.

Owing to the bore of the shell offering the greatest obstacles to accurate machining it is invariably the practice to do the initial gauging from the interior surfaces. Whenever possible the center in the base for the turning of the outer diameter is placed in the axial line with the forged bore. This naturally throws any eccentricity upon the exterior surface. Various methods have been devised to determine whether this eccentricity is greater than permissible, the general practice being to gauge the wall before placing the shell on the centering arbor. The factor of time, however, is the chief consideration in the adoption of any device for this purpose.

The drawing herewith illustrates a machine produced by the Victoria Foundry Co. for the base centering on the 6-inch shells. Several features are incorporated in the design that tends to economy and rapidity of operation. The arbor A is secured to the nose of the spindle which is hollow for the use of a draw rod when same is required. The operating bolt B is so designed that the pressure on the end is sufficient to maintain the jaws against the bore of the shell while the center is being drilled. An extension D to the front bearing carries the small shaft E upon which slides the casting F, and at right angles to the traverse of F is located the sliding rod G, the front end carrying the small wheel H and the back end carrying a small pin for operating the pointer I, the needle of this finger indicating the eccentricity (magnified) on the graduated quadrant J. This is accomplished by the turning of the hand wheel N., the roller H bearing against the shell and the indicator showing the eccentricity of the forging. When the machine is in operation the gauging device can be swung clear of the shell. The spindle is revolved by means of the clutch operating in the loose pulley L On the right end of the lathe bed is the slide O that carries the saddle P upon which is mounted the centering spindle that carries the center Q. the forward motion of the center being obtained by the movement of the handle R: the lever o fthis is not shown. The carriage can be moved to the back of the slide by means of the handle T so that the shell may be removed from the arbor. To prevent the weight of the shell from resting on the end of the arbor when removing it from position, a roller W is provided, this roller being supported on a shaft resting in brackets placed on the bed of the machine.



SHELL CENTERING MACHINE

Victoria.—W. P. Hinton, vice-president and general manager of the G.T.P., has just completed a tour of the Pacific Coast points. He says that great strides have been made in shipbuilding in the coast since his last trip, and predicts that the renewal of the wooden shipbuilding industry at Victoria will be the making of the port industrially and commercially.

Tantiron; An Acid Resisting Ferro-Silicon Alloy

Acid-resisting Irons of Great Use in Industry—Replace Far More Expensive Metals and Give Equal or Better Service

THE manufacturing chemist and metallurgist are greatly restricted by the limitations of applicability of their apparatus. In many processes, the difficulty is not so much to obtain the raw materials as to find furnaces, containers, pipes, &c., that will bear the chemical and physical stress of the reactions, and to avoid the contamination of the products by the substances with which the reactions bring them into contact. For these reasons many a promising process never gets beyond the laboratory stage; hence, also the cry for substitutes of rare, expensive materials, as well as the natural distrust of them. The enhanced activity of certain chemical industries has much increased the demana for refractory materials and acid-resisting alloys. Experiments with acid-resisting iron alloys are not new, of course. Wollaston made a silicon-iron, and he may not have been the first. Engineers and electricians found silicon-iron very useful for special purposes, and many attempts were made to construct chemical plant of silicon-iron and other iron alloys. Tungsten, chromium and nickel were tried. But foundrymen seemed to be unable to make vessels even of moderate dimensions of such materials, and it was not till 1912 that an acid-resisting iron alloy of sufficient uniformity and strength for the engineer to deal with was put on the market, states "Engineering."

It was the tantiron of Mr. R. N. Lennox, made by the Lennox Foundry Company, of Glenville Grove, New Cross, S. E. Since then silicon-iron and other non-corrosive iron alloys have been brought out by several firms. Both the "duriron" of the Duriron Castings Company, of Drayton, Ohio, and the "ironac," of the

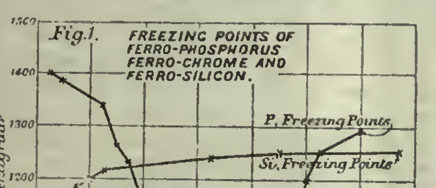


FIG. 1

Houghton Company, of London, are silicon-irons, like the mètillures of A. Jouve, one of the first in this field, and the Italian eleanites, which contain about 2 per cent. of nickel. The American rights for tantiron were, in 1913, taken over by the Bethlehem Foundry and Machine Company, Pennsylvania. "Ferrochrome" is supplied by the Electrometallurgical Company of Niagara Falls; the "feralun" is likewise an American product, and German activity in the field will not have ceased during the war; in addition to "neutraleisen" there are ferrochromes and ferro borons.

That Mr. Robert N. Lennox should have taken up the manufacture of apparatus for the concentration of strong acids was only natural. His father had made sulphuric acid in Glasgow in the days when heavy investments in platinum plant were indispensable for that purpose. When Mr. Lennox started a foundry on his own account, he had for a good many years conducted experimental engineering works of his own, and had, as assistant in the Royal Institution for nearly 25 years, taken his share in Sir James Dewar's low-temperature and high-pressure researches and in the manifold other investigations which are being carried on in the Royal Institution. Extensive well-equipped laboratories are a noteworthy feature of his works.

Properties

Tantiron—a fancy name—is a silicon-iron, containing about 15 per cent. of silicon. In appearance it is a silvery-white close-grained cast-iron, and has the general properties of a machinable cast-iron. One special brand of tantiron is very hard, and not machinable; another quality resists hydrochloric acid which the others do not. It melts at about 1,200 deg. C., can be cast, ground with carborundum, cut with the saw, drilled, screw-cut and tapped, &c. So far as chemical and mechanical corrosion is concerned, it is a superior iron and is used for cast vessels or in the shape of linings for those of steel or iron. It does not rust, except at the skin, and the rust is removed by pickling in diluted sulphuric acid or by grinding. The tantiron itself is not—or practically not—attacked by sulphuric, nitric, or acetic acids, concentrated or diluted, boiling or cold, and indeed not by most chemicals. One kind already mentioned—a more recent invention—also resists hydrochloric acid equally well. Carbonic

FIG. 2

acid attacks it slightly, but the corrosion is only about one-thousandth that of cast-iron. Alkalis corrode it about as much as they do cast-iron; chlorates and perchlorates do not corrode it, and it will resist chlorine gas up to a temperature of 105 deg. C. But sulphur dioxide corrodes tantiron badly. In view of this latter fact, the suitability of tantiron pans and basins for the concentration of sulphuric acid is rather surprising Large pans have been in use, however, we are informed, since 1912, and some 25,000 basins are actually in use in sulphuric acid works. There is some slight corrosion, of course, and there are breakages, partly due to the material, partly to improper treatment by unskilled labour, which causes many small and large accidents in these days of rapid plant erection and high-pressure activity. The maintenance cost of pans and basins is about 2½d. or 3d. per ton of acid concentrated. After boiling 100 grams of the alloy for 17 hours, 10 per cent. sulphuric acid was found to have dissolved 0.13 gram of tantiron, 25 per cent. nitric acid, 0.25 gram, and 30 per cent. hydrochloric acid, .16 gram.

Limitations

The terms "non-corrodible and acid-resisting iron," are misleading, as all such general terms are. Every chemist knows that he must not allow metals to glow in his platinum crucible, as they would form fusible platinum alloys, and that caustic alkalis and certain alkali salts, and even the sooty flame of the gas burner, will ruin his crucible. Tantiron also has its peculiar weaknesses. It resists hot sulphuric acid much better than cold acid ,and many instances of attack are so far inexplicable. In one case, a tantiron tower containing vapours from boiling sulphuric acid showed defects in the top sections, without any attacks on the bottom sections. The top sections were replaced several times; the bottom sections, which had

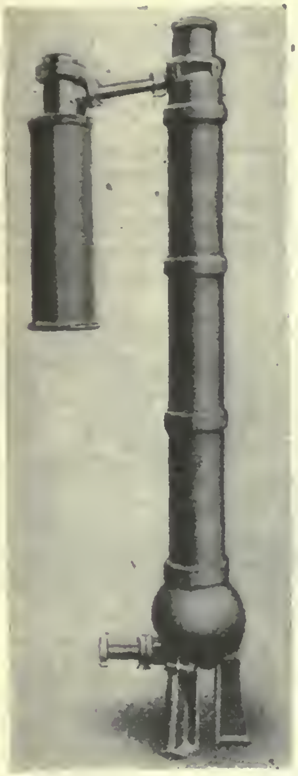

FIG. 3—DENITRATING TOWER

been in use for eighteen months, were taken out and inserted in the top, when they were attacked within a fortnight; yet temperature determinations at different points of the tower never showed differences exceeding 5 deg. C. In other cases, sulphuric acid, on being carefully freed from arsenic by sulphuretted hydrogen, attacked the tantiron nearly three times as quickly as the original acid. But the amount of attack is, of course, exceedingly small. A tantiron vessel weighing 4,950 grams, had 600 tons of sulphuric acid passed through it during concentration with a total loss of weight of 12 gram. The attack is mainly on the surface of the skin, which should, therefore, be removed when corrosion tests are conducted.

Though the iron carbide seems chiefly to be attacked, the corrosion is, apparently, uniform; under the microscope, acid-corroded tantiron keeps its smooth surface, while cast-iron shows irregular corrosion. Mr. Lennox prefers to have no carbon in the iron at all. His raw materials are cast-iron, scrap, and old tantiron, and further ferro-silicon. The latter is obtained with about 12 per cent. silicon from Middlesbrough, and in a 50 per cent. grade from Norway. The average composition of tantiron is in per cent.: silicon, 14 per cent. or 15 per cent.; total, carbon, from 0.20 per cent. to 0.60 per cent.; manganese, 0.25 per cent. to 0.35 per cent.; phosphorus, 0.16 per cent. to 0.20 per cent.; sulphur, under 0.05 per cent. The three kinds mentioned, machinable tantiron, hard tantiron and tantiron for hydrochloric acid, differ little in composition, but the small fractions of additional constituents are very important. To study their influence, ingots are poured from furnace charges of 1 ton, to which additions are made in very small increments; the ingots are then tested chemically and mechanically. The sulphur and manganese, in their percentages, seem to be of no consequence. The phosphorus is deleterious, mainly probably because it is not uniformly distributed, but concentrated in spots. As phosphorus is added to iron, the freezing point is first lowered, and then, when 10 per cent. of phosphorus is exceeded, rises again,, but the cooling curves are not regular, whilst the freezing point curves of silicon-iron and chrome-iron show a very slow, but steady rise with increasing percentages of those elements. (See Fig. 1.) Impact tests are made on ¾-in. square bars, which are not notched; they break, e.g., under stresses of from 8 ft.-lb. to 10 ft.-lb., against 12 ft.-lb. to 14 ft.-lb. in the case of cast-iron. On the whole, the strength of tantiron is about 25 per cent. smaller than that of cast-iron. The following is a summary of the comparative properties of tantiron and cast-iron (the latter figures in brackets): Density 6.8 to 7.0 (7.3); tensile strength, 6 to 7 (9 to 10) tons per sq. in.; transverse strength, bars of 12 in. by 1 in, 1,600 lb. (2,500 lb.); crushing strength per inch cube, 34 (40 tons); melting point, 1,200 (1,150) deg. C.; hardness, 1.6 (1); heat conductivity, 8 (10); electrical resistance,

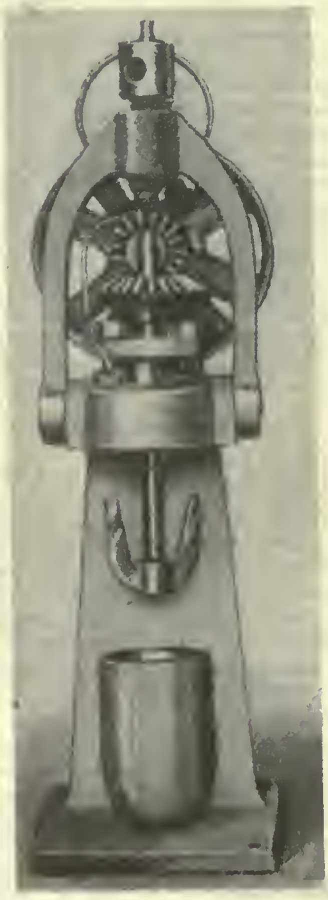

FIG. 4—AUTOCLAVE CUP OPEN ON STAND

10 (8); resistance to corrosion, 1,000 (1); contraction allowance in casting, 3-16 (⅛) in. per ft. As regards other properties, also of other materials, the comparative order for iron, tantiron, lead,

FIG. 5—AUTOCLAVE CUP CLOSED

quartz, stoneware is: Transmission of heat, 230, 215, 115, 28, 20; hardness, 24, 35, 1, 52, 32; density, 7.3, 7, 11.3, 2.6, 2.0; melting point, 1,150, 1,200, 335, 1,900, 1,800 deg. C.

Limits of Corrosion

With respect to corrosion by chemicals, there is generally a first attack, followed by relative immunity under continued exposure. The following figures indicate the percentage losses of tantiron after boiling for 24, 48, 72 hours; the greater action during the first 24 hours is largely due to the already-mentioned skin effect, the outer surface having been changed by contact with the sand in which the tantiron is cast; this skin is removed in the foundry, as we stated.

	First 24 hrs.	Second 24 hrs.	Third 24 hrs.
Sulphuric acid, 98 per cent.	.10	.02	.02

To meet the peculiarities of the material, it is desirable that designers of parts to be made in tantiron should bear the following rules in mind: large flat surfaces should be avoided, corners be

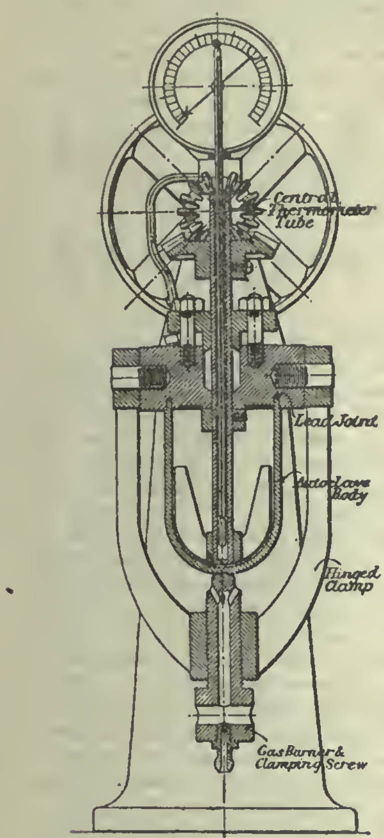

FIG. 6—SECTION THROUGH AUTOCLAVE

rounded; slots be used by preference to bolt holes; facing strips be narrow and of ample height; the effects of expansion and contraction should be well-considered; coring and moulding be made easy, by preference without the use of chaplets to support cores. Among the chief products now made wholly or partly of tantiron, are: acid pans, basins, stills, bleachers, denitrating towers, autoclaves, condensers, pumps, stop cocks, valves, pipes and fittings, electrodes, &c. Frequently a tantiron lining will suffice to prevent either chemical or mechanical erosion. The largest tantiron casting so far constructed weighed 7½ tons.

Moulding

The greatest care is bestowed upon clean moulding, which is mostly done by women, and use is made of rotating strickles in preparing the moulds for parts of circular section. For lining pipes with tantiron, the pipe must be suspended vertically by a flange with the core in proper position, the pipe to be lined being weighted below; if the liquid tantiron were poured into a horizontal pipe, the pipe would curve. This practice is generally adopted for lining iron or steel, wherever possible, and the part to be lined is well dried, but not pre-heated. The adhesion between the iron and the tantiron is said to be good, fusion taking place between the surfaces; the adhesion is tested with the aid of paraffin oil. The lining may have a thickness from ¼ in. up to 1¼ in. and more. The subsequent finishing of the product is largely done with the aid of carborundum wheels and grinders. It is rather curious that the fine tantiron particles torn off by the tools do not spark; there is only a glow. Drills, saws and planers are also used.

The basins for the heating and concentration of sulphuric are mostly of the plain porcelain dish style, but are provided both with a lip and an arc-shaped baffle (not shown); they are supplied also in the Webb and Dyson styles (Fig. 2). The basins are arranged in cascade, so that the hot acid drips from the lips of one basin into the one next below, and the baffle prevents the acid from streaming right over the basins to the lip. Provision for more efficient circulation and stirring of the acid in the basin is made in the "Mackenzie field tube evaporator basins," also supplied by Mr. Lennox; this style has calix shape, being a tube opening out into a basin; a "field" tube fits concentrically into the cylindrical portion and promotes active circulation. Other basins are provided with covers and necks, and made corrugated, and they serve generally also for the concentration of corrosive liquids, such as zinc chloride, lead nitrate, &c.

Concentration of Nitric Acid

The concentration of nitric acid requires more varied apparatus, which have successfully been made of stoneware in the past few decades. When the war broke out, the stoneware works of this country were not able to deal with the demands, and tantiron vessels, which can be made in a few days, whilst good stoneware requires months, were largely adopted. Valentiner plants, comprising a still, condenser and coils, built up of pipes and return bends flanged together, all of tantiron, are now made. The denitrating tower illustrated in Fig. 3 is an interesting novelty. The spent acid of nitroglycerin works consists of diluted sulphuric acid, which has to be concentrated again, and some nitric acid, which is to be regained by distillation. There may also be small globules of oily nitroglycerin which might coalesce if the evaporation were carried on in pans. The tower, 15 ft. high, is built up of socket pipes, 14 in. diameter, and is packed with quartz fragments; the acid enters at the top and steam at the bottom, and the nitric acid and vapours condense in the cylinder by the side of the tower. Nitric-acid stills are also used for the distillation of acetic acid. The autoclaves for making ammonium nitrate from cyanamide at a temperature of 120 deg. C. and a pressure of about 2 atmospheres, resemble one

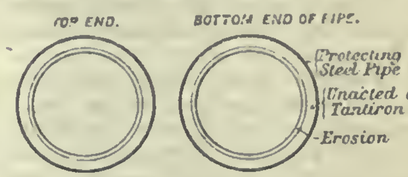

FIG. 7—EROSION OF TANTIRON PIPES IN SERVICE

style of nitric-acid retorts. The outer vessel is a jacket of cast iron, the inner vessel of tantiron forms the saturator; the height is 8½ ft., and the diameter 4½ ft., e.g.

The autoclave illustrated in Figs. 4, 5 and 6 is a clever compact laboratory apparatus, whose utility and handiness will appeal to every chemist. The ordinary autoclave has to be screwed up tightly and unscrewed again each time. In this Lennox autoclave the parts are clamped and unclamped by the use of one spanner, and everything, crucible or cup, stirrer, pressure gauge, burner, is ready for use. In Fig. 4, the cup is seen on its stand open, and the stirrup clamp is turned up. When the cup of tantiron is lifted, and the clamp turned down, the cup is pressed against the lead joint in the cover (Figs. 5 and 6), and the autoclave is sealed; the bolt passing through the clamp, by means of which the autoclave is tightened up, also serves as the gas burner, and the axial stem of the stirrer is hollow to receive a thermometer; the stirrer is actuated by an electric motor.

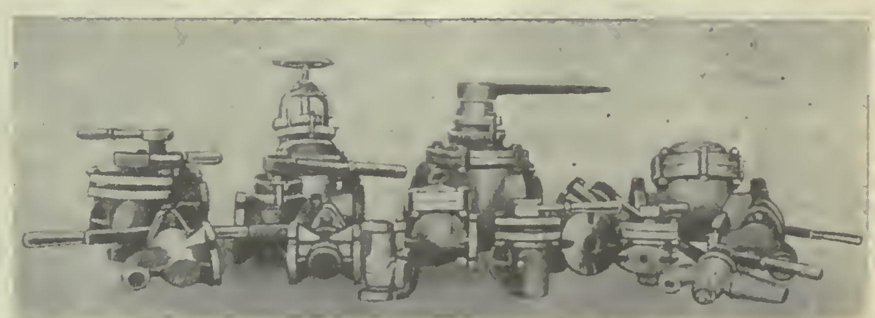

FIG. 8—ACID PROOF VALVES AND FITTINGS

Acid eggs, apparatus for forcing up corrosive liquids with the aid of compressed air, are made of two tantiron cups, joined by their top flanges so as to form a horisontal cylinder with spherical ends and one common flange on the vertical middle plane; they are provided with acid inlet and outlet valves and an air pipe, and are supplied in large sizes. The pumps of the works, reciprocating and centrifugal, do not differ much in appearance from ordinary pumps; the barrels and impellers and pipes are made of tantiron or lined with it. As these parts of hard tantiron cannot be machined or repaired, it is recommended to keep spare parts ready for cases of accident. Centrifugal pumps are supplied for lifting 6,000 gals. of acid or corrosive mine water, &c., per hour, against a head of 50 ft., running at 1,600 r.p.m. Slime pumps, e.g., for conveying the crushed quartz in gold mines, are likewise made of tantiron, to obviate the heavy erosion of the pipes by the gritty quartz particles. For the same reason, tantiron-lined steel pipes are used in the Rand mines, South Africa, for the sand-filling plant When the pillars left in the galleries below are to be removed, the galleries have to be refilled with the finely crushed quartz from the vast white waste mounds which form a conspicuous feature of the district. The spoil is flushed down the pipes with water. The first pipes used, steel pipes, were ruined by 6,000 tons of sand; porcelain-lined pipes were then tried, which could stand up to 50,000 tons; the tantiron pipes, introduced four years ago, are still doing duty, and their life capacity is estimated at 500,000 tons. The 500 ft. of 5-in. pipes put in were delivered in sections of 7 ft. Fig. 7 illustrates the erosion they had undergone by the passage of 106,000 tons of quartz sand under a head of 500 ft. In each case the outer ring represents the steel pipe, the second, intermediate ring, the tantiron remaining intact, and the inner ring the eroded thickness. The erosion is greater at the top, where the sand strikes the pipe than at the bottom, and is not the same in all sections, probably owing to peculiarities of their positions. Similarly-lined steel pipes and tantiron pipes, up to 2 ft. in diam., are in use for ash ejectors, especially on board ship, where heavy erosion and corrosion by the caustic ashes and the sea water have to be guarded against.

In stop cocks and valves of tantiron corrosion by acid sodium bisulphate (the acid cake residue of the distillation of nitric acid from salt and sulphuric acid), erosion by grit, rusting and sticking are the chief sources of trouble to be met. Here, again, tantiron competes with lead and stoneware, and its advantages lie in greater strength and indifference to high temperatures and frost. Fig. 8 shows types of cocks up to 4 in. in internal diam.; a groove is made in the centre of the cock and charged with a greasy preparation of ceresin, vaseline, black lead, and asbestos, which is pressed into the groove by means of a screw. A great variety of cocks, valves, T-pieces, straight and bent socketed pipes, provided with threads, are made in tantiron.

Specialties

Of other specialties, we mention the corrosive-vapour drying and baking ovens, the flat doors and walls of which are lined with sheets of tantiron, which are screwed on. Tantiron can be rolled at about 700 deg. C., but is brittle then. Another specialty is the tantiron electrode for cyanide baths (silver and gold), and also copper baths, &c., replacing iron and other alloy electrodes, which are not insoluble, and very objectionable on this account, or more expensive than tantiron. For the same reason, steel-mixing mills for the manufacture of manganates, the balls and stirrers of other mills, and many apparatus used in the acid and dye and other chemical industries, are made of tantiron.

Foundry work had been carried on in the buildings which Mr. Lennox now occupies for over 100 years. There are 2½ acres under roof, and about 200 people, including 50 women, are now employed. The work of the women, who have all been trained at the works, gives complete satisfaction; excepting in the pouring department, in which men alone are employed, they work in all the departments, in the laboratories, moulding pits and machine shops, as well as in the office, but are under the special control of a lady on the staff, who also looks after their little privileges as to tea and rest intervals, their starting work 10 minutes after the men, and leaving before them, &c. When husband and wife are both in the works, they are not attached to the same department.

Like every manufactured article, tantiron is constantly being improved, and does not claim to have reached final perfection. Acid-resisting materials must possess various properties which are not easily combined, and possibly not capable of combination. A compromise has to be accepted.

FLINT AND TINDER

By A. L. HAAS

In the account given of the flint knapping industry of Brandon, Suffolk, England, on page 225, August issue, there is a serious misconception.

The industry survived not upon commercial merit so much as the production of spurious pre-historic flint implements. Nearly every museum displaying flint arrow heads and other products of Neolitric man shows also spurious modern specimens of Brandon handiwork.

While matches are short over here at present they are not unobtainable and the writer has yet to learn that the flint and tinder of our ancestors is being used. The misconception evident is that the so-called flint in the mechanical lighter, whether tinder or petrol, is knapped flint of natural origin.

The substance used is an artificial product, a side issue in the making of the substances with which incandescent gas mantles are impregnated.

Actually, it is ferro-cerium and is in every respect superior to the natural flint stone in its sparking quality in conjunction wth hardened steel. The flint knapper of Brandon will doubtless still find a market for his wares. the credulous are numerous and short of the advice of an expert. It is well to be wary of pre-historic flint implements offered in many places to the tourist in search of trophies. Actually there is reason to believe that the only flints made to-day from natural stone are for export to where the heathen in his darkness bows down to wood and stone, while the lucifer match has penetrated almost the entire globe. The flint lock musket was the last real use to which natural flints prepared by knapping were put and that is many scores of years ago.

ST. LAWRENCE NAVIGATION EXTENSIONS

By D. I.

During the past decade, interesting and, as results have shown, important experiments have been carried out by the Quebec Board of Trade and others on behalf of the Canadian Government, with a view to ascertaining to what extent the navigation season of the St. Lawrence, which officially opens about the beginning of May and closes towards the end of November, is capable of prolongation. Those who took part in the inquiry are, definitely of opinion that ships may run between Quebec and the sea at all times of the year, and the Dominion Marine Department is now being urged to provide the additional safeguards that are considered necessary, such as sheltered storm centres, buoys and wireless stations. By this means it is believed regular cargo steamship services could be established between Quebec and the United Kingdom all year round. The employment of powerful ice-breakers would also be essential in lower reaches of the river. A board of marine underwriters for Canada on the lines of Lloyd's is about established at Montreal. It will among other things provide for a system of correspondents all over the world and supply early and accurate information of wrecks and casualties with special reference, however, to conditions on the St. Lawrence.

VALUE OF SCRAP IRON

By T. H.

In view of the increasing demand from the steel mills of the country for scrap iron, which demand is said to far exceed the supply, an appeal has been made for a special effort to save all such material. Before the trunk railways of the country were taken over by the Government, the railways were the most important contributors to material of this class used at mills. In many instances it could be delivered cheaply by the railroads themselves, and they have good facilities for its collection. It is said that if all the available iron and steel scrap in the country were marketed there would be no shortage of steel at the mills. Its collection has apparently been somewhat neglected since the Government assumed contro of the railroads, but there is no logical reason why such economy should not be practised under Government administration.

Cheap Labor Was Not Very Cheap in This Case

Locating a Factory in a Small Town to Secure Cheap Land and Low Labor Cost—Many Other Things Entered to Make It Certain That the Cheap Location Was a Very Expensive One

By T. H. FENNER, Associate Editor.

WHEN a manufacturing company, with a well established business in one section of the country, or in another country, wishes for the purpose of extending their business to establish a branch establishment in some district far removed from the head office, they often fall into some grave mistakes in their choice of a location.

A great many firms are content to locate in some well-defined manufacturing district in the midst of a considerable population and in so doing accept the accompanying penalties of high land prices, high taxes, and a wage scale governed by prevailing conditions. To offset these conditions, they have the advantages usually associated with an established industrial locality, these being plentiful rail and water shipping facilities, ample labor supply, and a large stock of general merchandise such as is always required in a manufacturing plant immediately available through the medium of numbers of competing supply houses close at hand. If any particular piece of material for a hurry up repair is required it is usually merely a matter of a telephone message to one or several warehouses in the immediate neighborhood to secure the required article in short time. Being in the centre of things, as it were, it is an easy matter for the purchasing agent to keep in touch with the various markets and the staff generally through the usual daily meetings and intercourse with others in the same line are kept up-to-date and on their toes. The labor turnover will be governed by the conditions prevailing in the factory, but whether it is large or small, the supply will be always on hand. This may not be true in abnormal times such as the last four years, but it is correct in normal times.

Other Ways of Locating

There are other concerns who send their representatives abroad through the highways and byways of the land seeking for some sort of a manufacturing Eden. They are looking for a spot which shall offer all the ideal conditions for an industry without a drawback. They want a situation on the main lines of three or four railways with water transportation also convenient, the town to donate the land for the building, exempt them from taxation for any period not exceeding 99 years, guarantee cheap labor, and instal a fire station at the front gate to reduce the company's insurance rates. Needless to say, this location has never yet been found and probably never will. However, there are many small rural municipalities who hold out inducements that appear to make the planting of an industry in their midst a good thing for the industry. In many cases it turns out all right, in others it does not. The usual drawing cards are those already mentioned, that is, low-priced land, exemption from taxation, and cheap labor. These conditions coupled with shipping facilities are big inducements to any firm but they should not be the deciding factors.

The Case of Two Shops

There are several conditions connected with a location which though not very evident when a location is being decided on are very evident after the factory is built. The writer has in mind two concrete examples which will illustrate what is meant. Though both located in the same place, they afford two distinct examples. The town in question is in a country district, but only 30 miles from a large manufacturing centre. One of the factories employs nearly all female help, while the other is dependent chiefly on male labor. Both firms received the usual inducements to locate and large sums were expended in building thoroughly up-to-date factories, well equipped both for production and the comfort of the employees.

The first factory had been located in the neighboring manufacturing town and the necessity of extending the plant had determined the executive to move away from the city. The whole of the foremen and executive staff, also the majority of the clerical staff, as well as some of the older hands, were moved out at the firm's expense to the new habitat, their personal effects, furniture, etc., being included. A large portion of the machinery was also moved, and it can be safely said that the expense of the moving of material, etc., would have gone some distance towards the paying of the difference in land values between the outskirts of the city and the rural district selected. In any case, the moving was finally accomplished and the factory started up. Right away the labor problem obtruded itself. Labor was certainly cheap in so far as the actual money paid out was concerned, but taking into account the return received on the money, labor was dear. The population the labor was drawn from was chiefly agricultural and densely ignorant of mechanics. Furthermore, never having been used to work regular hours for regular wages, they were inclined after receiving a week's pay to lay off until the money was spent when they would work for another week. This, of course, did not apply to every worker, but to enough of them to make their presence, or rather absence, felt. Some of the foremen who had moved out from the city became dissatisfied with the simple life and went back to the bright lights. Their leaving opened up another trouble. To induce the right kind of man to come out he had to be paid about 10% more than he would have received in the city. The company would naturally prefer to have married men take positions with them as they would be likely to stay. The right kind of man would make enquiries round about educational facilities for his children and finding these practically non-existent would decide against coming.

And More Yet to Come

This was all very discouraging, but there was more to come. Some of the men who were capable and intelligent and learned to be fair operators soon discovered they could get work in the city at better wages and off they would go. The result of all these conditions is that a factory equipped with very expensive machinery and extensive buildings for large production has never approached nearer than 30% of the capacity designed for, and furthermore its cost of production is higher than that of any factory owned by the same firm notwithstanding the lower wages paid.

The experience of the second factory compares closely with this. They were a United States firm establishing a Canadian factory with entirely new equipments. The executive staff only was sent from the States, the intention being to train up foremen locally. The same trouble was experienced. The local material could not respond to the opportunities and men had to be sent from the States. These men came more or less under compulsion and with a feeling that they were being side tracked, a feeling not without justification. Any man capable of filling a responsible position who is placed in one of these outlying factories knows that he is liable to stay there indefinitely as the difficulty of getting the right kind of man to move from a factory situated in a more

(Continued on page 487)

FROM THE MEN WHO PRODUCE

Methods, Machining Devices, Systems and Suggestions From Shop And Drafting Room

MANUFACTURING THE HILL HOLD BACK DOG

By ROBERT MAWSON

EVERY machinist is familiar with the method used of holding a piece of work which is only carried on one center, that in the head stock, and the outer end of the work supported in the steady rest.

The practice followed is to fasten the dog, which is attached to the work, by means of rope or similar medium to the face plate. For the fastening operation the face plate is screwed back a distance so that after the rope has been tied the action of screwing the face plate home tends to tighten the hold which the rope has on the dog and work.

At best this method is slow and unsatisfactory. Often when leather straps are used for the fastening means they stretch and the result is a drive which is not positive.

To overcome these difficulties the Ready Tool Co., Bridgeport, Conn., have developed a mechanical hold-back dog which can be set up easily and quickly. One of these set up in position is shown in Fig. 1.

It will be seen that the work is gripped by male and female vees, adjustment being provided with set screws A, one on each side. A bolt B passes through each driver and through one of the face plate slots. At the rear of the face plate springs are placed on the bolt B, which afford the flexibility of lacing but superior in that a spring has no permanent stretch or give.

The bolts are adjustable with the knurled collar shown so that they may be set to cause the work to run true. The outer end of the work is supported in a steady rest in the usual manner.

The jig used when drilling the male driver is shown in Fig. 2. The forging is located by two angular blocks A and forced back against the rear wall of the jig with the screw B operated by the handle shown. Two holes are then drilled, one in each boss, the drill being guided through bushings as shown.

A similar jig is used when drilling the female driver, shown in Fig. 3; the only

FIG. 1—HOLD BACK DOG SET UP ON LATHE

FIG. 2—DRILLING THE MAIN DRIVER

FIG. 3—DRILLING THE FEMALE DRIVER

FIG. 4—MILLING THE SLOT

difference is that a raised block which fits in the depression of the forging is used as the locating medium.

The forging is forced and held back with a screw of a similar design to the tool last noted, two holes are now drilled, afterwards being tapped to suit the set screws.

An interesting feature of the drill jigs shown in Fig. 2 and 3 is the method of holding the piece.

This is by means of a nut riveted to the end of a threaded rod. At the outer end of the rod is attached a crank, the turning of which holds or releases the part according to its rotation.

This medium of a crank for operating the holding device is both quick and positive and could be copied to advantage on the design of many jigs and fixtures.

In Fig. 4 is shown the method used to machine the slot in the drivers, male and female.

The piece is located by two pins A, which fit in the drilled holes. Nuts, as shown, hold the forging securely.

The milling machine table is then fed to stop against the revolving cutter B, which finishes the inside of the slot and also faces it. The table is afterwards fed up or down until the full length of the slot has been machined.

The rest of the elements used on the dog are simple lathe operations and need no detailed description.

The forgings are afterwards polished and hardened when they are ready for assembling into complete hold-back dogs to the form already shown.

GAS FIRED BOILERS

By M. M.

It may usually be taken for granted that where power is to be generated from gas fuel it is more advantageous to instal an internal combustion engine, but many cases arise in which, for considerations overriding that of thermal efficiency it is desirable to burn the gas under boilers serving a steam engine, and in such cases it is important that the boilers should be well adapted to the special requirements of gaseous fuel combustion. In discussing the suitability of various types of boiler to gas firing, there is a disadvantage in the Lancashire boiler when gas-fired in any of the usual ways. The fall of temperature in the gases from one end of the flues to the other is not sufficient to set up good circulation of the water as is done by the intense local heat of the fire when the boiler is coal-fired. Boilers of the Lancashire type intended for gas firing would be better with three or four flues, instead of the usual two, as that would not only give a larger heating surface, but aso allow of smaller volumes of gas being burned in each flue, which would enable combustion to proceed with a smaller excess of air. Carrying this line of argument a little further and keeping in mind the advantages of the flue boiler over the water-tube boiler when using feed water of doubtful quality, the best results would probably be obtained by having a boiler with a considerable number of smaller tubes, forcing the gas to burn at the highest possible temperature in each, with no obstruction in the tubes and no mechanical suction. Such a boiler, properly insulated, would give at least as good results as the best water tube boiler, provided that the correct ratio of boiler length to flue diameter was ascertained. This could be worked out at a comparatively small cost by experimenting on pipes of different diameter and length immersed in a water tank. Wherever high-pressure boilers are to be installed there is little doubt that water-tube boilers will be chosen if the available feed water is soft enough, or can be suitably treated. It is important that sufficient combustion space should be provided for the huge volumes of gas to be burned, so that the gas may be fully burned before passing through the tubes, but external combustion chambers should be avoided as causing unnecessary losses by radiation and conduction of heat and because the highest temperature is not attained in the immediate vicinity of the tubes. The two great drawbacks to the gas-firing of boilers as against their firing with coal are the low rate of evaporation per square foot of heating surface, which with the best water tube boilers is seldom more than 5 ½ lbs to 6 lb of steam per hour, and the relatively low efficiency obtainable. The best boiler up to the present is unquestionably a water-tube boiler which is arranged so that the gas can be fully burned before passing through the tubes and where the gas stream is kept at right angles to the line of the tubes by careful baffling, and to get higher outputs from such a boiler per square foot of heating surface only requires a more rapid combustion of the gas, with more intense flame temperature. Because of the low rate of evaporation and low efficiency of gas boilers, the project of gasifying steam coal, recovering the by-products and burning the gas under steam of boilers has not made much headway, as it has been found that steam can be raised more cheaply from the coal direct, even after allowing for all the income derived from the sale of by-products. Even now there are moddern producer plants and boilers on the market which can make gasification and gas-firing a commercial success under suitable conditions, and improvements are to be looked for.

DRESSING TARPAULINS

For temporary protection against rain, tarpaulins are largely used, this causing an annual dressing to be necessary. In arranging for this all necessary repairs should be done, and the sheets should be laid out open and thoroughly brushed and cleaned on one side, being afterwards hung up to dry thoroughly. When dry they should be thoroughly dressed on both sides with one of the various dressings sold for the purpose, or they could be done with one made up as follows:—14 lbs good black paint, 1 lb powdered litharge, 2 pints oak varnish, 1 pint boiled linseed oil and 1 pint thick boiled oil, well ground together and passed through a strainer to secure smoothness. After the first coat has dried, the outside of the sheet should have a second coat, the dressing and drying occupying about three weeks in fine weather.—D. S.

CINDERS

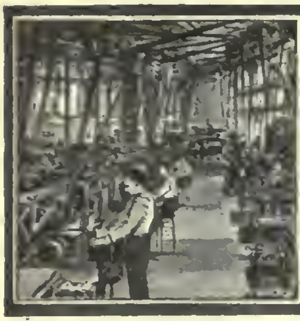
By T. H.

In view of the fuel shortage, present and prospective, particular importance attaches to cinders. According to an estimate made recently 3,745,000 tons of cinders are either tipped or burned in British municipal destructors every year, and this cinder fuel is equivalent to no less than 2,675,000 tons of coal. Some of the more enlightened local authorities utilize the cinders for steam raising purposes, but the comparative fewness of those bodies may be judged by the fact that this economic use absorbs only about one-eighth of the total quantity of cinders collected by the municipalities, thus leaving the equivalent of 2,226,000 tons of coal absolutely thrown away. London is alleged to be one of the worst offenders, but even in the Metropolis there are a few municipalities which, before the era of fuel rationing, had kept a wary eye on the calorific potentialities of the dustbin. The recovery of cinders, now allowed to go to waste, reckoning coal at 26s a ton means an annual saving of £2,894,000, and on the basis of the 1916 output a year's labor of 11,000 miners. Coal rationing will no doubt stimulate private economies, but it may not have occurred to the authorities that the scarcity and dearness of sieves and sifters militates against private effort in this direction.

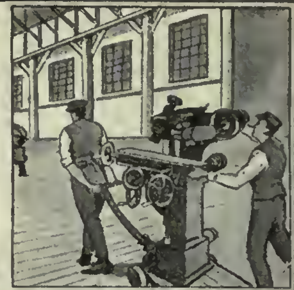
NEW APPRENTICESHIP SCHEME

By R. E.

It is to be hoped that more will be heard of the highly interesting scheme of apprenticeship which is being taken in hand by a big London grocery firm. The the old plan of apprenticeship as interpreted in these days has outworn its usefulness is obvious, but it is equally obvious that something must take its place if our commercial ascendancy is to be maintained. This wise and enterprising firm offers to boys who will engage for three years, working six hours, seven hours and eight hours a day respectively, facilities for education at a continuation school in the first year, at the Grocers' Institute in the second, and at one of the best London business colleges for the third year, the firm paying all expenses, and gives wages of six shillings, twelve shillings and eighteen shillings in the three years. The result of this should be that boys who care to apply will be thoroughly outfitted with a sound commercial education side by side with practical knowledge. If some such plan became general in big cities the whole standard of commercial acquirement would be raised to the benefit of both parties and of the State.



DEVELOPMENTS IN SHOP EQUIPMENT

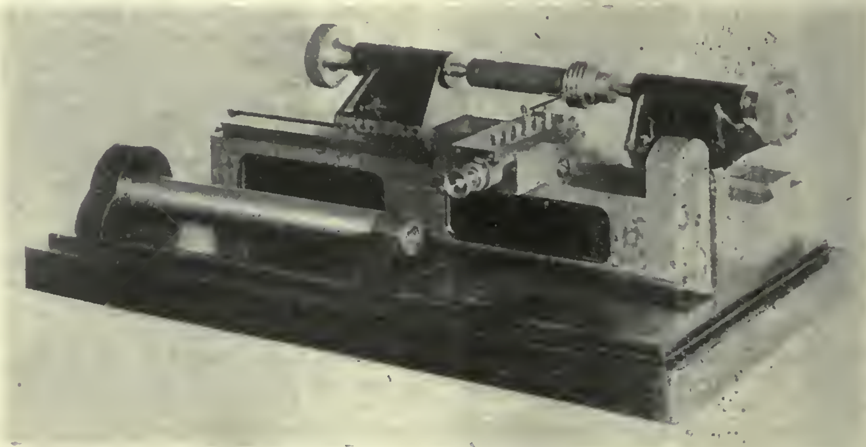


Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.

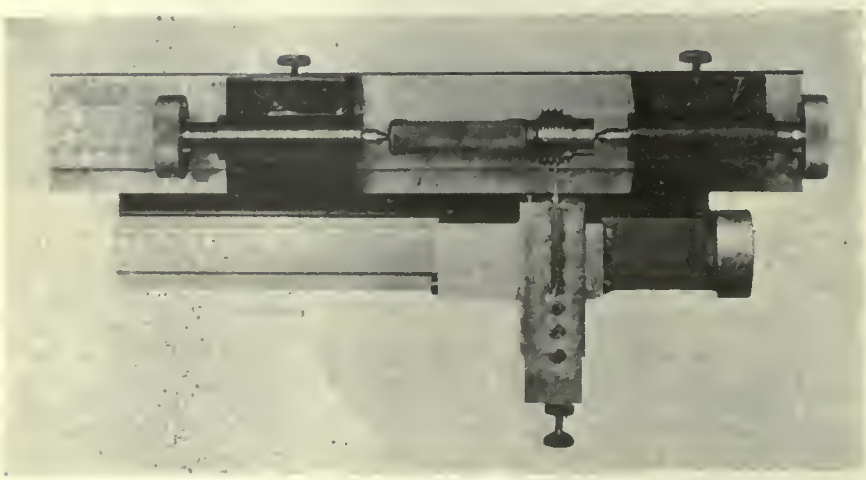
LEAD TESTING MACHINE

This machine was designed with the idea of providing a very rapid and accurate method of determining the error in lead of screw thread gauges and to enable those required to pass upon large quantities of gauges to secure dependable results in minimum time.

It will be noted that the device consists primarily of a cast iron bed machined all over with two parallel dove-tail bearings on the top. Upon the rear and larger bearings are mounted the centers for holding the gauge to be tested and upon the front bearing is fitted the sliding block which carries the indicator slide. Upon this slide is mounted the indicator which is held in place by means of a hardened stud which is clamped in position with a small headless set screw. Both the sliding block and the indicator slide, which has a dove-tail gibbed bearing in block are sufficiently long to afford ample bearing surface and by mounting the indicator in the proper bushing the operator is assured of a full bearing of slide in block when machine is in use.



SHEFFIELD PRECISION INDICATOR.



SHEFFIELD LEAD TESTING MACHINE

The indicator slide is provided with a knurled stop screw with lock nut giving assurance that the indicator ball will record from the same point on the angle of each thread after being set in first thread to be tested.

The Deming precision indicator, also a Sheffield product, which is used to record the amount of error, is an extremely accurate tool and is graduated to read in ten thousandths of an inch and the scale is so arranged that fractional parts of tenths can be very closely estimated. Several sizes of ball points are furnished to enable readings to be taken of any pitch—the finer pitches, of course, requiring the smaller points.

The gauge to be tested is mounted between the centers as shown, the heads bing clampd in desired positions by means of knurled binding screws in rear. A Johannson block is inserted between the contact points to obtain zero reading. One of these contact points is on the sliding block and two in steel plate projecting upward from end of bed. The indicator slide is then pushed toward the gauge until the ball point of the indicator slide comes in proper contact with the angle of first thread to be tested, the stop screw set and locked. The gauge is either turned slightly or adjusted longitudinally by releasing one and advancing the other center by means of the threaded center spindles with knurled heads until the indicator needle reads zero on graduated scale.

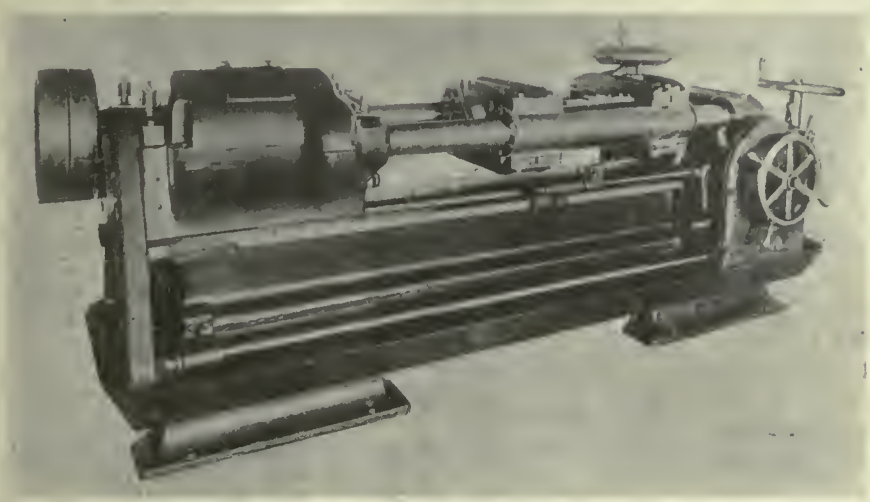
It may be assumed for convenience that the gauge to be measured is 8 pitch; it will be readily seen that it to the initial Johannson block is added another measuring. 125 in. and the slide brought against this combination as before that the indicator needle when point is again brought in contact with thread would still read zero, providing the distance between the two threads is exactly 1-8 in. Should there be an error of .0001 in. or even .00005 in. in lead either way it will be clearly shown on the scale. In the same way that the 1-8 in. block in combination with the one used for the first reading gives the correct lead for the first thread, using the 1-4 in. block would give the lead for two threads or the 1-2 in. block for four threads, etc. Other combinations can be readily made up in this manner for any lead, either English or metric, (the latter by using metric blocks) with no chance of error as the use of a micrometer or screw measuring device of any kind is eliminated. In fact the complete unit may be described as a holding fixture for the work and a measuring system, both as simple and dependable as it is possible to make them.

A machine for such accurate measurements must necessarily be very accurately built and we therefore are extremely careful as to the quality of material and workmanship which enter into its construction. The castings are well seasoned and all alignments are accurate to within a fraction of a tenth. The hardened and ground test bar shown, one of which is furnished with each machine, is provided to enable the user to check the alignment of the two parallel dove-tail bearings on bed to detect any wear which might affect the accuracy of the results obtained.

Either straight or taper gauges can be checked with equal facility and with the aid of a chart furnished accurate measurements may be taken of the form of thread. Gauges and taps 3 5-8 in. in diameter and 10 in. long can be accommodated between centers.

Each machine is furnished with an attractive wooden case and is complete with test bar as shown. Measuring blocks are not included as part of regular equipment.

This machine is manufactured by the Sheffield Machine and Tool Co., Dayton, Ohio.



CYLINDER BOR NG MACHINE

CYLINDER BORING MACHINE

This specialized machine was designed by the Reed-Prentice Co., of Worcester, Mass., for boring the cylinders of Liberty Motors. In the several months that they have been in operation they have accomplished more than was expected of them in the rapid removal of metal accurately. The head unit is very rigid and massive and contains a herring-bone reducton. The bearings are bronze with sight feed oilers. The spindle is hardened and ground on all bearing surfaces. All gearing is entirely guarded with hand hole covers tains a herring-bone gear reduction. The drive is in single pulley 18 in. x 6½ in and gives but one spindle speed. For other classes of work the gearing would have to be redesigned for the work to be performed. The feed is positive gear drive through a single train and is designed for the class of work at hand. In the apron the feed is by worm with approximately a 100 to 1 reduction. There is a positive and automatic knockout to the power feed. There is also an auxiliary worm which can be thrown in when it is desired to use the hand wheel feed for rapid movement of the carriage.

The carriage in the photograph is of special design to hold a Liberty motor cylinder. This is arranged with a quick acting clamp which centralizes the cylinder and holds it securely for the boring operation. When the proper depth has been reached the carriage feed is automatically tripped and the feed stopped. The carriage is supported on two extremely large heavy ground bars instead of on the bed as is the usual practice. This is to give direct support in line of pressure when the machine is in operation and prevent any distortion of the bed. The end pressure while boring is tremendous, and this is all taken up by tension in the bars with little or no strain on the bed. The bed has been made extra deep and wide, well braced with ties to give the machine a rigid foundation. An oil pan is provided for the cutting compound. This machine as can be understood from the above description, can, by slight changes in design of gearing, etc., be made to accommodate most boring operations.

CONVOY ORDERS

The convoy system is now an integral part of our naval policy, but it is only after much effort and considerable experience that it has been possible to bring it to its present efficient state. Credit is due not only to the Navy, which escorts our shipping, but also to the masters of the merchant ships which form the convoys, as without implicit obedience on their part and a thorough understanding of what is expected of them, the value of the escort's protection would be much reduced.

An important part of a convoy's organisation is the conference, which has been found invaluable and always necessary in the case of large ocean-going convoys. This conference is really a lecture which the master of each ship about to sail in the convoy has to attend in order to receive his instructions for outwitting "Fritz" during the forthcoming voyage.

Picture to yourself a smallish room with dirty whitewashed walls and a long deal table running down the centre. At one end is a raised platform facing a large blackboard covered with little discs; at the other is a small table littered with multifarious documents, guarded by a Naval Reserve officer.

Grouped round the table, some sitting, others standing, are about 40 masters of all ages; jovial-looking, fair-haired Swedes are mingled with tall and serious-looking Norwegians and Danes, while the remainder are obviously British. Some are attired in well-cut blue suits and "bowler" hats, others are content with a suit of "reach-me-downs" and a muffler, but the stamp of the sea is clearly marked on each face.

A corner of the room contains the commanding officers of the escort vessels, and in front of the platform stand the port convoy officer and the senior officer of the convoy itself.

The port convoy officer, who is a captain R.N., mounts the platform and gives his audience the general instructions for the voyage. Each ship is assigned her place in the convoy, which is shown in miniature on the blackboard. Emergency signals are explained and the importance of darkening lights at night and keeping a good look-out by day are particularly emphasised. Most of the masters are "old hands" used to convoys and the orders are not new to them, but nevertheless not a word or a shuffle interrupts the lecturer.

All the neutral masters speak and understand English perfectly and have unbounded confidence in the Navy, which enables them to follow their livelihood with a daily increasing degree of safety. For four years now these men have sailed in submarine and mine-infested waters with but little personal gain, knowing that their lives are in the balance on each voyage; but they never shrink from their work and carry on for the good of their own country and ours.

Notes are taken as the lecture proceeds, and finally the masters are asked if everything is quite clear and whether they have any questions to ask. One master is not quite certain of his procedure in the event of sighting a torpedo heading for his ship; this is at once explained to him. Another apologises for dropping astern during a previous voyage, explains how he was let down by inferior coal and hopes he will be able to maintain the convoy sped in future.

Get Ready For Peace Now

THERE may be quite a fight left in the Hun yet. It is well to reckon that the Hun war machine will reform this side of the Rhine and fight. With the whole caboose of them taking to their heels it's an easy matter to sprout a heap of cocksuredness that will do all sorts of damage.

That means that the war effort is to be sustained. At the same time there is no reason why manufacturers cannot plan ahead. One guess is as good as another regarding events that will take place after the war. But the one best guess is that business and trade will go to those who are in shape to go out and get it.

There are evidences already showing that plans are being made by some of the best executives on the continent to meet the period of uncertainty that will follow immediately the cessation of war. The head of one big concern announces to his selling force, which covers this continent, that his policy right now to protect his company is that no cancellations of contracts shall be allowed. It is not always possible to carry this out but there is good reason to urge it where at all possible. Cancellations, when they become chronic, kick the bottom out of business as fast as any other agency that is known. Manufacturers and dealers should protect themselves as far as possible in this way. Readjustments are hard to make in many cases, and in the majority of deals they are not satisfactory.

The selling forces in many cases have become "soft" since the autbreak of the war. Business has been pelted at them. They have not had to dig for their prospects. At best their work has been mainly seeing how close they could keep to delivery promises. It's good business right now to get the selling forces trimmed for the day they will have to get out and sell once more. It's good business to get the advertising campaigns in shape for the season of competitive business that is nearing.

None of these things mean that there should be any slackening on war efforts or production. They are all part and parcel of a sound and sane policy of good business.

Don't allow the cessation of war orders to find you at the stage where your only move is to fire the staff and spar for time.

Not Down to Brass Tacks Yet

THE people of this country may think that they know what it is to have the line drawn between essential and non-essential industries. As a matter of fact they know little or nothing about it.

There's a heap of wasted energy running wild in this country. If you take the trouble to do so, you can look around your own community and see it.

On a business street of Toronto there have been erected in the last few months four stores. It took labor and money and material to put them there.

One of the stores sells cigars, newspapers and magazines. Another deals in optical goods; the third is a music store and the four is a shoe shine stand.

The residents would have done very well, indeed, without any of these establishments coming into existence. The community was well served with cigar stores before. It was never known that a family had moved out because there was a lack of cigar stores. There are a number of optical parlors in the same district, and hundreds of places in the city where you could squint at the elusive letters and go out with a set of fixtures on the end of your nose. Of music stores and shoe shine parlors nothing need be said more than to add that to see a string of able-bodied men sitting on a bench while some other able-bodied foreigner dabs and whisks at their shoes is apt to give a sensible man a pain in the ribs. If the family altar needs to be revived, so does the family shoe shine box.

All that labor and all the labor needed for the upkeep of those places is, in the last analysis, non-essential. That case can be duplicated hundreds of times all over the country.

Canadians don't know yet what it means to get down to brass tacks.

We're Busy Dodgin' Germs

OH folks imagine nowadays that every place they turn, some person's waitin' for to hoist on them a Spanish germ. They see them settin' on the road, and campin' on the trees, and scatterin' forty different ways whene'er they hear a sneeze.

They're sprayin' dope on dollar bills that camp inside the bank, they're killin' germs that venture there, the fat ones and the lank.

You see a man come in the car, there's murder in his eye, to see if any germ-stuffed jay is comin' on too nigh—he sizes up the line what's there, and if he hears a sneeze, he trembles from his stomach up and wabbles at the knees.

And when he goes to get some grub he grabs the battin' card, and gazes at the things thereon and ponders long and hard.

He's sure the soup is full of germs, on fish they'll camp, 'tis true, and on the liver and the rice will dwell ten million Flu—the waiter, too, his eye looks bad, there's death upon his paw, there's torture written on his chest and sickness on his jaw.

That waiter should be run right in and planted in the coup, this thumb with sixteen kinds of germs has gamboled in the soup.

Oh, there ain't much fun in livin' now. I'd rather be a worm, what camps inside some lonely spot what's free from any germ, than hoofin' round the streets these days a-scared of folks like you, what's tryin' to fasten on to me big hunks of Spanish Flu.—ARK.

IF you are thinking of going out on strike, just remember that there are thousands of the best men this country has ever produced who have been taking their lives in hand for years now at $1.10 per day.

JUDGE A MAN BY STARTING POINT

Hugh Clark Worked and Asked Questions and Studied All At the Same Time.

EMPLOYEES of the Singer Sewing Machine Works at Clydebank, Scotland, at least those of the old guard whose memories go back 30 to 35 years, could tell you of a lad they all called Hughie. They could tell you how this little more than toddling lad worked in the packing rooms of that 30-acre plant. With reminiscent smiles they could tell you how, along in the year 1888, he soberly announced intention to go with his parents to Canada. And as he fitted the action to the word a few weeks later it is our privilege to report his measure of success in this land of recompense for intelligently directed effort.

HUGH CLARK

Hugh Clark, or "Hughie" still to his intimates, started work in Canada as a carder in the Standard Woollen Mills. With the lapse of 10 years in this Toronto plant he stood at the gateway to the age at which a young man either strikes out for the thing he wants to do most or passively accepts his lot and rears a grouch upon it. He could be a carder to the end of time or he could buckle down to grimy toil and lamentably neglected studies and so fit himself for the work he mightily wanted to do.

To his credit, young Clark arranged for a transfer to the fireroom in the Standard Mills. Here for four years he worked as a fireman in a double sense. That is to say, he stoked, and he fired questions at all and sundry who could let him into the mysteries of boilers, engines and anything and everything mechanical.

And at length, when he was ready, opportunity was ready too. The power plant of the W. A. Murray store, Toronto, needed an assistant engineer. Clark got the job.

Three years later this privately owned plant was closed. And where do you suppose was opportunity? Just a few blocks to the south-east or, to be precise, where Berkeley street is lost in a maze of railroad tracks, the Joseph Simpson Sons, Ltd., Knitting Mills had to have a night engineer. Clark proved that he was competent.

That is 13 years ago, and for these last 11 years he has been, and is to-day, mechanical superintendent of the Simpson Mills. So if you are ever tempted to doubt the value of a good correspondence course in steam and electrical engineering or to underrate the practical help a man can get from such a paper as CANADIAN MACHINERY, go and talk with Hughie Clark.

In the big game named "getting ahead in the world" he has made a creditable score. I say that well knowing it is never wise to measure a man by the position he holds to-day. Rather stand in his shoes, if you can, and drop your plumb line to the job at which he started.

THE Kaiser's big job now is not the winning of the war, but saving enough out of the scrap heap to provide underwear and fodder for himself and family.

* * *

THE Toronto "World" announced that the Page-Hersey Co., of Guelph, had secured a large order for 155 H.H. shells. These H.H. shells are something quite new to us. No doubt the H.H. stands for "Hun Hitting."

"You're fired!"
—Ireland, in Columbus Dispatch

CHEAP LABOR WAS NOT VERY CHEAP

(Continued from page 481)

civilized locality makes the general executive very chary of making a change. All these factors made life hard to bear in ordinary times, but with the advent of war, bringing with it the highly paid munitions work, the position of these factories went from bad to worse. Being within 30 miles of a large centre, with its enormous demand for labor and the high prices offering for the skilled and unskilled variety, practically all the help of any value decamped en bloc. Those that were left naturally demanded higher wages. These were granted but had no effect on production as the higher wages simply enabled these workers to earn the same or better money for less hours work, a situation they promptly availed themselves of. The position of the works manager who is expected to keep up production can readily be imagined. These cases are not exceptions but are quoted as concrete examples.

There is no question but that in both these cases money would have been saved if these factories had been located in a large centre without any initial saving due to cheap land and exemption from taxation and without the doubtful advantage of cheap (?) labor.

It would always be advisable when settling on the location of a factory to look into the general conditions, such as housing facilities, educational establishments, and general characteristics of the surrounding population. It would be a good rule for the party making the choice to consider if they themselves would like to be sentenced to live there and bring their families up. Man does not live by bread alone, and the neglect of considering this may often militate against the success of an industry where other things are most favorable.

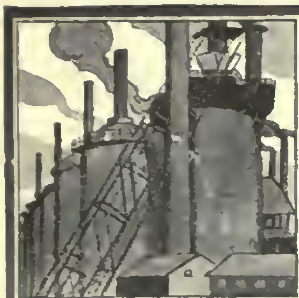
THE community is divided into two great classes now, viz., them what's had the Flu and them what ain't.

* * *

IT shouldn't be much of a job to grab the Turkish army if the soldiers wear the sort of trousers the Turks are generally pictured as wearing.

* * *

CIVIC officials used so many civic autos in Toronto going to the ceremony of opening a new road that private cars had to be secured to carry nurses to attend to influenza patients. All the ceremony needed to open the road was a couple of huskies to knock down the barricades.



MARKET DEVELOPMENTS

War Orders Growing Under German Peace Talk

The Only Uncertainty Now is in the Case of Machine Tool Dealers Where Deliveries Are Not Possible Until Well on in 1919—Some Firms Are Refusing Business That Carries a Cancellation Clause

THE war orders being placed by United States Government since the beginning of the German peace talk are greater in volume than they have been for some months past. That is the feeling in the steel industry and it is reflected in the trades most concerned in the production of munitions. As a matter of fact it will not be long before the production of shell steel is at the rate of 600,000 tons per month, a figure that has not been yet attained, but developments show that it is not impossible.

The only element of uncertainty entering into the situation now is for the machine tool trade. Their position is different from that of the contractor for munitions. Business placed now for war plants is placed on the known fact that delivery cannot be made for some months yet, and it will be still longer than that before the machines can come to the point where they will be taking their place in the production returns in the way of delivered shells. Figuring on business a month in advance is not the problem of the machine tool trade. Rather they are right now trying to figure out what conditions are apt to be toward the end of the first half of 1919. The rapidity with which events are developing on the Western front is not making their task any the less difficult. If the terms of the Allies are unconditional surrender it means that there will need to be a lot of metal shipped across the ocean before the last chapter is enacted.

The influenza epidemic is interfering to a rather serious extent with the production of munitions in some of the shops. For instance in one shop in Toronto where there are 2,800 hands on the payroll almost 600 are away now, and the disorganization is felt in the output figures.

Some of the large machine firms have sent out very explicit instructions to their selling agencies that they will not take on any business that has a cancellation clause attached to it. They are taking this step to protect themselves during the period of uncertainty that may follow the declaration of peace. Any business that they take on now must be on the distinct understanding that delivery will be made and the machine paid for regardless of the trend of the war. Of course there are other firms that have not made any such rules, and they are willing to consider cancellations, subject, of course, to satisfactory adjustments covering the labor costs already incurred.

SICKNESS CAUSES FALLING OFF OF PRODUCTION IN MONTREAL

Special to CANADIAN MACHINERY

MONTREAL, Oct. 24.—Industrial and commercial activities throughout this district have been seriously interfered with by the raging of the influenza epidemic that has been scouring the country. Many of the plants in Montreal are operating away below the maximum owing to the sickness of large numbers of their help. Production has been falling off for the past two weeks, and likewise deliveries, owing to the difficulties under which the railroads are operating. The demands for steel are as insistent as ever and the same regulations as those effective for the past month still apply. Essential requirements are still excessive with jobbers unable to obtain material for many of their customers. In general the situation has been little affected by current peace talk, but it can hardly eliminate the undertone of nervousness that appears to prevade the market. This has been reflected somewhat in the reduction of orders that are being placed for distant requirements. Plants working on American ammunition contracts are actively engaged in acquiring their full complement of machinery, and for this reason are unable to operate at the maximum. In this respect it has been intimated that little impression has been made by the possible approach of peace, as in all likelihood the contracts now under way will be completed.

Steel Production Affected

Efforts are being made to maintain operations in spite of the activity of the influenza that is biting into the numerous offices and factories throughout the district. The situation in regard to steel plates shows little relief and the difficulty in obtaining material except for the most necessary purposes is as acute as ever. Local mills are compelled to work under additional pressure owing to the number of men that are away, so that in consequence the general output is considerably below the average for the period. Dealers report that in some respects the delivery of material from the States has been delayed and the cause of this is generally conceded to be the prevailing shortage of help for the operation of the rolling stock. A factor that is beginning to influence the trend of activities is the possible effect that an early peace may have on the industrial situation. While to all appearances the business continues as brisk as ever there is some tendency to retrench, particularly in the direction of covering requirements for future operations. This has as yet not been felt regarding existing activities but the undertone is quite pronounced in many places. Operations on the American shell contracts are showing no reduction apart from the local influence of the raging disease, a feature that has depleted the local plants to no small degree. Asked as to what the effect of peace would be on those firms now working on these orders, CANADIAN MACHINERY was advised by a representative of Lyalls that it would make very little difference at least in the immediate future, as firms working on American orders would still continue to do so, as the initial contracts would be completed. However, in the event of peace he intimated that it was very unlikely that they could expect repeat orders, especially in connection with munition work, but this would not apply to many other accessories such as clothing and general equipment, as the men at the front would require replacements for such time as they were away from home or until they were discharged from the service. General conditions in all branches of activity show little change, and apart from the uncertainty that prevails, the situation is going on as usual, with prices holding firm.

NO CANCELLATION CLAUSES INSERTED

Machine Tool Dealers Are Playing Safe In Regard To The War Shops

TORONTO.—There is an element of uncertainty entering into some of the business transactions that are taking place or hanging fire just now. That is to be expected. It all comes back to the old question, "When will the war end." The man who can sit down and figure that out for you can do a great deal just now to tell the machine tool trade what the best move is.

The scrap metal situation is best described as being stagnant this week. Some of the large dealers state openly that they are not in the market for material at all.

Prices for the most part have remained at the levels of the last few weeks, although deliveries are reported more satisfactory.

Material Still Scarce

There have been some shipments of sheets reaching Toronto this week, but they are not in keeping with the business booked against them. Galvanized sheets that are being delivered now are selling for $11 up, mostly up. As a matter of fact, the $11 figure does not exist now as a selling mark, and prices are running at $12 and $12 50. Peace talk has had no effect on the calls that are made on the material. There is a fair amount of the lighter sizes in plate still on hand in Toronto, but for the heavier sorts the scarcity is felt. Ottawa does not sanction extension to plants, even for the production of munitions, but will grant permits for material that is required for the upkeep or repair of existing plants, with a view to keeping production up in size and quality.

Dealers are finding it hard also to keep up an assorted stock of tubes. Especially is this so in the smaller sizes. In pre-war days a dealer kept a standing order at the mills for perhaps 100 tons assorted per month. The mill knew just about how to mix them for lengths and sizes, and went pretty much on their own initiative in keeping the stock up. But since the war programme has such preference in almost everything now, all these arrangements have ceased to exist, and as a result it is not an uncommon thing for warehouses to find that they are out of certain lines almost continually.

The Scrap Situation

"We are practically out of the market at the present time," was the way in which one of the big yards in Toronto sized up the situation this morning. He was inclined to think that peace talk was to blame for his trouble, as there had been a very acute falling off in the week after the first real peace talk had come to the surface. As a matter of fact, there has not been the call for scrap for some time that has existed across the line. The prices that are quoted now are nominal in many cases, the dealers state. They are not keen to buy at the figures given because they have no place in sight now to dispose of the material, and they are not inclined to stock up their yards under these conditions.

The Machine Tool Trade

It would be useless to disguise the fact that there is an element of uncertainty entering into the machine tool business at the present moment. The trade knows quite well that the time must come when they shall get off war trade and make the necessary adjustments for a peace time footing. The approach of that season has not been lost sight of. One item that comes largely into the business is the indefinite air that is attached to deliveries. When orders are placed now it really amounts to contracting for business that will not take place until well into 1919, because machines ordered now could not be finished and delivered, and give production before well on in next year. If the thing were permissible, one might sum up the situation by saying that the machine tool trade want to play safe and yet handle all the business they can accomodate.

No Cancellations

Letters have been sent out by the heads of some of the largest machine tool firms on the continent giving absolute instructions to their selling forces that they will not accept any business now that has a cancellation clause attached. As a matter of fact there are cases where a substantial cash payment is asked for when the business is placed in order to protect the tool manufacturer against any eventuality that may turn up. Speaking of this matter the manager of one of the largest businesses in Toronto stated to-day, "We are going through our files now, and any business that has been there for three or four months is going to be well sorted. We want to know for a certainty if it is still good, and if not we want to get rid of it. It is not the time to be carrying any more unfilled orders than is necessary. Experience does not show that the making of adjustments has been satisfactory in the past. It is almost better to risk some future business and adhere to the non-cancellation idea. We have been trying to find out from Ottawa what is in the mind of the Munitions Board there, but so far this has brought us very little assistance.

Another manufacturer, who spent some time in Washington a week ago, stated that at that time there was no talk of any let-up in the manufacture of munitions, or in the matter of prosecuting the war. "These two things go together," he stated, "and the feeling in the American capital seemed to be that when you heard that peace had been signed you would hear that war

POINTS IN WEEK'S MARKETING NOTES

The production of steel has not been interfered with at all by reason of the peace talk.

—

U. S. Government orders for steel have been heavier since the German peace drive than they have been for some weeks past.

—

The output of shell steel in United States is now at the rate of about 600,000 tons per month.

—

Some of the users of scrap material claim that dealers have been getting high prices for material that does not come up in quality to heavy melting of good order, and that as soon as peace is declared there will be a tendency to "hit back" at these traders.

—

Some of the machine tool firms have sent instructions to their selling agents that there shall be no cancellation clauses attached to the business accepted by them from now on.

—

In one Toronto shell shop where 2,800 hands are employed, over 500 are off at present with the influenza, and production is being interfered with to some extent. One factory doctor states that he fears the spreading of the disease more by the men after they have returned to work.

—

One of the largest scrap metal dealers in Toronto stated that his firm was practically out of the market for the present. They are not buying except under very exceptional circumstances. They are well stocked and future sales are not much in evidence.

—

New York reports that the Teutonic peace talk has stimulated interest in the production of war material in that district.

—

Large orders are apparently to be placed for gas shells, to be made by the semi-steel process. Canadian foundries may take over some of this work.

contracts had been cancelled. Of course the feeling may have changed during the past week," he concluded, "but from what I could gather during my stay there it did not seem likely that the war work would stop for some time yet."

That feeling seems to be shared by a good many who are closely in touch with the situation. They do not believe that so great a thing as the German war machine is going to cave in all at once, and that peace will come in an instant. The feeling is that the German war machine has got to be smashed to a pulp, and that it is going to take a lot of material to do this

tile plant will be widely distributed; because of the urgent need of quick deliveries, practically all of the crane makers will share in the work. The Department has given a contract to the Barney Ahlers Construction Corporation of New York for the building of a gas defense plant on Governors' Island. The Durstan Gear Corporation, Syracuse, N.Y., is to manufacture transmissions for motor trucks to be used in France.

The Cast Shell Order

Two contracts for a total of 600,000 4.7-inch shells have been virtually closed with two manufacturing interests, but the confirmation of this order must wait the passing of the deficiency appropriation by Congress. It will be recalled that the Government is about to place contracts for 30,000,000 semi-steel gas and smoke shell, in this section, including 24,000,000 6-inch and 8-inch shells, all of which will be completely machined. The 6,000,000 4.7-inch shells will be only partially finished. It is estimated that to produce 250,000 six inch shells a day, 22 machining tools and ten tool room machines, including turret lathes and screw machines, will be required. Some of the plants that will help to provide these shells are already fully equipped and the Government will provide a machine plant for the foundries which have the necessary floor space to accept large casting contracts. If the machinery cannot be obtained from the regular machinery makers, arrangements will be made for manufacturers who have not previously made machine tools to enter the Government service. Foundry interests in the Birmingham, Ala., district, are being urged to accept contracts for 3-inch shells calling for an output of 80,000 per day.

Canadian Interests

Buying of machinery for the manufacture of pistols is still held in abeyance, but the Government is expected to act speedily to meet the needs of ten different concerns that have been given orders for Colt pistols and among these are: Carem Bros., Montreal, and the North American Arms Co. of Quebec. Orders in the United States have been placed with the Winchester Arms Repeating Co., New Haven, the Savage Arms Corp., which is operating a factory at San Diego, California, as well as one at Utica, N.Y.; the S.-S.-E. Co., and the Lanston Monotype Machine Co.. of Philadelphia; the National Cash Register Co., Dayton, Ohio, and the Burroughs Adding Machine Co., Detroit. Thos. A Edison, Inc., Orange, New Jersey, will manufacture adaptors for 75-mm shells and is about to come into the market for shop equipment.

It is an interesting fact that the Emergency Fleet Corp. will discontinue the building of ships which cannot be completed in 1919, and as a number of the yards are already behind in their contracts, the demand for marine plates and shapes will be less pressing than previously anticipated."

AMERICAN DEALERS HAVE TROUBLE GETTING SHIPMENTS TO CANADA

MANUFACTURERS have two kinds of problems in these days of stress. On one hand, there are those that stand out as unavoidable—such as scarcity of labor, difficulty in obtaining material, or in making deliveries—and finally, the "Flu" which seems to have mixed in and aggravated most of the other problems. On the other hand there are troubles that seem to be avoidable—which are all the more provoking because, very often, they seem to be beyond the capability of human explanation. Very often these problems are traceable to poor organization, or to a weak link in the chain of responsibility on which organization is developed. The crush of war work, for example, has brought to the surface the fact that in handling certain details official machinery is not beyond criticism—or to draw it more mildly, cannot always be understood.

Manufacturers who have been trying to maintain some kind of service on this export business are having their troubles—troubles that seem all the more troublesome because there seems to be no remedy—official or otherwise.

"Why, we have had goods made up for delivery for six weeks," said an American manufacturer, "and although they are wanted by a Canadian firm working on American war contracts we have the greatest difficulty in getting the necessary official permits. This should be a case in which the necessary machinery should work smoothly and with despatch. Speed is essential,and when there can be no doubt that the industry is working on munitions, there must be plain sailing."

"Should you desire the information," remarked another manufacturer, "I could probably tell you when there is a mighty fine ivory mine. We have had some steel on order here for weeks, but cannot get the necessary permit to shoot it across. Why? We have filled out all the information that seems necessary—except that there may be some doubt as to where my wife's great grandmother was born—but still the permit doesn't come. That steel is wanted in Canada by a firm working on an American contract. To my mind it makes no difference whether it is an American, British or Canadian war contract—we are all fighting the same thing—yet the permit machinery on essential material does not work smoothly. It's holding back important work."

As bearing out the statements by American manufacturers, a Canadian manufacturer engaged on an American contract, flourished a letter from U.S. headquarters, asking for some information that would help them form an opinion as to when they might expect their contract proceeded with.

"I am just writing them," said the manufacturer, "that just as soon as they release the necessary materials we shall proceed with the work. We have been held up for weeks. We have had the same trouble right here at home. There are officials who don't seem to realize that time is the essence of the whole matter."

The problem certainly seems to be a real one that there should be some remedy for—at least before the next war.

PEACE DRIVE CAUSES MORE WAR ORDERS

New York Says That Was the Effect Of Developments of the Past Week.

Special to CANADIAN MACHINERY

NEW YORK, Oct. 24—The Teutonic peace drive has stimulated rather than decreased war activities in this country. The Government is taking vigorous measures to push the output of both guns and projectiles. More contracts have been placed for war munitions in the last week and other important contracts are pending. As a result of these orders more machinery is needed for equipping new plants and in rounding out equipment of other works. It is notable, however, that October orders booked by New York machinery dealers have fallen below the average of September. The renewal of shell contracts increases the purchase of finishing tools.

The Ordance Department has given an order to the Marlin Rockwell Corporation for 75,000 light Browning rifles and for 15,000 aviation guns and an order has been given to the Pfau Manufacturing Co., Cincinnati, for over 100,000 water boxes. The Department has also placed further orders for machinery for equipping the Neville Island gun and projectile plant and the American Bridge Co., which is furnishing the structural steel for this plant, has now received definite orders for 57,000 tons, shapes which will be sufficient to meet matured plans well into 1919, but double this steel tonnage will be eventually needed. The two hundred or more small cranes for equipping this projectile plant will be widely distributed; because of the urgent need of quick deliveries, practically all of the crane makers will share in the work.

PEACE TALK HAS NOT INTERFERED WITH ORDERS OF U.S. GOVERNMENT

Special to CANADIAN MACHINERY

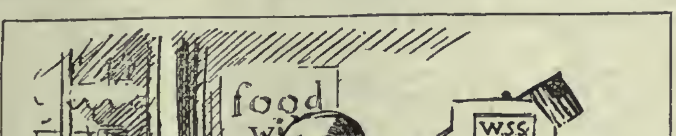
PITTSBURGH, Pa., Oct. 24.—Peace talk has attracted relatively little attention in the steel industry in the past fortnight. The steel producers are as anxious for peace as any, and face great complications and uncertainties in the markets and trade conditions generally in the period of re-adjustment, but they have no time to consider these matters being so busy endeavoring to swell production and distribute their output in strict accord with the regulations.

War Orders Heavy

In the matter of placing war orders for steel the Government has certainly shown no signs of relaxation for, if anything, orders have been heavier since the German peace drive started than the average of preceding months. Three large batches of orders for sheets have been distributed, making the buying the heaviest for months. Recent orders include 32,000 tons of 80-pound rails, for General Pershing, together with 150 locomotives. The 40,350 cars for General Pershing, on which bids were recently taken, are likely to be allotted shortly and the filling of the orders may further delay completion of the 100,000 freight cars which have been on order for domestic roads for several months.

Shell Steel

Fresh pressure is being exerted to secure still more shell steel. One important wire producer in the Pittsburgh district, which was kept off shell steel business for a long time on account of the need for its wire products, began making shell rounds a trifle over a month ago on one of its continuous billet mills formerly serving its rod mills, and this interest has now been asked to increase its shell steel production by 40 per cent. A little information has leaked out as to the actual tonnages of shell steel produced. It appears that in the early months of the year the total production was running at the rate of about 350,000 tons a month. The rate increased until recently it passed 500,000 tons a month, and a rate of 600,000 tons is expected to be attained this month or next. The indication is that the total shell steel output in the calendar year will be about midway between 5,000,000 and 6,000,000 tons. At 600,000 tons a month the output would represent approximately 18 per cent. of the total finished rolled steel output. The proportion of the ingot output involved in making shell steel is considerably larger than 18 per cent., by reason of the heavy discard required, but in practically every instance all the discard steel that can possibly be utilized is rolled into one finished form or another, chiefly for war purposes. The War Industries Board for several months past has been keen to find war uses for shell discard steel and has been quite successful. As a rule, when fresh orders are given a mill to roll shell steel, orders are given at the same time for the utilization of the discards, and only the material that cannot be rolled goes back to the open-hearth furnace as scrap.



The Kitchen Rangers cited for gallantry.
—Cesare, in New York Evening Post

Scrap Supplies Slightly Better

Reports from consumers in the past week are of slightly better supplies of scrap. The mills still claim they are very short of scrap, but on the whole the situation is a trifle easier. One theory to account for the improvement is that many railroads, finding labor so scarce, have adopted a practice of selling their scrap as gathered, without attempting to sort it, and this gets the material into the market sooner, though, of course, the supply in the long run would not be increased by the new practice. The Pennsylvania Railroad continues to sort and grade its scrap, and has been canvassing consumers with a view to their making contracts to take offerings in one grade or another, the contracts to run for three to six months. Hitherto the system has always offered its accumulation monthly, as a fresh offering. Another observation made as to increased supplies of scrap is that with the heavier deliveries of cars and locomotives to the railroads the roads are scrapping more old equipment. The scrap dealers have been thinking rather keenly on the subject of peace and recognize that when peace comes consumers of scrap will be prompt to "get back" at dealers for the trying experiences they have had, particularly in the matter of dealers holding extremely indifferent grades of scrap at the full heavy melting steel price of $29 delivered, material which mills say would frequently not bring $10 a ton in ordinary times Just now, with all mills striving for the last possible ton of output, they are forced to buy the scrap that is offered, but when opportunity comes to let down on the pressure their policy in the matter of buying scrap will be quite different.

Priorities for Controlled Consumers

For several weeks past the conservation division of the War Industries Board has been making agreements with various manufacturing consumers of iron and steel, whereby these consumers would limit their operations to certain rates, based on former practice. In many instances the arrangement has been for the consumer to operate during the last four months of this year on an average, at not to exceed one-half the average rate in a four-month period in 1917, i.e., production in the four months to be "50% of four-twelfths of the production in 1917." In the majority of cases these manufacturing consumers had no definite prospect of getting any steel, under the present regulations, to operate at all, and questions have been asked whether they were to be given any assistance.

The War Industries Board has now undertaken to grant certain priorities to manufacturing consumers who have entered into these arrangements. The degree of priority that will be given is not announced, but whatever it is it will be helpful to consumers who otherwise would have no claim for steel except through their being on the preference list. With nearly all the mills the priority orders are absorbing the output, leaving nothing for the preference list. The agricultural implement trade is an exception to this practice, as it already has B-2 priority, given as "automatic priority" in circular No 4 of July 1 last. This industry is limited to a 75 per cent. operation in the twelvemonth beginning October 1, 1918.

When Peace Comes

There are very few in the steel trade who think that the diplomatic interchanges of the past fortnight indicate a balance of probability that peace will come in the near future. The strongly preponderating feeling is that there is several months of hard fighting ahead, the actual time on the calendar depending largely upon weather conditions, which will determine how much of the fighting can be done this winter.

One thing, however, these diplomatic interchanges are regarded as suggesting rather clearly is that when peace does come, eventually, it will come suddenly. There will not be a long period of uncertainty. Acordingly, the change from war time to peace conditions in the market, and in the trade generally, will be a sudden change, not a gradual one. There have been strong intimations lately from Washington that the Government purposes to retain control of industry for a while after peace becomes assured, but the nature of the contemplated control is not known. While it has been pointed out that shell steel oreds would probably be cancelled instantly, while orders for shipbuilding and for the domestic roads would, of course, stand, there is thought in some quarters that the Government would early make a stand for lower prices, on the ground that with peace conditions and less pressure for tonnage output, steel could be made somewhat more economically.

CROWN PRINCE WILLIE HAS WRITTEN LETTER TO HIS "PAPA"

An American agent in Toronto for a big machinery corporation in the U. S. had the following sent from some of his American friends. It gives the U. S. view in an entertaining way:

On the Run, Somewhere in France.

Dear Papa,—I am writing on the run, as the brave and glorious soldiers under my command have not seen the Rhine for so long that they have started back that way, and, of course, I am going mid them. Oh, papa, dere has been some offel dings happened here in France. First, I started in my big offensive which was to crush de fool Americans, but dey know so little about military tactics dat dey will not be crushed be like I want dem. I sent my men in der fight in big waves and when dey got to the Americans dey all said "Boo" as loud as they could holler. Well, according to vat you haf always told me, de Americans should haf turned and run like blazes. But vat you tink? Dem fool Americans don't know anything about war, and instead of running de odder vay, dey came right toward us. Some of them was singing something about "Ve von't come back till it's over over there" or some other foolish song, and some of dem laffin like fools. Dey are so ignorant. But dey are offel reckless mit der guns and ven dey come toward us it was den dot my men took a notion dey vanted to go back to der dear old Rhine. Ve don't like de little old dirty Marne river anyhow. And, oh, papa, dem Americans use such offel language. Dey know nothing of kultur and say such offel dings right before us. And dey talk blasphemy, too. Vat you tink dey said right in front of my face? One big husky from a place dey call Kansas, he said—oh, papa, I hate to tell you vat an offel ding he said—but I can't help it. He said "To hell mit der Kaiser!" Did you ever hear anyding so offel? I didn't tink anybody would say such a offel ding. It made me so mad, I wouldn't stand and hear such offel ting so I turned and run mid der other boys. Vas I right? Vat? And, oh, papa, you know them breast plates vat you sent us—can you send some to put on our backs? You know we are going der odder way now and breast plates are no good, for der cowardly Americans are shooting us right in der back. Some of our boys took off der breast plates and put 'em behind, but der fool Americans are playing "Der Star Spangled Banner" mit machine guns on dem plates. Can't you help us? You remember in your speech you said nottings could stand before der brave German soldiers. Oh, papa, I don't believe dose ignorant Americans ever read your speech for dey run after us just like ve vas a lot of rabbits. Vot you tink of dot? Can't you send 'em some of your speeches right avay? Dey don't know how terrible we are. Can't you move my army back to Belgium vere ve von all our glory? My men can vip all de vimmin and children vot dem Belgiums can bring up. But dese Americans are so rough and ignorant. Ve can't make 'em unnerstand dot ve are der greatest soldiers on earth, and ven ve try to sing "Deutschland Uber Alles" dey laff like a lot of monkeys. But ve are getting the best of the Americans. Ve can outrun dem. Papa, if ve are not der best fighters on earth ve sure are de best runners. Nobody can't keep up mit us ven ve tink of der dear old Rhine and my army never did tink so much of dot dear old river. Let me know right avay vat to do by return post office.

Crown Prince Willie.

SYMPATHETIC STRIKE FROWNED ON BY LAW

Wider Application of the "No Strike" Order Is Now Under Consideration

Ottawa.—Wider application of the no-strike order-in-council is understood to be under consideration. Prosecutions so far in Calgary have been taken under the provisions of the Industrial Disputes Investigation Act, which provides penalties for men engaged in certain industries who strike without first applying for a board of conciliation. This course was taken because there was doubt whether the original strike was declared before the no-strike order was approved by the Governor-General.

But, it is pointed out here, sympathetic strikes are in a different category. Any declared since the approval of the order come under its provisions. Not only are the penalties heavier which may be imposed by the civil courts, but the order contains a work or fight provision which may be put into effect. In scope, it goes farther than present applications of the Military Service Act. No married men have been called to the colors under the Military Service Act. The work or fight provision includes all men of military age, whether married or single.

"Any male person, employer or employee of military age as defined by the Military Service Act," reads the provision, "who violates any of the hereinabove enacted regulations and any director of such military age of any company who acquiesces in the violation by the said company by any of said regulations, shall ipso facto be deemed to be a soldier enlisted in the military of Canada and subject to military law for the duration of the present war, and of demobilization thereafter and shall forfeit any exemption granted to him and any right to apply for or obtain any exemption from military service under the Military Service Act."

It is emphasized that there is no desire to cause undue hardship by rigid application of the order-in-council, and hope is expressed that satisfactory settlement will be reached before such a course is rendered necessary.

HALF BILLION IN NEW SHELL ORDERS

Which Means Busy Times Ahead For War Order Shops of the Dominion

Ottawa.—It is officially announced that up to September 30 manufacturers in Canada had produced 68,000,000 shells and 75,650,000 forgings.

The war authorities are making preparations as if there was no peace in sight and orders on a larger scale than ever are being let by the Imperial Munitions Board. The orders for the coming year will run nearly half a billion dollars.

Some Methods of Fighting the Influenza

It Has Always Traveled From East to West, and the Last Scourge Was in 1889-1900—Known as Far Back as 1510—Some of the Things to do if You Feel You Have It

By COMMISSION OF CONSERVATION.

INFLUENZA, which is now sweeping over Canada from one end to the other, is a very old disease. It was known in ancient times, and as early as 1510 it overran the whole civilized world. For centuries it has periodically swept over various parts of the world. The last great world epidemic was in 1889-1890 when it was generally known by the French name of la grippe. The disease has always travelled from east to west.

Symptoms

The symptoms are similar to those of a heavy cold; more or less severe headache, cold in the head and throat, fits of sneezing, flushed face, chills, aches and pains in the back and limbs, pains in the eye-balls and behind the eyes, general physical depression, and temperature rising to between 101 and 104 degrees.

How to Prevent It

As it is such an old disease, doctors have naturally learned a great deal about its prevention and treatment. The first principle of prevention is to keep away from those infected, and the second, to build up the germ-resisting parts of the body by eating nourishing foods, dressing comfortably, getting lots of sleep, and by living in the open air and in bright, well-ventilated rooms as much as possible. The mouth, throat and nose should be systematically and frequently disinfected by antiseptic inhalations, sprays and washes. Such preparations as chloretone and listerine are well adapted for this purpose.

In fighting previous epidemics, doctors found quinine a useful preventive. One grain of sulphate of quinine mixed with (but not dissolved in) a wineglassful of cold water makes an excellent antiseptic gargle. The anti-microbic properties of quinine are well known and its use as described above at once relieves the symptoms of sore throat, which result from the strain of the fight between the white blood corpuscles and the invading germs in the tonsils—the body's first line of defence. Quinine is also given internally with success as a preventive. In one of the more recent outbreaks in Europe, an experiment was tried in which the men of one squadron of a regiment of cavalry were each given 7½ grains of quinine in ½ ounce of whiskey daily for 22 days, whilst those of the other squadrons were given none. The latter squadrons had from 22 to 44 cases each of influenza whilst the squadron treated with quinine developed only 4 cases. Inhalations of oil of eucalyptus, thymol, oil of mountain pine and the like are also valuable as preventives.

How to Treat It

When a person is struck by influenza, only one course lies open. That is to take to bed with the least possible delay, and call a doctor. Rest, warmth and quiet are three sovereign remedies of the primary disease, and the best preventive of its more deadly complications, of which pneumonia is the most frequent. While there is no specific for influenza, yet there are many drugs which play a useful part in relieving it, such as quinine, aspirin and various tonics, anti-neuralgic,antiseptic, and heart medicines, to be prescribed by the physician in charge.

What to Eat

The dietetic rules which apply to any fever apply equally to influenza. Liquid foods at first, solids a little later on in a gradually ascending scale from lightly boiled fresh eggs to chicken, roast joints, etc. Water, cold or hot, may be sipped or "egg water" may be given. This excellent dish is prepared by blending with a pint of cold water the whipped whites of from 2 to 4 eggs, flavored with salt or cinnamon. Then the animal broths may be given. There are many cases in which even the lightest foods are spurned with loathing and common sense must be used in adapting diet to the particular case in hand.

Precautions Against Influenza

(1) The sick should be separated from the healthy. This is especially important in the case of first attacks in the household.

(2) Discharges from the nose and mouth should not be allowed to get dry on a pocket handkerchief or inside the house, office or factory. They should at once be collected in paper or clean rags and burned. If this cannot be done, they should be dropped into a vessel containing water.

(3) Infected articles and rooms should be cleansed and disinfected. Use disinfectants everywhere. Wash the hands frequently.

(4) Those attacked should not, on any account, mingle with other people for at least a period of ten days from the commencement of the attack. In severe cases, they should remain away from work for a longer period.

(5) Special attention should be given to cleanliness and ventilation. Warm clothing should be worn, the feet should be kept dry and all unnecessary exposure avoided.

HOW ONE OF THE LARGE U.S. FIRMS IS FIGHTING THE FLU

FOREMOST among the industries in guarding against the "flu" is the S. F. Bowser & Co., oil tank and pump works, of Fort Wayne, Ind. The officials have organized a health campaign for the benefit of all employes, as well as for the benefit of the city itself. Stations have been installed about the plant buildings which are easily accessible to all, and every employee of the big works is requested and expected to have his or her nose and throat sprayed at least twice daily.

Specially instructed attendants for the spraying are on hand at all times, the service is absolutely free, the company paying the entire expense. Special bulletins have also been posted instructing the men and women on the care of the nose and throat. The influenza germs are in the air in the form of dust and naturally attack through these organs, therefore, every precaution possible should be taken. Spraying of the nose and throat is one of the greatest preventives.

As a further precaution employees have been sworn in as deputy health commissioners with full power to enforce all rules and laws of the health department. It is their duty to take action (drastic, if necessary) to prevent the spread of the disease through spitting, coughing or sneezing, and to report all cases, however slight.

Employees of the factory and office have been instructed to report all cases to the deputies. Any employee showing the slightest symptoms will be sent home immediately. The employes are all responding with a will to the treatments, realizing that everything is being done to insure their health and keep them at their different tasks, which are so essential in the maintenance of the war.

All spittoons of any kind have been removed, as one of the common mediums of transmitting the germs of influenza is through spitting. All employees are also requested to refrain from spitting on the premises.

The Bowser scheme of precaution is a forerunner of similar campaigns which are being inaugurated among the larger plants. Officials of the General Electric Works are devising plans along similar lines.

The Poster Used

The following poster is placed in the Bowser works:

To the Heads of Factories, Managers of Department Stores, and all Institutions where numbers of men or women are employed:

Pursuant to a resolution of the board of health you are hereby ordered to exclude from your workshop, office, or store, everyone suffering from any of the symptoms of a cold. Coughing, sneezing, or a running nose are sufficient cause for sending an employee to his home, where he or she are to stay until these symptoms have disappeared. Refer immediately all violations of health laws to the health deputy in your institution or to the board of health, telephone 715. —E. A. CRULL, Health Commissioner.

Spittoons removed from factory. One of the common mediums of transmitting the germs of influenza in through spitting. It has therefore been ordered, effective Thursday, October 17, 1918, that all spittoons be removed from factory and factory offices. Deputies are charged with the enforcement of the rule that there shall be no spitting anywhere on the premises.

Care of Nose and Throat. The influenza germs are conveyed about in the air in the form of dust and naturally attack through the nose and throat, therefore, every precaution possible should be taken. Spraying of the nose and throat is one of the greatest preventatives. Spraying stations have been located both in the factory and office.

We expect every employee to have his or her nose and throat sprayed at least twice daily, for which no charge is made.

Deputies—Their responsibilities. As a further precaution deputy health officers have been sworn in with full power to enforce all rules and laws of the Health Department. It will be their duty to take any action (drastic if necessary) to prevent the spread of the disease through spitting, coughing or sneezing in public; and to report all cases however slight. The deputies for S. F. Bowser & Company are (a list of twenty names follows):

Employees are requested to report all cases to one of the above. Employees are to be sent home when symptoms appear.—S. F. Bowser & Co., by order Board of Health.

TRADE GOSSIP

Amalgamation in Steel Trade.—The W. J. Crouch Company, Incorporated, and Rownson, Drew & Clydesdale, Inc., announce the amalgamation of their respective organizations. All trading and manufacturing operations henceforth will be conducted under the name of Rownson, Drew & Clydesdale, Inc., with general offices at 68 William street, New York.

In future the name of "Crouch Steel" and all that it implies will be linked with the century old traditions of the house of Rownson, Drew & Clydesdale, which should be a guarantee to their customers all over the world of the highest in "service."

Mr. '. G. Donald, president of Rownson, Drew & Clydesdale, Inc., will continue in this office, while Mr. I. Smullyan, president of the W. J. Crouch company, Incorporated, will act as managing director of the new firm.

Messrs. Victor E. Karminski and A. E. Hearne, both treasurer and general manager of the W. J. Crouch Company, Incorporated, and Rownson, Drew & Clydesdale, Inc., respectively, will in future act as joint general managers of the new concern, Mr. Karminski conducting the Crouch Steel Division, and Mr. Hearne directing all other trading operations.

Mr. H. Lad Landau, assistant secretary and general manager of sales of the W. J. Crouch Company, will continue wit hthe new concern. So will other leading officers of the company, such as Mr. John H. Allen, purchasing agent, who will in the future be assisted by Mr. M. Greenberg of Rownson, Drew & Clydesdale, Inc.; Mr. Albert Smullyan, comptroller; Mr. O. W. Andrews, traffic manager, and head of the company's licensing bureau, and all others occupying positions of trust with the old companies.

CATALOGUES

The United States Silica Co. have recently issued a descriptive booklet of their various products enumerating the excellent qualties of flint shot and illustrated by a number of excellent drawings, which effectively drive home its advantages. Flint shot is extremely hard and effects a considerable saving in freight, air and labor, and may readily be used on castings of any material, forgings, stampings, hot rolled bars or sheets.

The Armstrong Cork and Insulation Co., Pittsburg, describe their nonpareil high pressure insulation in a booklet recently issued. The desirability of minimizing the loss of heat from steam drums, feed water heaters, internally fired and locomotive type boilers, enamel and japan baking ovens' tanks, breechings, etc., has long been recognized. The advantages of nonpareil insulation for these purposes is dealt with and the reason for its excellence as a heat insulation explained. Its applications to various industries is shown in the half tone illustrations of typical installations.

In Bulletin No. 104 the University of Illinois have published the results of an investigation undertaken to determine the rigidity of riveted joints in steel structures and valuable data have been secured. Tests were made on full-sized members with different connections. The distribution of the stresses in a rectangular frame depends upon the rigidity of the connections. In analyzing the stresses in such a frame it is customary to assume the connections are perfectly rigid. If they are not, it is apparent that the actual stress may not be equal to the computed stress. In addition to determining the rigidity of riveted connections, analyses have been made to determine the effect of lack of rigidity upon the distribution of stresses in a frame.

The Armstrong Cork and Insulation Co. have issued a descriptive booklet dealing with their lineotile floor covering. The floor problem is always a vexing one. Nowhere is it more troublesome than in offices, banks, stores, church lobbies and places of similar character. Similar problems present themselves in the floors of certain rooms in private residences such as billiard rooms and kitchens. To meet need of a floor which would be suitable for such requirements this company has brought out the Linotile floor, a covering which fulfils the requirements of resiliency, silence, warmth, sanitation, durability and cleanliness at a reasonable cost. The various uses of the flooring are described, its advantages explained and numerous illustrations in color give a good idea of its attractiveness and adaptability to varying architectural requirements.

The Defender Regulator Co., Saint Louis, describe their various instruments for use in the efficient operation of the boiler room. In view of the necessity for conserving fuel literature on apparatus of this type is of special interest at the present time. Complete control boards are illustrated and draft gauges, vertical pressure and vacuum gauges, pyrometers, thermometers and complete gas analysis apparatus are listed and described in detail. Information is given on the proper location and use of instruments of this type and a sample boiler room report sheet is illustrated, which the company supply. This latter is an excellent means of recording detail operations in the boiler room, gas analysis and draft pressures.

Raised Them Himself

Food Controller Hoover told at a meatless-wheatless banquet a story about a poultry profiteer.

"A lady entered his shop," said Mr. Hoover, "and asked the price of chicken."

"'Them birds in the winder,' said the profiteer. 'Waal, they're very fine quality stock. I can't let 'em go for less than 94 cents a pound.'

"'Indeed!' said the lady. 'Did you raise them yourself?'

"'Yep', said the profiteer, absently. 'They were 70 cents yesterday.'"

How She'd Changed

"It looks as if Jones is better satisfied with his wife."

"Yes, he is. You see, he went back home on a visit and saw the girl he had been dreaming of for the past twenty years."—Life.

Not Necessarily

"'One wife too many!'" exclaimed Mrs. Wederly, as she glanced at the headlines of her husband's paper. "I suppose that is an account of the doings of some bigamist?"

"Not necessarily, my dear," replied her husband, without daring to look up.

Great Importance Of Buying Good Pig Iron

If it is Too High in Sulphur or Too Low in Phosphorus Trouble Will Follow Its Use—Fine Grades For Strong Castings Require a Careful Analysis

By E. STANDIFORD

WHEN you require a good clear pig iron, free as possible from dross, kish, oxide, sand, etc., the following analysis will be found an excellent grade. The percentage of "sows" must never vary to any great extent from the usual amount found in a strictly graded iron, according to the old fracture method.

Analysis of Foundry Pig Iron, No. 1

	Per Cent.
Silicon must not be less than	2.50
Sulphur must not exceed	0.03
Phosphorus should not exceed	0.60
Manganese should not exceed	0.50
Total carbon not apecified.	

The carbons will usually be between 3 and 4.50 per cent. in this grade. Any No. 1 foundry pig which shows on analysis less than 2.40 per cent. of silicon or more than 0.035 per cent. of sulphur should be rejected.

Foundry No. 2

	Per Cent.
Silicon must not be less than	1.95
Sulphur must not exceed	0.04
Phosphorus should not exceed	0.70
Manganese should not exceed	0.70
Total carbon not specified.	

The carbons in No. 2 will generally range from 2.90 to 4.20 per cent. Any foundry pig No. 2 which shows on analysis less than 1.85 per cent. of silicon or more than 0.045 per cent. of sulphur should be rejected.

Foundry Pig No. 3

	Per Cent.
Silicon must not be less than	1.35
Sulphur must not exceed	0.05
Phosphorus should not exceed	0.80
Manganese should not exceed	0.90
Total carbon not apecified.	

The carbons of this grade will usually be between 2.50 and 4 per cent.; if No. 3 shows on analysis less than 1.25 per cent. of silicon or more than 0.055 per cent. of sulphur, it should be rejected. All grades of pig iron should be bought by analysis instead of by fracture; you should mix by analysis in the foundry, and the pig iron should necessarily follow the specifications; furthermore, if you accept as No. 2, which fails to fill the No. 1 conditions, you might eventually be overstocked with No. 2 and be unable to get the results aimed at in the cupola mixture; consequently an iron sold as No. 1 or any other grade should be rejected if not strictly within the specifications for said grade.

Test the Pig Iron

When a car of pig is received, it should be immediately sampled by an experienced man (professional sampler) who could select a certain number of pigs from different parts of the car which according to his judgment shall represent the average quality of the iron; these pigs should be broken and drillings from the face of the fracture should be sent to the laboratory for a chemical analysis; this analysis will decide the acceptance or rejection of the iron.

In case of dispute the furnace or the seller should have the right to re-sample the iron in conjunction with the buyer, each to select five pigs. Drillings from ten pigs, after being well mixed. could be divided into three different samples, one lot to be analyzed by the furnace, one by the laboratory and one by a disinterested chemist agreed upon by the parties in dispute. The two analyses nearest alike could then be accepted as the proper chemical composition of the iron.

Methods To Be Used

The following chemical methods could be used in the laboratory, viz.:

Silicon—Drown's method.

Sulphur—Evolution and titration with iodine (volumetric) as a rapid method, and the oxidation method (gravimetric) in all cases of dispute.

Phosphorus—Emmerton's method for rapid work and the molybdate magnesia method for very accurate determinations.

Manganese—Deshay's or the colorimetric method for rapid work and the acetate process for extremely accurate work.

Carbons—Carbons are worked generally by the colorimetric and combustion methods. In case of dispute analyses could be made by gravimetric methods.

Silver Gray (S. G.) or Silicon Pig

In the following analysis you can expect a pig iron medium high in silicon and not too low in graphitic carbon; this can be used as a softener.

	Per Cent.
Silicon must not be less than	3.00
And should not be more than	5.50
Sulphur must not exceed	0.04
Phosphorus should not exceed	0.90
Manganese should not he less than	0.30
Total carbon should not be less than	2.50

Any car of S. G. iron which shows on analysis less than 3 per cent. of silicon or more than 0.055 per cent. of sulphur should be rejected.

Ferro-Silicon Pig Iron

This is a specification of a pig iron with 8 per cent. silicon; the general range for silicon in this grade is from 6 to 12 per cent.

	Per cent.
Silicon must not be less than	7.00
Or not more than	12.50
Sulphur must not exceed	0.04
Manganese not specified.	
Carbon total not specified.	

As a rule the graphite carbon would be low, carrying from 3 to 0.50 per cent. Manganese may occasionally vary from 0.20 to 3 per cent. or more. Cars should be rejected which show less than 6 per cent. of silicon or more than 0.045 per cent. of sulphur.

Manganese Pig (Manganiferous Pig)

	Per cent.
Silicon should not be less than	2.50
Sulphur must not exceed	0.04
Phosphorus should not exceed	0.70
Manganese must not be less than	0.90
Carbon not specified.	

In this specification you get an iron from 1 to 2.50 per cent. manganese; the ordinary No. 1 pig iron running about 1.50 per cent. in manganese would fill all conditions required; as a rule higher the manganese the greater the proportion of combined carbon; combined carbon may range from 0.30 to 3 per cent. while the graphitic carbon may vary from 0.40 to 3.50 per cent.

I will now make a few remarks on manganiferous irons which may help to define the dividing line between the ordinary foundry pig and the regular manganese iron. Manganese pig is an ordinary iron made from ore containing somewhat more manganese than the regular foundry irons; it will run from 0.80 to 3.50 per cent. in manganese; it is added to foundry pig, in cupola practice, to raise the combined carbon, thereby increasing the strength. In a measure it neutralizes the effect of sulphur, removes excess of gas and prevents blow holes; it must be used with caution, as a low silicon and carbon, with high manganese, gives hard iron and alters the shrinkage; spiegel iron is used mostly in steel making, it is supposed to contain from 10 to 25 per cent. of manganese, but some authorities place the range from 3.50 to 20 per cent.

Ferromanganese contains from 25 to 90 per cent. of manganese; most of the ferromanganese on the market runs about 80 per cent. of manganese. With 80 per cent. of manganese present there is not much room for iron; the metal however, usually contains sulphur, phosphorus, carbon and silicon.

In cupola practice the amount of ferromanganese used is generally very small, consequently the effect of the other metalloids is not great. Manganese has a tendency to keep the carbon in the combined form; hence it lowers the graphitic carbon, thereby reducing the deflection; it neutralizes the effect of sulphur by reducing red shortness, and indirectly offsets the cold shortness or brittleness caused by high phosphorus.

In foundry practice the more manganese present in the pig the more silicon and graphitic carbon required to produce soft castings. For "chill mixtures" where great toughness is required, a pig with 2 per cent. manganese and less than 1 per cent. silicon is a desideratum.

Malleable Bessemer Pig

This specification will cover both the "common" and "straight" malleable Bessemer; when the straight Bessemer is specified it is understood that the phosphorus is not to exceed 0.10 per cent. straight Bessemer with 1 to 1.50 per cent. of silicon, about 0.60 per cent. manganese, under 0.11 per cent. phosphorus and below 0.04 per cent. sulphur would be satisfactory; in common Bessemer the following limit is specified:

	Per cent.
Silicon may range from	0.70 to 2.10
Sulphur must not exceed	0.045
Phosphorus must not exceed	0.15
Manganese may range from	0.30 to 1.20
Total carbon should not exceed	3.75

As a rule the combined carbon will vary from 0.30 to 1.30 per cent. and the graphitic carbon from 3.45 to 1.80 per cent. The iron should be rejected if the analysis shows more than 0.05 per cent. of sulphur or more than 0.18 per cent. of phosphorus.

Phosphoric Pig Iron

Phosphoric iron is used almost exclusively for small, thin castings, where great fluidity is desired; a very fluid iron is essential in thin work, as it fills every part of the mold and gives a clear, solid casting. Iron high in phosphorus is very weak and brittle under impact (shock) consequently it cannot be used where great strength is required; with high silicon and a high graphitic carbon the phosphorus may rise to 1 per cent. in the casting, but in chilled work, with low silicon and much combined carbon, the phosphorus must be kept below 0.30 per cent.

	Per cent.
Silicon must not be less than	1.50
Sulphur must not exceed	0.055
Phosphorus must not be below	1.00
Manganese may range from	0.30 to 0.90
Total carbon should not be below	3.00

Any car of iron which shows upon analysis more than 0.06 per cent. of sulphur or less than 0.90 per cent. of phosphorus should be rejected.

CONTROL OF COOLING IN CASTINGS

By D. STREET

For preventing the difficulties and defects that arise from the uneven contractions of irregular masses of metal for casting, Mr. Cecil Greenhill, Gloucester, has patented a method which depends on the application of electric heat to the thinner and less dense parts of the castings, with the object of keeping their falling temperature the same as those of the thicker and dense parts. As the method of application he suggests casting runners or ribs on the thinnest section and applying heat electrically by dropping electrodes in the molten metal and allowing the preliminary cooling to 1,300 degrees C. to make the joint. In cooling the thinner sections cool more rapidly than the thick ones, but if an electrical current is passed through more heat will be developed in the thinner ones because they have greater electrical resistance than the thicker ones. The amount of current required would not be as large as might appear at first sight, since only losses of heat have to be replaced. It would, therefore, not be anything so great as would be required to heat bodies of metal up to the temperatures at which they are treated, and it would be designed merely to keep the thinnest portions at the same falling temperature as the thickest ones. The method of procedure might be varied so that the current might be used either through the whole range of temperature in cooling or through portions only. In the case of steel it need perhaps be applied only at critical periods of steel formation, say, between 1,300 and 1,050 deg. C., after which the casting might be allowed to cool naturally without harm. Or the casting might be kept at 1,050 deg. and in shapes where the mould could be stripped the mould might be removed and the casting placed in the annealing furnace, thus saving reheating to this temperature for annealing.

His Excuse

It was the middle of the week when the young man appeared at the office to make his excuses and explanations.

"You should have returned from your vacation last Monday, sir," said his employer. "You were having a good time at that summer resort, I suppose, and thought you were entitled to three days of grace."

"N-not exactly," stammered the young man, with heightened color. "Laura, sir."

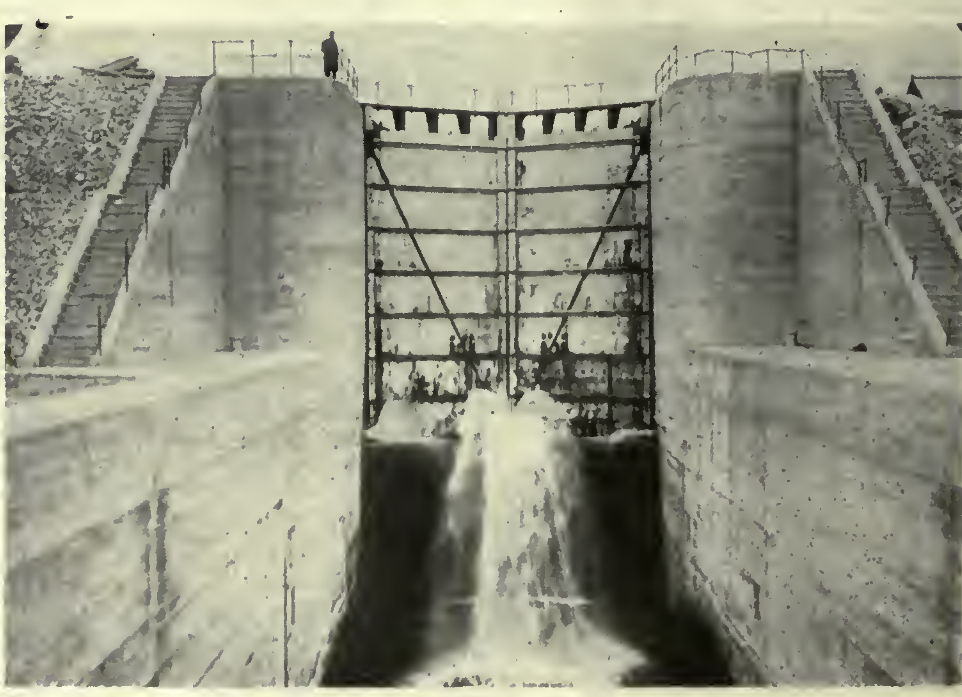
LOCKS ON THE TRENT CANAL

Picture shows the upper lock of the Trent Canal at Hailey's Falls, Ont. The lift here is 27 feet. The canal has only recently been placed in operation, and connects Peterboro and Trenton. Further work is in progress which will make it one of Canada's most important waterways.



THE STEERING OF SHIPS

By M. M.

All ships must possess the power to manœuvre, but exactly to what extent will depend on the type of the vessel and the use for which it is intended. Although all vessels possess the power to manœuvre it can hardly be said that the majority of ships are really easy to handle. It is true they are handled and handled effectively, but nevertheless captains often wish that they had more control over their vessels than is given them even by twin propellers and the ordinary rudder.

It will not be without interest to examine what takes place when helm is given to a ship. As the rudder at first goes over, the ship for the moment continues on her course and there is a sudden concentration of water between the rudder and the deadwood aft. This sets up an increase of pressure on both the rudder and the deadwood which pushes away the stern of the ship in the opposite direction to which the rudder is turning. The ship also moves bodily outwards. The instantaneous effect therefore is to move the ship along a course which is curved in the opposite way to that in which the ship is required to turn finally. In a short time the ship takes up a definite, but not really steady swing. This swing is helped by the pressure on the bow, the excess pressure on the deadwood aft being reduced. Shortly after this the vessel settles down to a steady swing, the pressures on bow and the rudder turning her, but the pressure on the deadwood aft is now on the opposite side to what it was originally, with the result that it retards the turning of the vessel. Equilibrium must eventually be established when the middle line of the ship takes up a definite angle to the direction in which the centre of gravity of the ship is travelling. This angle is called the drift angle. The distance between the original course of the vessel and the position of the ship when she is moving in exactly the opposite direction to her original one is called the tactical diameter of the vessel. If this is to be small the deadwood aft should be well cut away.

When the ship settles down on her turning circle, about the centre of which she rotates, there is some point—usually well forward of amidships—on the vessel which only has a motion along the middle line, every other point on the vessel really moving in some other direction. This point is called the pivoting point, and the resistance of the various parts under water to turning depend on their distance from this pivoting point. Since the pivoting point is forward of amidships, it follows that the aft deadwood is more effective in reducing turning than the forward deadwood.

When the rudder is first put over, the centre of pressure on it is below the centre of pressure of the force opposing the lateral motion of the ship, and in consequence the vessel at first heels towards the centre of the turning circle. When steady motion is established, centrifugal force acts on the vessel through a point generally above the water line and certainly above the centre of lateral resistance. This force is more powerful than the pressure on the rudder, with the result that the vessel heels outwards. Although this is very generally true, it would be possible to conceive of a case where the pressure on the rudder was so great and relatively high, and the centre of gravity of the ship, through which the centrifugal force acts, so low, that the ship might heel inwards on the turning circle instead of outwards.

It is, of course, well known that wind will affect the steering of a ship. If she is moving with the wind on the beam, the centre of pressure of the wind force on the above-water portion may be forward of abaft the centre of lateral resistance of the under-water portion. In any case, helm will have to be carried one way or another to correct the tendency of the wind to turn the ship. This will always decrease the speed of the vessel. In one particular case, it so happened that the centre of pressure of wind was abaft the centre of lateral resistance, the deadwood aft was cut away, bringing the latter point further forward, making matters worse, so that a good deal of helm had to be carried with a beam-wind.

It is generally understood that wind can affect the speed of a ship a good deal. If the wind is directly ahead, it will retard the motion of a ship considerably by direct pressure, although it will not affect the helm. If it is on either bow, it will not only retard the speed on account of its direct pressure, but also by the fact that helm will have to be carried to keep the vessel straight. With wind directly on the beam, helm will always practically be carried, and the speed of the ship will be retarded on this account, although the wind pressure has no direct effect.

Rudders are divided into several classes. The most common form is the ordinary merchantile rudder in which the whole area of the rudder is abaft the axis of rotation. For many years the most common type of rudder in war vessels has been the balanced rudder. This takes several different forms. It may be completely balanced and supported by the rudder head and a bottom pintle, or it may be completely balanced and also completely underhung and supported from two points on the rudder stock. There is another form of rudder described as semi-balanced, in which a small portion only of the rudder area is forward of the axis, the rudder being pivoted on the rudderhead and on one or more pintles, the portion of the rudder below the bottom pintle being completely underhung.

The ordinary mercantile form of rudder in general use because it is easily handled, although it is not so economical in form as some of the other types speeds of merchant vessels being generally small does not make the rudder unmanageable in size. The steering gear for it has to be larger and heavier than the more effective rudder of the balanced or semi-balanced type, all of its area being abaft the axis, the twisting forces acting on it are much greater than with the latter type. For vessels with cruiser sterns — which includes practically all war vessels—the balanced type of rudder becomes almost a necessity, although in the last few years certain merchant vessels fitted with cruiser sterns have still been given the ordinary merchant type of rudder, and it is doubtful if there is any reason to depart from this form in general practice. If particularly rapid manoeuvring is required there may be some reason for it.

There is not a very accurate way of working up the strength of rudders from first principles, as the forces acting on them have never been very accurately determined. Formulæ are used for this purpose in certain cases which are admittedly comparative. For the majority of merchant vessels the necessary rudder sizes are all given in the rules of the registration societies. It can hardly be said that a rudder is particularly effective in controlling a ship, in fact, if specially delicate manoeuvring is required in a vessel, twin screws must always be fitted to assist the rudder.

REPAIRING A LINE SHAFT

By A. L. Haas.

Although naturally unacquainted with the precise circumstances or nature of the fracture it looks as though the emergency repair described by J. H. Houldsworth on page 243, August issue was unduly complicated. Moreover, the repairs as described weakened the shaft and unless a very large factor of safety was present, it is probable that the repair would not have held.

In one classic instance of fracture to a steamer's propeller shafting, the ship was worked into port by coiling chain round the fracture, more to camoflage it than for any other reason, the break was very oblique and allowed ahead working at slow speed.

Faced with the conditions outlined in the sketch in the article in question, and presuming that the fracture was not a dead square parting of the shaft, a simpler artifice involving much less labor, is open as a temporary expedient.

A pair of shaft couplings can be mounted on the break if available, cutting the key ways is not a long job, a smith made clip of plate would probably serve to restore running conditions without keying at all, if made in any usual manner.

Solid drawn tubing, if available, and from saddle keys each end would, if the shaft were small, provide another alternative. A pulley boss or pulley complete would have served. A pair of shafting collars could also be impressed into service, the obliquity and inherent roughness of the break providing the drive.

In short it seems to the writer that the method chosen shews a want of resource which impaired the shaft strength by about 30 per cent and is by no means a commendable means of temporary fixing. It must have taken at least a day's work to effect.

BY buying Victory Bonds you are performing a greater service to yourself than to your country. As an investment it is the best thing the small investor has a chance to buy. It is safer than a bank, and more secure than a first mortgage. The revenue from these bonds is not taxed.

Shop Organization for Handling Victory Loan

How the Massey-Harris Co. of Toronto Have Handled the Advertising, Selling, Collection and Delivery of Bonds—What is Being Done in Other Industrial Centres of the Dominion

THE Massey-Harris Co. of Toronto, for the purpose of organizing for the Victory Loan campaign in their shops here, hark back to the days of the Old Testament, and estimate that one-tenth of his earnings is a fair amount for a man to put into Victory Bonds in the present great drive. At least that is the objective they set up. There is no compulsion about the matter. Mr. Leo S. B. Smyth, secretary of the Victory Loan organization in the Massey-Harris Co., discussing the matter with CANADIAN MACHINERY, stated: "We do not force men into the purchasing of bonds, and where a man has good reasons for not buying, we do not press the matter any further. But where we know that a man is in a position to buy, why our canvassers go straight for him and do their best to make a sale."

The Massey-Harris Co. have been through the Victory Loan business before, and know just about what is good and bad in the various systems of shop organization that have been tried out. They sold some $150,000 worth of the last loan in their Toronto shops. Including the works in Brantford and Woodstock, the total would run over $250,000. This does not include the subscriptions of any of the officials or directors of the company. The system they made use of is being used by several other manufacturers for the handling of this campaign, and officials of the company are quite willing that any part of their system, as outlined here, should be made use of by any company handling the sale of Victory Bonds to their employees, and undertaking to extend payments and make collections.

The Advertising Campaign

Some days ago the advertising campaign was started. All the posters that could be secured were hung up in the shops, and everything possible was done to bring the campaign to the attention of the employees as often and as forcibly as possible. Literature explaining the loan and the nature of the security provided was also given out. Along King street, where the works are located, bulletin boards were used freely with some of the campaign material prominently displayed. Everything possible was done to make it the topic of conversation and of chief interest all through the works.

When the employees were going out at noon and in the evening they were handed little cards bearing messages pertinent to the campaign. These were changed frequently, so that the men would not become accustomed to thinking that they had seen the thing before, and therefore pay no attention to it. Here are some of the messages on these cards. They were 2¼ inches by 4 inches, in two colors, red and blue:

WHAT IF PEACE SHOULD COME?

Whether we have an early peace or not will make no difference as to the need of the money to be raised by the Victory Loan, 1918.

Should peace come it will still be months before Canada's soldiers can be brought back and demobilized, during which time they will need food and clothing. Then there is the expense of transportation and demobilization—so let us still stick to the boys—buy Victory Bonds.

DUTY WITH AN OPPORTUNITY

It is our duty to back the boys at the front with our money. The Victory Loan gives us an opportunity to do so, and at the same time secure a safe investment at good interest—Make a loan or be alone.

Privileges in a free country always carry with them obligations. Buy Victory Bonds and secure freedom not only to the present generation but to posterity. Bondmen now—Freemen for ever.

Upon the success of the Victory Loan of 1918 depends not only the maintenance of Canada's military effort overseas, but also the continuance of national prosperity. On both patriotic and personal investment grounds, Victory Bonds should be purchased to the limit of ability.

The Shop Organization

"We have the organization all complete here," stated Mr. Smyth in discussing that part of the campaign. "The Toronto shop is divided into districts, according to the departments. We try as nearly as possible to have about two hundred men in each district. The plan used here is to divide on these lines, or as nearly so as possible:

Machine shop.
Steel department.
Woodworking shops.
Molding shops.
Packing and shipping.
Painting shop.
Printing department.
Knife and grinding.
Yard forces.
Office staff.

Each of these districts has a captain. This year the following are the leaders: J. G. Hossack, A. M. Rae, D. B. MacPherson, A. E. Shields, F. W. Hunt, J. N. Patterson, J. T. Orr, J. B. Warnock, George White, Leo. S. B. Smyth. Mr. Smyth, as well as being a district captain, has charge of the whole of the campaign in the Massey-Harris shops in Toronto.

How Campaigning Helps

On Monday, October 28, meetings were held in all the various departments. The factory whistle blew at nine o'clock, and meetings were held at ten different points. After that the campaign was considered as started. Here in brief is the attitude of the company in the matter as explained in some of the leaflets that were handed around the shop:

"In order that as many as possible of the Massey-Harris employees may take advantage of the opportunity to invest in Victory Bonds, the company has arranged to supply them to its employees and extend the payments over ten months.

"This makes it possible for almost everyone to buy a bond, as the payments are made so light they will never be missed.

"Should any employee adopting the above plan find it necessary to leave the employ of the company before the bond is fully paid up, he can either: Pay the balance and receive his fully paid up bond. Continue to make payments to the company as specified. If unable to continue the payments you can readily sell your bond.

Instructions to Canvassers

The following instructions have been prepared and are handed to the canvassers:

1. Work from this list and call on every man.
2. Supplementary list of new men added to payroll will be issued.
3. If purchaser is paid from the head office say monthly or weekly in place of check number.
4. Payments will be deducted from Mr. Powell's pay roll in first pay of each month. Those paid by Mr. Kelly will settle at Victory Loan desk in office.
5. Take all money offered and show amount under remarks. Have men bring cheques if convenient. If they draw on their bank account a cheque can be gotten.
6. Put daily totals of cash collected in space above and receive receipt.
7. If a man buys a bond for cash try and sell a second one on time.
8. Give every purchaser a button when application signed.
9. Try and sell bonds for cash to Chinese.
10. Endorse cash received in column number one on other side this sheet, also show amount of subscription in first column to right of name. Second and third sales (if any) go in second and third money columns to right of name. Add subscriptions and report to blackboard in cafeteria at noon each day.
11. Come to the lunch at cafeteria daily.
12. "Every man a bond."
13. "Every girl a bond."

The "list" referred to in the above list is a list of all the men employed in the works. It is prepared from the payroll and shows the check number, name, subscription, and the amount of cash paid to the canvasser. An estimate is made from the pay roll and it is figured on a ten per cent. basis how much each department should buy, and that amount is made the objective.

Means a Lot of Work

"We had 1,200 ledger accounts in the office here from the last campaign," stated Mr. Smyth, "and counting the other branches there must have been 2,500 accounts in all. The clerical work made it necessary for us to engage an accountant to look after this. We do not make any offers to the effect that the company will take the bonds over if the men do not want to finish the payments.

Information

These Papers are valuable and should be put in a place of safety.

Interest is Payable June 1, 1918, and each six months thereafter.

Interest Coupons are to be detached from BEARER BONDS and cashed at any Bank.

Owners of REGISTERED BONDS will receive their Interest by Cheque direct from Ottawa. They must remember, however, to send any change of address to, **Dept. of Finance, War Loans, Ottawa, Ont.** Better do so by Registered Letter. No Postage required.

If necessary to sell, it is best to deal with a responsible Broker.

MASSEY-HARRIS CO., Limited.
TORONTO.

1913 15c 5-18

THE ABOVE IS PRINTED ON A STIFF MANILA ENVELOPE—A GOOD PLACE TO KEEP THE BOND.

We do not encourage buying with a string attached to it. On the other hand we always try to deal as fairly as possible in the matter. If we find that a man has had considerable time off in any one pay, it is easy to see that he cannot stand to have his allowance taken off of that again, and an extension is given to him. The company will do all in its power within reason to help an employee hold on to his bond, but we will not go in on the understanding that we will take it off his hands any time he feels like dropping it. Much of this is explained in the material given out to the employees. In case of sickness or hardship the same rule applies, and an extension is granted to meet the case."

The payments are deducted from the pay envelope, and in place of the amount deducted a receipt for it is placed in the envelope; this has been found to be the most satisfactory method of handling this work. In some cases the card punching system was used, but this was not nearly as satisfactory, as it was necessary for the men to stand in line and generally wait quite a while for their turn to come.

The Massey-Harris organization has been complete and ready for some days, and nothing remained in the way of detail—except going ahead and selling the bonds. Although the officials are not mentioning any figures in advance, they are confident of an excellent showing for this great industrial plant in Toronto.

The Russell Motor Car Aiming at $250,000

Shop Has Been Divided Into Districts and the Canvassers Have the Situation Well Cleaned up Now—Little Booster Paper Makes Its Appearance in the Works Every Day

ORGANIZATION has been completed at the plant of the Russell Motor Car Co., for the selling of Victory Bonds to the employees there. The firm is setting up a quarter of a million as the objective, and they are putting on a campaign that has enough pep in it to clear up on the situation in a day or so. Three shifts are working there all the time, and on that account it is necessary to have more workers than in many other places.

The firm is issuing a diminutive paper every day, called the "Russell Victory Loan Booster." From the "Booster" we take the following concerning the shop organization:

We Go At It

"We," not the ordinary "we," but really "we"—us, the people—had a rousing good time in the Shell Shipping Room on Friday afternoon, when the Victory Loan campaign received its kick-off.

The general manager, Mr. Russell, rushed from the annual meeting of the shareholders and was right at himself in a ripping ten minute talk on the need for a Victory Loan, the meaning of a Victory bond and the duty of the Russell employees in buying Victory bonds. There was really nothing left to be said when he got through that hot talk.

Nevertheless, our old friend Boss Burt from Buffalo managed to throw in some hot bricks as to the pace set by the Russell employees over the line.

Chairman MacKay at once suggested that if the Russell people in Buffalo took a week to raise an average of $100.00 per head, the Russell employees in Canada, having been in the war four years longer than the Yanks, could obtain the same objective in two days.

The suggestion that the "Honor Flag" will fly from the Russell masthead, King and Dufferin streets, Toronto, Tuesday night met with a hearty response. After giving cheers for the boys and the Loan, and the singing of the National Anthem, the crowd went back to work with a resolve that the $100.00 per woman and man average was a sure thing.

Our Organization

General Committee.—Fred Adams; T. Yellowley; G. Ellis; F. Bavington; A. Bowman; N. Graham; J. W. Widdup; J. F. MacKay, chairman; G. W. Suggitt, secretary.

Tool: Messrs. Bowman and Dawson.

Millwright, Stores and Carpenter Departments—Mr. Graham, Mr. Stewart, Mr. Sorensen and Mr. Brown.

Engineering Department—Mr. Thompson.

Government Inspection—Fuse: Mr. Freedman. Shells: Mr. Dolson.

Office—General: Mr. Widdup. Time: Mr. Gartshore.

Machine and Stamping — Mr. Whyte, Mr. Smith and Mr. Kay.

General Manager's Appeal

The following is the appeal made to the employees by T. A. Russell, vice-president and general manager of the company:

Since the first year of the war the wheels of our factories have been kept turning almost continuously, producing munitions of war on a scale never dreamed possible in Canada prior to the outbreak of hostilities. When the last Victory Loan was offered for subscription in this country the employees of the Russell Motor Car Company took a place among the first half-dozen industries of the country in the percentage of employees subscribing for the bonds.

In view of all that has happened during the past year—the indescribable sacrifices made by our men at the front, the glorious victories they have achieved, coupled with the continuous employment and comfortable conditions under which we have lived—is it too much to expect that every employee of our company will subscribe for one or more Victory bonds? Would it not be a record in which each one of us would feel a measure of satisfaction in the years to come to know that at least to this extent we lent our aid in the defeat of the Huns?

The money already loaned by the Canadian people to the Canadian Government in the form of Victory bonds has made possible the carrying on of the ordinary affairs of the Government as well as the financing of the huge munition orders throughout this country. For the twelve months ending March 31, 1918, Canadian manufacturers exported over $636,000,000 worth of merchandise, an increase in three years of $551,000,000, or 648%. $20,000,000 per month has been advanced to the Imperial Munitions Board at Ottawa for the purchases of Great Britain in this country, and there has also been expended approximately $20,000,000 a month for other war purposes in Canada.

In one sense it does not seem proper to call a subscription to a Canadian Victory Loan a work of patriotism, for it is in reality a sound business transaction. The bonds are offered at par and interest at 5½%. The amount of the loan the Government is asking for is $300,000,000, but it is hoped that, as has been the case with former Canadian loans, the amount will be very largely over-subscribed. The bonds mature in 5 or 15 years, as desired by the subscriber, and may be converted into any future domestic issues of like maturity or longer made during the remaining period of the war. The bonds will be issued in denominations of $50, $100, $500 and $1,000. The bonds are exempt from taxes, including any income taxes imposed in pursuance of legislation enacted by the Parliament of Canada. The terms of payment are: 10% on application; 20% on December 6th; 20% on January 6th; 20% on February 6th, and 31.1/6% on March 6th; or 100% flat, on application. The selling campaign will open on October 28th and close on November 16th.

The world is watching Canada. Our money is required for the proper prosecution of the war, but, beyond this, there is great moral need of it. Is the spirit waning that has made possible the incomparable deeds of heroism on the part of Canada's men in France and Flanders? We believe not, but each one must answer for himself and herself.

An "Honor Flag" will be presented to every firm, the employees of which to the number of 75% subscribed to the loan an amount equal to 10% of the annual pay-roll. As in the past, we will be pleased to deduct the proper proportion from the pay envelope of each employee subscribing to loan. The schedule showing the amount of each payment will be handed to each subscriber at the time subscription is made.

It is our hope that the employees of the Russell Motor Car Co. will be first among the industrial establishments of Canada to fly an "Honor flag" from the flag pole of our building.

With this in view a central executive, representative of the company's various departments, has been formed, teams will be organized to canvass every employee, and it is hoped no bonds will be subscribed for outside of this organization.

Faithfully yours,
RUSELL MOTOR CAR CO.. LIMITED,
T. A. RUSSELL,
Vice-President and General Manager

KITCHENER FACTORIES ARE ALL READY TO MAKE THE LOAN GROW

KITCHENER, October 28.—This hive of industries is all alive on the eve of the Fourth Victory Loan campaign. The objective for Kitchener has been fixed at $1,700,000 but a determined effort will be made to reach the $2,000,000 mark before the campaign concludes. The objective for North Waterloo has been set at $6,000,000, which is considered to be a fair average for this community.

In a city with over a hundred industries, and the great majority of its inhabitants wage-earners an unusual opportunity presents itself to show their determination to help the cause of the Allies by buying Victory bonds, and thus placing at the disposal of the government their savings. In some of the factories of this city from 80 to 90 per cent. of the employees purchased bonds in the third Victory Loan campaign, and many of them are anxiously awaiting the opportunity to add to the number of bonds they are holding at the present time.

The Dominion Rubber System, the largest employers of labor in this city, will inaugurate a thorough canvas of all the employees immediately after the bells and whistles announce the opening of the campaign. There are four factories here and a friendly rivalry is already created between the different branches in order to become the possessors of honor banners for exceeding the objectives set for their respective industries. Superintendents Charles, Smiley and Kabel will supervise the campaign for the System, under the direction of the Central Industrial Committee.

The Williams, Greene & Rome Co., shirt manufacturers, will make a strong bid for an honor banner. The firm is making special arrangements to accomodate the employees in the financing of the purchase bonds, with the object of encouraging practically a 100 per cent. subscription.

The Kaufman Rubber Co., is another industry that promises to make a good showing. The organization of the staff is under the direction of Mr. Frank Dunham, and nothing will be left undone to secure subscriptions from every employee in this growing industry.

The furniture industries are being organized in groups and will be canvassed by specially selected enthusiasts. Similar arrangements are being completed by the Industrial Committee to canvas every factory, which will be done during the second week of the campaign, to be known as "Industrial Week." Previous to that time the workers will be circularized, and addresses will be delivered by prominent citizens, urging the importance of this hitherto German-speaking centre to show itself to be 100 per cent. British by buying Victory bonds until they feel it.

HOW CANADIAN VICKERS HELP THEIR MEN TO PURCHASE BONDS

MONTREAL, Oct. 28.—To obtain the enrollment of their employees on the list of subscribers to last year's Victory Loan the Canadian Vickers, Ltd., adopted a scheme to obtain the co-operation of their men that met with good response, by a very large number. Two plans were in operation and known as the Victory Loan Plan and the Canadian Vickers Plan. With the first we are all more or less familiar, but the operation of the latter method had features that generally appealed to the workers. The bonds were offered to the men on the payment of $1 per week for each $50 bond taken; that is, if the value of the bonds was $100, the purchaser was expected to pay $2 per week, a $200 bond would mean a payment of $4 per week. These payments were deducted from the weekly amount due to each workman—or member of the staff—for a period of 49 weeks, and the final or fiftieth week a further sum of 22 cents was collected for every $50 bond. This meant a relative saving to the bond holder of 78 cents, as he obtained possession of his bond after payment of $49.22. For a $100 bond the amount collected would be $98.44. This saving to the men was affected by the accumulation of the payments from the inauguration of the loan up to the first of May, when the permanent bonds were available; the Company, however, collecting the first six month's interest. The total number of men participating in the buying of bonds was upwards of 1,870, which was over 60 per cent. of the total number employed at the plant. The value of the bonds taken was invariably of $50 denomination, but in many cases $100 worth were taken by the men and $500 worth by the leading officials under the Canadian Vickers plan. The total amount realized under the company's plan was over $172,000, this amount being exclusive of any bonds purchased by the men from outside sources. This account is kept separate from the general funds of the company and is known as the Canadian Vickers Employees' Account. It has not been definitely decided what will be the policy this year, but Mr. H. Williams, the comptroller of the company, who is supervising the operation of the loan among the employees, anticipates that the same scheme will be operative this year with slight modifications to meet the conditions of the new bond issue.

STEEL WORKERS' PAY INCREASED

SYDNEY, N. S.—Official announcement was made at the steel works that all rates for employees whose earnings on 31st August last were less than forty-five cents per hour, would be advanced two and one-half cents per hour, that all other rates would be advanced two cents per hour, and that these changes were retroactive to last September. This means that all employees will receive with their pay for the last half of October a bonus equivalent to the amount of the extra pay for two months.

This is the third general revision of rates made during the current year in addition to many special or partial revisions, the combined effect of which is to raise the average daily wage of all employees over one dollar above the corresponding average for the year 1917—equal to about 33 1-3 per cent. between the years 1916 and 1917, and 5 per cent. between the years 1915 and 1916, and makes the average daily wage of all employees nearly double what it was in pre-war days. The minimum rate for unskilled labor has increased 114 per cent. since January, 1916.

LONDON MANUFACTURERS HAVE THEIR JOB WELL IN HAND NOW

LONDON. Oct. 28.—London manufacturers are bound to see that they are well represented among the purchasers of Victory bonds during the present campaign. With this end in view an industrial committee has been established with Arthur W. White, vice-president and manager of the George White & Sons, Company, Limited, as chairman. Associated with him are the following manufacturers: Charles H. White, manager of the London Rolling Mills Company; Frank. E. Leonard, of E. Leonard & Sons, Limited; Chester F. Stevens, assistant general manager of the Empire Manufacturing Company; Lieut. Col. W. M. Gartshore, vice-president of McClary Manufacturing Company, Limited; J. Fred Grant, president of the National Brass Company; W. H. Heard, manager of Spramotor Company; F. McCormick, of McCormick Manufacturings are chosen from among the men president of McClary Manufacturing Company, Limited, and T. W. McFarland, vice-president of D. S. Perrin & Company, Limited.

Mr. White as chairman has been working hard to get the various industries in line for the big drive. Small cards setting forth the need of the hour were enclosed in all the pay envelopes of London last week. Each employee in the several factories will be personally canvassed. This work has been undertaken in the above firms by the respective representatives on the industrial committee.

Meetings are being held in the workshops to arouse the interest of the employees. The speakers for these meetings are chosen from among the men who are best acquainted with the lines manufactured by the men whom they address.

A friendly spirit of rivalry has been developed between the various departments of each factory and also between the several factories. In this way the men are stimulated to their best work.

One million dollars has been set as the objective by the industrial committee. This is $400,000 more than the amount subscribed by industrial London to the Victory Loan of last year. With the efficient organization this year it is confidently expected that industrial London will go over the top.

GRAND TRUNK IN TORONTO ORGANIZE TO SELL WAR BONDS

The Grand Trunk men in Ontario are going "over the top" in valiant fashion in the big Victory Loan drive. The final details of the G. T. R. officers and employees' organization to support the loan of 1918 were decided upon during the past week-end, when superintendents of motive power, master car builders and other heads of departments were called together in Toronto from various centres in the province to discuss with General Superintendent Bowker and other officials the plans for ensuring a maximum subscription to the loan from the railway's men. C. R. Moore, assistant to operating vice-president; C. Manning, assistant to vice-president in charge of motive power and car departments, were present from Montreal to outline the general plan that has been adopted over the whole system.

They stated that from one end of the line to the other assurances were forthcoming of increased support for the loan. The Ontario lines of the Grand Trunk had always done splendidly in the patriotic campaigns, and the management of the road and all interested in the success of the effort to maintain the Dominion's war activities at their maximum were looking forward to the establishment this fall of a new Victory Loan record by the G. T. R. men in Ontario. Every man in the service is to be canvassed, and the company has made arrangements whereby the Victory Loan payments may be spread over a period of ten months.

BRANTFORD SETS TEN PER CENT. AS MARK IN THE VICTORY LOAN

BRANTFORD. Oct. 28.—Industrial Brantford is lined up solidly against the Hun. The organization for the Victory Loan, achieved almost at the last minute owing to the disruption which the influenza epidemic had brought about, is such that the manufacturers are confident that this city will go away over its objective, and that the factories' organization will have the largest share in bringing this to pass.

A rousing meeting of representatives of manufacturing plants and wholesalers was held in the local Victory Loan headquarters on Friday afternoon, with every class of industry represented. At this meeting steps were immediately taken for the formation of a thorough organization, to be based on specific conditions agreed to by the gathering. These were generally to have the example in subscribing set by the factories to the employees, and to leave no stone unturned to bring the latter to a realization of the great need for funds.

With the factory managements pledged to devote all of their funds that they possibly could to the loan, it was decided to appeal to the employees to put all the cash their pockets could spare into the loan, with a special effort being made to secure every factory an "honor flag." The factory managements will undertake to receive the men's subscriptions, and to turn the complete quota into the local headquarters as one big subscription. The firms will also undertake to carry the men's bonds, allowing small payments to be made as convenient to the men. Where, through sickness or other causes, bonds have to be forfeited by the employee purchasers, the firms will make every effort to dispose of the bonds without any loss to the employee. In every factory, shop committees will be formed by and from the men themselves, and to these committees every assistance will be given by the firm.

The appeal to be made will be an open one, but the objective of every shop has been decided on the basis of ten per cent. of the yearly pay roll for that shop. Thus, a firm with 250 men, with a pay roll of $300,000 would be expected to have its men in line for $30,000 in bonds, while one with 40 men and a pay roll of $40,000 would be expected to have its list up to $4,000. This is exclusive of the executive staff of the factory, or heads of departments referring only to the normal pay roll.

The committee chosen by the manufacturers to act for Brantford's industrial life as a whole, is composed of J. B. Detwiler, Steel Company of Canada; S. B. Chadsey, Massey-Harris; C. G. Ellis, Barber-Ellis, and W. J Verity, Verity Plow Company.

FEEDING A SOLDIER

It costs from 45 to 50 cents a day to feed a United States soldier. It takes about 478,515,000 pounds of beef a year for an army of 3,000,000 men.

The Morse Chain Company, Ithaca, N. Y., have recently sent us a copy of a booklet of data sheets containing useful information regarding silent chain drives. The booklet is illustrated with cuts of engines and drives and covers the subject of the number of teeth and links, lubricating and venting, sprocket materials, chain widths, chain contacts, chain adjustments, etc. It will be sent free.

Manufacturing Steel Bars for Rifle Barrels

Quality Required—Size of Billets—Furnaces—Care in Rolling and Heating Needed—Composition of Metal Most Desirable in Rolls

By W. S. STANDIFORD

THE great world conflict which is raging has resulted in a heavy demand upon our manufacturers for munitions and various implements of destruction; among the most important being rifles, of which large quantities are manufactured. As they are used extensively, the designs of the rolls, their proper adjustment and handling will be found interesting to the readers of this magazine. The steel is manufactured by the open-hearth process. It contains 0.40 per cent. of carbon and also 3.00 per cent. of nickel. This makes a very strong metal, capable of withstanding the high pressures exerted by smokeless powder which is used in modern rifles.

Billets

The steel for making the rounds is in the shape of 4 3-8 inch square billets, having rounded corners and cut to lengths to suit the engine power and furnace requirements of the mill using them; the average mill using a billet about two feet long. Where mills do not have a steel making plant the billets are usually purchased. As the heating furnace plays a most important part in the manufacture of steel bars, it will be considered first. There are various designs of furnaces used by manufacturers for heating steel, each one being built with a capacity suited to the roll equipment of the mill; the idea being in all cases to so proportion the work that the workmen on the day turn will have their steel rolled on schedule time and be out of the way when the night men report for duty.

As the output of finished material falls off in the summer time, which is due to the intense heat radiated from the furnace added to that of the weather, efforts have been made to devise means to keep the front of the furnace cooler, so that the heater will be able to keep the output up to the maximum tonnage. This is achieved by the use of a "water-curtain" shown in Fig. 1. It consists of a rectangular shaped sheet metal screen suspended by three door hangers placed on an iron track.

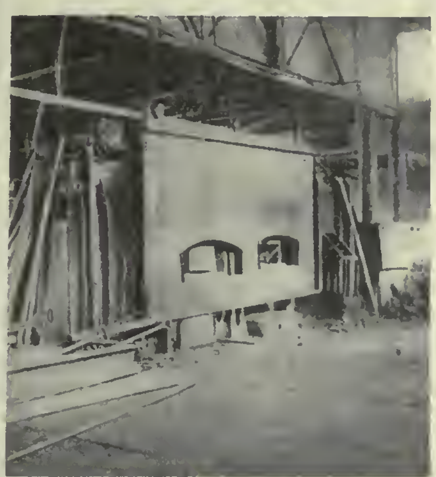

Fig. 1—Illustrates a good working heating furnace having the water-curtain in place. This is a very effective device and gives the workmen more comfort from the intense heat radiated from the furnace.

Water Curtain

The two charging doors seen in the illustration have angle iron around their edges so as to keep the water from flowing into the furnace. Riveted to bottom is a trough having a pipe on left side, which receives the water and conveys it to the bosh. At the top and extending lengthwise is the spray pipe; this has a row of small holes in the bottom which allows the water to flow against the side of the curtain. The spray-pipe is capped at one end and connected to the water supply at the other.

This curtain is not used in the winter time, it being easily removed by disconnecting the supply pipe and lifting the apparatus off the trolley track. In use, the water curtain proves very effective. Heating iron or steel calls for the utmost skill and care upon the heater's part, as the latter by his handling of the furnace can spoil the best metal ever made—too quick heating burns the outside, while the interior of the billet is not hot enough. If they are sent to the rolls in this condition the finished bars will be very brittle, splitting lengthwise in the middle when bent. If they are unevenly heated there being cold spots on the billet, the finished product will be wavy in appearance and varying in size due to the rolls springing more on the cold than on the hot parts. If the steel is left too long in the furnace it loses its quality by absorbing the gases given out by the coal —the result being that the metal is brittle and has little tensile strength compared with a billet that has been properly heated.

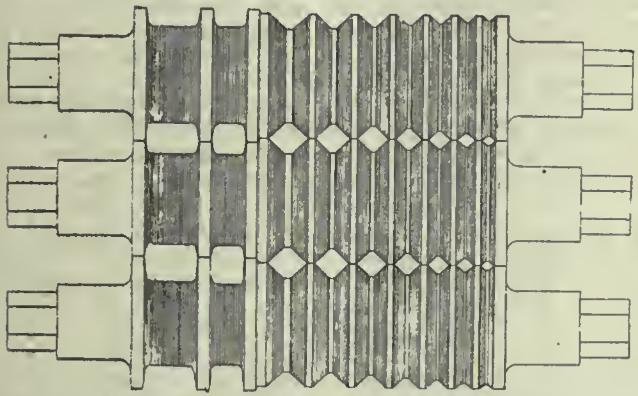

Fig. 2—Roughing rolls showing box and edging passes. Steel is entered into the deepest pass in bottom roll, goes from that into the top groove, it being then turned over on edge and inserted into the deepest edging pass, bar then is inserted into the top edging pass, which squares it up ready for the angle pass. These type of rolls are very efficient and give good service.

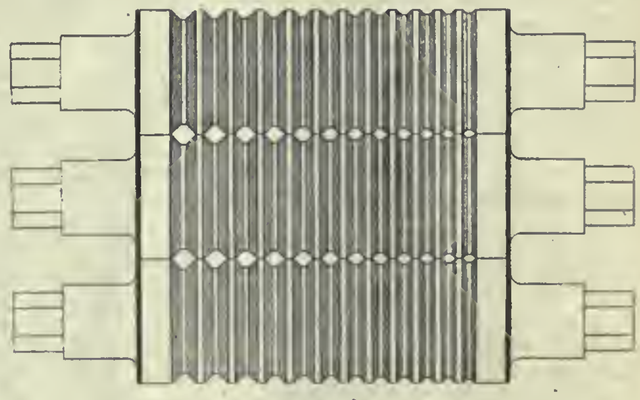

Fig. 4—Depicts the oval rolls. The violent change in section of the metal from a square to an oval aids in making the bar fibrous in nature.

Rolls

From the foregoing it will readily be seen that the heating of iron or steel must not be done too quickly, nor too slowly, if a fine quality of product is desired. It may be thought that as the billets are the same in size and weight, that it would be a very easy matter to heat them all evenly, but although the furnace is supplied with billets of a uniform size and weight, so as to make a lot of bars of the same length, it by no means follows that the heating of any one billet will take the same time as another. The heating of a furnace with

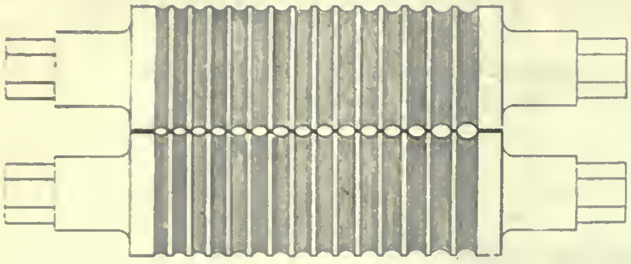

Fig. 3—Strand rolls showing the fillets in the bottoms of the grooves. The fillets make the edges of the bar fibrous in character, which is so essential for strength in iron and steel sections. Being made out o. chilled iron these rolls wear long.

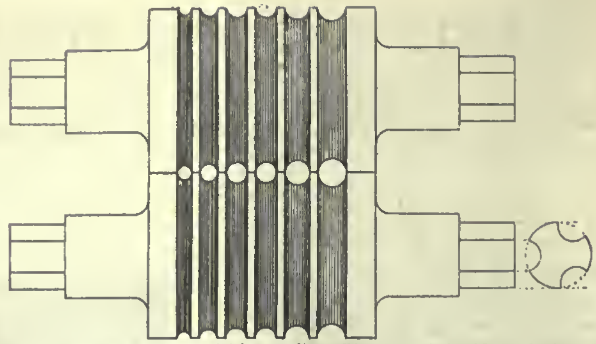

Fig. 5—Illustrates the finishing rolls. The rounded sides of the oval easily conforms to the shape of the round groove. In practice, these rolls are worked with 1-32 of an inch light between their collars, which prevents their delicate edges from breaking. The change in the shape of bar from oval to round also adds to the fibrous nature of the metal.

coal precludes the possibility of securing the even heating of all of the billets at the same time. As a general rule there will be a sufficient number of them hot enough to start the rolling and by the time these are sent to the rolls the others are ready. The train of rolls used to make these 1 1-8 inch steel bars consists of roughers, strands, ovals and guide rounds or finishers. The roughing rolls are three-high and are made out of either cast iron or steel, the latter metal being the best, as it stands rough usage better, it occasionally happening that a pair of tongs will slip out of the rougher's hands and go into the rolls. If they are made out of cast iron a collar will be broken off, thus the set will be idle until a new roll can be turned. If a pair of tongs goes into steel rolls it will be cut in two —the collar edge where it cut the tongs will be dented, which does not prevent the rolls from working. And as it takes a blacksmith about three hours to make a new pair of tongs, while it will consume about one week's time to turn a new roll, it will be seen that the steel roughing rolls are more economical than cast iron ones.

In purchasing steel rolls it is best to get a metal having a high carbon content, as they wear better in the mill and do not bend, besides giving good satisfaction to the users. Following is a chemical analysis of roll steel which is considered "next to the ideal metal by chemists," rolls of this analysis having stood the roughest kind of usage in the mill and lasting long in the housings before requiring dressing in the lathe.

Carbon; combined, .49; silicon, .211; sulphur, .036; phosphorus, .041; manganese, .68.

The type of roughing rolls used in modern mills is the box and edging pass design, illustrated in Fig. 2. Box and edging passes reduce the billet much quicker than the gothic-shaped grooves which were much formerly used. The roughing rolls used to make the round steel bars for rifle barrels are each 10 inches in diameter and 40 inches long, excluding necks and wobbler lengths. They contain a box and edging pass in each roll in addition to the angle grooves, of which there are nine in each roll ranging in size from 2 1-4 inches downwards. For the sake of clearness in the photographs, the full number of angle passes are not shown. The white-hot billet from the furnace goes through the various passes in the roughing rolls until it is reduced to 1½ inches in diameter.

It is then ready for the strand rolls depicted in Fig. 3. Like the roughers, these are three high, each roll being ten inches in diameter. In body length they are 30 inches long, being ten inches shorter than the roughing rolls. Strand rolls are made of chilled iron, so as to give long service in the mill before requiring dressing—as a general rule they will last in the average mill between three and four months before the grooves wear out of shape. They contain the following passes, each one having an angle of 92 degrees. 1 7-16, 1 3-8, 1 5-16, 1 1-4, 1 3-16, 1 1-8, 1 1-8, 1 1-16, 1 1-16, 1 15-16, 7-8, 13-16, and 3-4 inches. It will be observed that there are a number of duplicate passes. These are put in the rolls, so that when one groove wears out another of the same size can be used by the roller; thus allowing the rolls to be in use longer.

As the grooves vary in size by sixteenths, the roller can, by raising the rolls, make a 1 1-2 inch bar in the 1 7-16 inch pass—this method of using the grooves in the strand rolls also allows them to be in use longer before they require dressing in the lathe, money being saved for the firm by this method of handling. The 1 1-2 inch bar from the roughers is taken over to the strand rolls and goes once through the 1 3-8 inch pass and from thence into the 1 1-4 inch strand groove. After going once through this pass the bar is turned over at a right angle and pushed through the same sized pass again, the idea being to have all four corners of the bar with square fillets, all being as perfect as possible, which the double rolling in the one-sized pass secures.

Grooves

By inspection of the strand roll picture it will be seen that the corners of the grooves are not left with a sharp edge, but that they have a small fillet at the bottom. This is done so that the corners (the weakest part of the bar) will be worked as much as possible, so that they will have a uniform strength compared to the rest of the bar, and also keep the grooves in the oval from wearing out rapidly, which would be the case if sharp edged strand bars were used. The bar is now ready for the oval rolls shown in Fig. 4. These are two-high and have the same lengths and diameters as the strands. They are also made of cilled cast iron and wear well. This set contains the following passes, some being duplicate.

One 3-4, one 13-16, two 7-8, two 15-16, three 1 inch, two 1 1-16, two 1 1-8, one 1 3-16, and one 1 1-4 inch pass. The above sizes must not be taken as the actual widths of the grooves, but they are used to designate the size of oval used to make a certain size of round; thus the 1 1-8 inch oval takes its name from the size of round made in the finishing rolls. The strand bar is placed on its side and inserted into the oval groove. This changes the shape of the 1 1-4 inch square bar to an oval one 1 7-16 inches wide by 1 inch thick. There are different styles of oval grooves put in rolls to make round bars—some being very wide and not very thick; others approach the size of the round bar to be made, the thickness being nearly the same diameter as the round, the width being only 3-16 of an inch larger. Such an oval will not cause the finishing grooves to lose their shape as quickly as the sharper and thinner ovals do; therefore, they last longer in the mill before requiring dressing. There is one drawback to the rounder shape of ovals, viz.: They are harder to insert into the round groove, especially when the speed of the engine is high, or when the end of the bar is colder than other parts. The sharper edged ovals enter the round groove very quickly, whether the speed of the engine is high or low. The width of oval used to make the 1 1-8 inch steel bar occupies an intermediate position, it being between the round and sharp edged ones. We now come to the design of the finishing rolls shown in Fig. 5. As this is a 10-inch train of rolls, the guide rounds are also ten inches in diameter, the top roll being one-eighth of an inch larger in diameter, so that the faster peripheral speed of this roll will deliver the finished metal in a straight line.

Like the strands and ovals, these rolls

(Continued on page 515)

Causes of Defects in Steel Ingots

Influence of Casting in Relation to Bar — Bottom Cast Steel — Top Poured Steel — Composition of Slag

By J. N. KILBY

At the September meeting of 1916 and the May meeting of 1917, of the Iron and Steel Institute, papers were presented by the author dealing with defects found in steel ingots or in the article manufactured. Papers upon the same subject have also been read before the Sheffield Society of Engineers and Metallurgists and the Staffordshire Iron and Steel Institute. In this present paper, read before the Iron and Steel Institute and reported in *Engineering*, it is intended to extract some of the matter given in the last two papers, coupled with further observations and results.

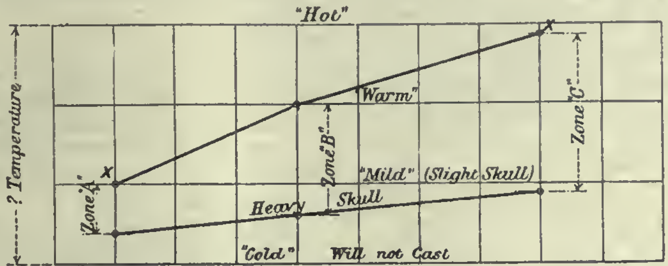

FIG. 1—Zone "A" nozzle 1½ in. Where the ladle running at full stream above capacity of the ingots upon the bed, and the rate of filling depends upon the teemer using the stopper throughout. Zone "B"—Nozzle 1⅛ in. Where the number of ingots per bed is just under the capacity of the ladle, casting at full stream. Zone "C"—Nozzle ⅞ in. Where the nozzle size and the capacity of the ingots on the bed balance when casting full stream, the steel tending to freeze slightly on the surface during filling.

Previous Conclusions Upon Influence of Casting in Relation to Cracks in The Ingot of Bar

It is generally accepted that the important factors are:—

1. Temperature of the steel at casting.
2. Speed with which the mould is filled.

Other yet lesser factors are:—

1. Whether the ingot is bottom or top-poured.
2. Size and weight of the ingot.
3. Cross-sectional area compared with length.
4. Composition of the steel.
5. Weight of steel to be cast from the ladle.

Temperature of the Steel

Different opinions still exist as to the present value of pyrometry in controlling the furnace product. In November last this variance of opinion was obvious at a gathering of experts upon the subject. (Faraday Society. See *Engineering*, November 9, 16 and 23, 1917.) I give here some views upon the matter, which at the least do not agree.

		MINUTES				AVERAGE
A	TIME EACH INGOT	1½	2	2½	3	10%
	DEFECTS AT MILL	20%	10%	5%	3%	
B	TIME EACH INGOT	2	2½	3	3½	5%
	DEFECTS AT MILL	10%	5%	3%	2%	
C	TIME EACH INGOT	3	3½	4	4½	1%
	DEFECTS AT MILL	2	1	RARELY CRACK		

FIG. 2—Showing yield of sound steel free from cracks in rolling to be read with Fig. 1.

Dr. Rogers, in his criticism of my last paper in May, says "that a good deal could be done with the aid of pyrometers, but that he had not found them to be sufficient in themselves, and that his own efforts in the direction of inventing a pyrometer to overcome the limitations were not as yet completely successful."

He further states that "he quite well knew the temperature of the bath, vision also being supplemented in many practical ways; so that control and investigation of the process presented no difficulty in that respect." No doubt a good deal can be done when the temperature of the steel in the furnace can be determined accurately: it is not much that divides, but, unfortunately, it is the mainspring of the whole. High temperature just prior to tapping can be easily be adjusted by additions of scrap.

Mr. Service thought I relied too much upon what he termed "experience and eye method." The opinion of Mr. Service is very interesting when compared with the following extract from Mr. Cosmo Johns' paper, published in *The Iron and Coal Trades Review* for November 16, 1917:—

"It was found that a skilled observer could, with the aid of blue glasses, from observations of the steel as it poured from the furnace into the ladle, estimate differences of possibly 10deg., and certainly 15 deg., apparent temperature; while men, watching the pouring of the steel from the ladle into the moulds, where the increased viscosity, due to decreased temperature and other factors, rendered possible a greater precision in the estimate, could certainly distinguish differences of 10 deg. apparent temperature. Any pyrometer adopted must therefore be capable of giving consistent readings with greater precision than 10 deg. As a matter of fact, a trained observer can, with a suitable instrument, obtain readings with a variation of 2-5 de. under very favorable conditions, and this degree of accuracy is more than sufficient for effective control of the metallurgical processes employed. For each class of steel it is only necessary to determine—for the particular casting method employed—the 'normal' temperature when the steel is tapped from the furnace, which gives the best result. This 'normal' may vary as the process employed is modified. The measurements involved are therefore divergences from the particular 'normal' adopted at the time, and as the range of variation in regular practice is small, no appreciable error is introduced by considering the differences in the pyrometer reading as temperature differences. The desirable temperature varies 10 deg. apparent from the normal, and a very high percentage of the casts does not appreciably exceed these limits. Temperature variations of 20 deg. apparent give rise to serious difficulties, and 15 deg. apparent can be considered to be the variation admitted in practice. These limits are for special steels; they are wider for ordinary commercial steels."

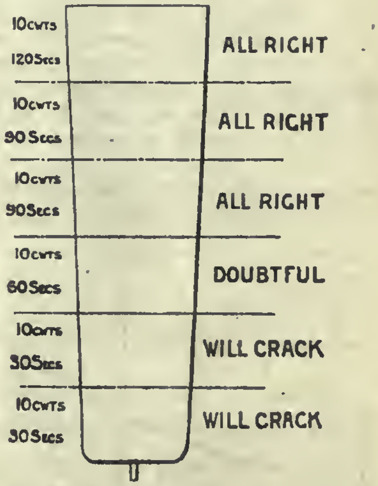

FIG. 3—3-ton ingot to be cut up for tire blocks. Total teeming time, 7 minutes. Top half, passable, bottom half sure to crack. (Where nozzle full stream exceeds capacity of ingot). As shown the time varies for each 10 cwt. portion and would result in defects according to the time taken for each portion.

A statement by Dr. W. Hatfield on "pyrometers from the Standpoint of Ferrous Metallurgy," published in *The Iron and Coal Trades Review* for November 9 of last year, may be of interest at this point:—

"Although the temperature at which steels are cast must have an influence upon their ultimate physical properties, no ready or really reliable method for measuring such temperatures from the works standpoint is available. This is a considered statement. It would obviously be of considerable use if the temperatures of successive heats could be controlled and determined."

When one speaks of casting temperatures, the terms hot or mild are purely relative to the product desired, though they are often used without full regard to accuracy. For instance, a cast alleged to be on the "hot" side may produce ingots free from cracks, provided the period of filling be prolonged to the correct extent by using correct-sized nozzles, or secondary ladles, or, when bottoming casting, putting down a sufficiently large number of ingot moulds per bed. Further, a cast alleged to be on the cool side will most certainly yield ingots which will crack at cogging, if they have been teemed relatively quickly. Teeming speed is really of greater importance than temperature, taking the variation from one cast to another to be within usual everyday practice, and omitting exceptional cases of hot steel caused by careless manipulation.

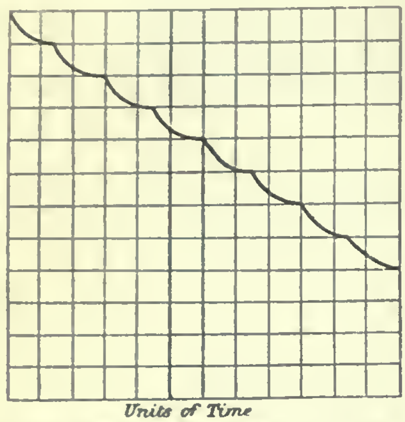

FIG. 4A—Where insufficient Ca O or no Ca O is used. Showing erratic fall in carbon and consequent variable condition at finishing.

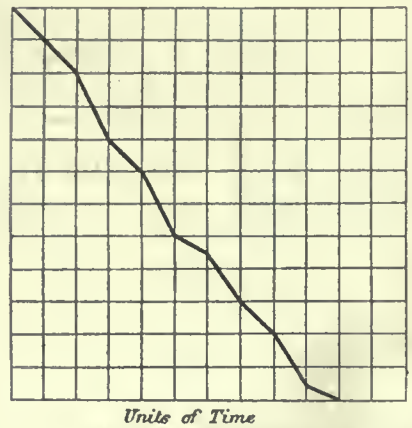

FIG. 4B—Where the slag contains the correct Ca O per cent. Showing correct bath conditions at any period of the boil.

Of all trades and processes the steel trade stands first in it dependency upon the personal equation and the whole business appears to be one compromise after another. The only direction in which we can work is to avoid all unnecessary complications, and to provide methods possessing the widest margin of safety.

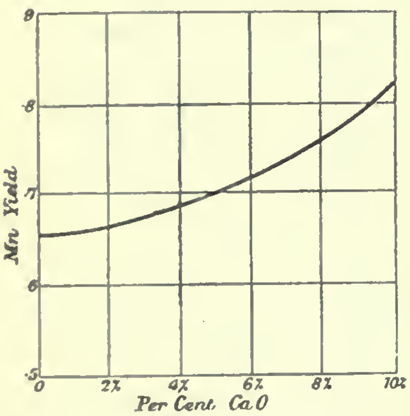

FIG. 5—To show relationship between Mn. yield into the steel and the percentage of Ca O in the slag all varying factors, of course, being considered.

Argument upon casting temperatures would lead one to suppose that the difference in degrees of heat was extremely great. Experience proves that this difference, coupled with the factor of safety is not great. The casting of heat after heat with a slight skull left behind, at the same time getting cracked ingots in the mill or forge, points to the great importance of correct teeming speed per ingot. Speaking of casting temperatures and skulls, a case occurs to my mind of the principal of a firm who insisted upon the necessity of cool steel, asking for confirmatory evidence in the form of a certain minimum weight of skull (5 cwt.) each time. After numerous too successful attempts at the weight desired (very often resulting in the loss of the entire cast) someone discovered that, by ramming or bricking the ladle bottom in a direction sloping away from the nozzle, a skull of consistent weight could be obtained every time, even on the warmest of casts, but all casts were thereafter accepted as cool.

Bottom Cast Steel

The objects achieved by bottom casting are:

1. Better surface of ingot.
2. Less splash.
3. Freedom from cracks during working.

The first two items are generally obtained, but the third is dependent upon factors already detailed. There are a great many objections to the bottom casting of steel, the danger of the extraneous inclusions being far greater than is the case in top casting.

It is possible to cast group of ingots from the same heat and have a number of them work well while others will be very badly cracked.

It will be seen that casting through varying sized nozzles, or varying weight per bed, one may easily obtain great differences in the actual time required to fill each ingot. The time factor governs the first formation of solid steel, and decides whether the later contraction will crack the ingot or not. The steel should not fill the mould in too free a manner, but should tend to scum over and gradually and evenly form a thin cover of semi-solid steel from the bottom to the top as the filling proceeds.

If one casts a charge steel in the following manner:

1st bed ....6 ingots.
2nd bed ....5 ingots.
3rd bed ....4 ingots.
4th bed ....3 ingots.
5th bed ....2 ingots.

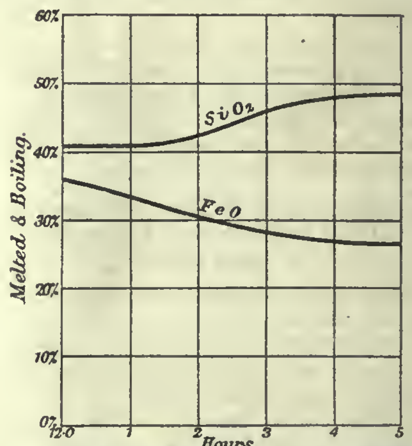
with a similar stream from the ladle in each case, the result would give a variation in percentages of defects to the proportion of increase of the speed with which the moulds filled (see Figs. 1 and 2). Cheese tires amply prove this, e.g., I found that in casting 480-lb. cheese tyres the percentages of defects were as follows:

Minutes.

¾......All cracked under pressure.
1 ......50% cracked under press.
1¼......25% cracked under press.
1½...... 5% cracked under press.
1¾...... 2% cracked under press.
2 and over..None.

Again, with regard to tyre steel, where ingots are sliced into blocks and afterwards, etc., varying results may be obtained upon the self-same ingot, due to erratic teeming, as indicated by Fig. 3.

Regarding the base of bottom portion of any bottom-poured ingot (where a good percentage of defects will show, if visible anywhere), it is important not to rush the first foot of the ingot during teeming.



TIME	FEEDS			CARBON	SILICON	TIME	FEEDS			CARBON	SILICON
	ORE	LIMESTONE	PIG IRON	BATH SAMPLES			ORE	LIME	PIG	BATH SAMPLES	
12·0	–	–	–	1·00	·010	2·30	–	5 CWT.	5 CWT.	·26	·030

To show bad case of over-oxidised charge during melting. Also conditions subsequently and analysis of steel, etc.

Variation in the teeming speed either in the individual groups of ingots, in a cast, or from one cast to another, is therefore to be brought to a minimum. There is a definite time per ton for any mould; above this time no cracks result, but below it trouble begins, in spite of "cool" steel.

From the foregoing remarks relative to bottom-cast steel, the logical conclusions to be deduced are: That the pitman must be in such a position that he cannot possibly teem too quickly, and that the speed must be such as to be safe,

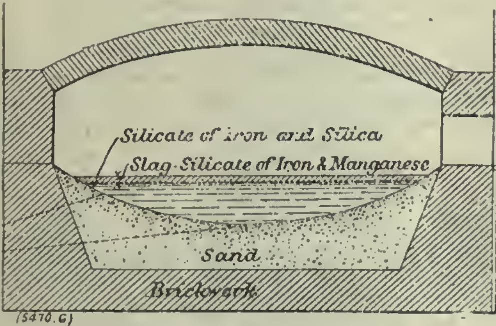

FIG. 7—Section of acid lined furnace.

yet so regulated that the cast can be successfully dealt with. Where slow teeming depends entirely upon stopper manipulation erratic results are certain.

Top-Poured Steel

Certain classes of steel are cast to advantage by being top poured.

Such material is always freer from extraneous inclusions and shows fewer defects from this cause when the ultimate article has to be machined and closely scrutinized. The compensating disadvantage, however, of top pouring steel is the greater liability of obtaining cracked ingots. In many cases no regard is paid to the actual time in filing the moulds or finding the speed most conducive to correct results.

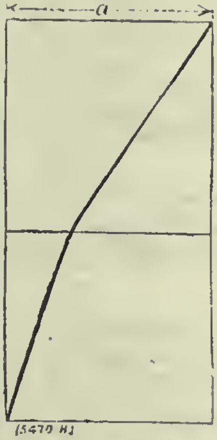
Speed in filling the mould is the most important factor at any time in the process of steel-making. Provided that the speed of a top-poured ingot compares equally with a bottom-poured one, similar in size, corresponding results can be obtained as far as freedom from cracks or rokes is concerned. When top pouring, the flow of the steel tends to force any particles of extraneous matter to the sides of the ingot, thus making a purely surface defect, as compared with an embedded one in the case of bottoming pouring. When taking teeming times the period should commence from the moment the steel enters the mould to the instant that "feeding," as it is termed, takes place. Two ingots may be teemed, the total time being equally divided between them, yet one may be sound and the other work badly; the reason for this being that the time taken by the latter may have been spent, not in casting the ingot proper, but in feeding the last portion. The smaller the ingot the greater the comparative necessity of top pouring correctly.

It is somewhat striking to note the differences one finds in teeming speeds, for a given weight, at different works. For the same quality of steel in a 65-cwt. ingot, teeming times varying from 1 minute up to 10 minutes for the whole ingot have been noted.

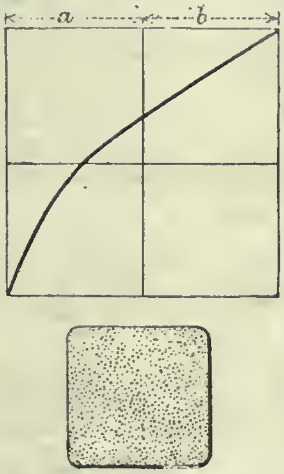
Dr. Burgess, in his communication on Brearley's paper,* gives his time for teeming a 7,200-lb. ingot as 1 minute. Taking a similar ingot my experience is that, when teemed under 3 minutes, 80 per cent. will show cracks at rolling, the safety line actually being 6 minutes.

should the steel be so cool as to lap badly, the chances are much against the mould filling at all.

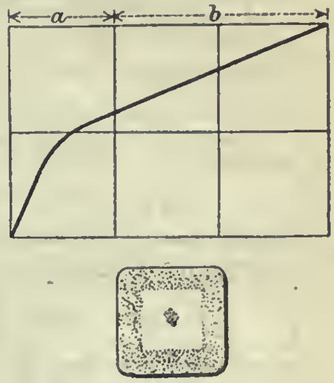
Chrome, high silicon and vanadium steel are always subject to lappiness in a greater or less degree. The appearance of the ingot will give some idea whether this lappiness is going to be a serious defect or not. If the teeming is so slow as to allow the steel to form a solid cake or cover, through which it afterwards bursts (and this frequently occurs in this class of steel), the result will be sufficiently serious to attract notice later when machining. The formation of oxide films on the surface of such slowly cast ingots tends to give fine elongated seams or pockets when the steel is rolled. The use of pitch, ground as fine as flour, in the mould as the steel arises, must necessarily help to minimize the danger, as also the tarring of the mould. An ingot scumming over too quickly will clean itself with a minute proportion of



Cheese tire ingot where the entire ingot is solidified by direct cooling of the mould itself. Inclusions finely disseminated.



10" square ingot. Where a large portion of the ingot is chilled. Inclusions fairly well distributed.



14" square ingot, where about one-third of the ingot is chilled. The dotted area in small bars from the ingots show where inclusions would be located.

FIGS. 8, 9 AND 10—"A" shows proportion of ingot solidified by chilling effect of the mould; "B" shows proportion solidified by radiation. The curves show the rate of solidification of the whole ingot. The slag particles are fairly evenly distributed in the chilled area but are found more locally in the more slowly solidified steel.

Lappiness

Bottom-poured steel cast at too low a temperature or too slow a speed tends to cause lappiness or folds, in the ingot. Ordinary carbon steels do not suffer much from this condition for the reason that, such pitch.† It is evident, therefore, that in the case of some steels there is a minimum rate below which the teeming must not drop.

The use of comparatively large nozzles in the ladle and a small weight per bed lead to what I term spasmodic teeming, the stream from the ladle running at full force being of greater volume than is compatible with the correct filling of the moulds. In these cases the teemer has to use his discretion and endeavor to control the stream so as to fill the moulds correctly. Often the result is an ingot teemed in widely varying speeds and lapped in a good many places, the stream being often momentarily cut off.

Composition of Slags of the Different Steel-Making Processes, Their Physical State, and Relationship to the Ultimate Product

Acid Open Hearth.—In the May paper of 1917 a number of charts were given with certain facts illustrating the effect of lime upon slag composition and the

No. 1—Section of basic open hearth steel showing unsoundness due to suitable conditions of slag and bath at tapping.

No. 2—Section of electric steel ingot showing (1) blowholes (wild steel); (2) lappiness, or folds in the ingot; (3) included unfluxed fire clay.

resultant physical conditions of the acid open-hearth process. It was my argument, based upon analyses and records, obtained from different works, and extending over a period of more than ten years, that the use of limestone or similarly constituted basic material was highly essential to the success of the process. That, with a slag containing certain percentages of lime, the danger of slag inclusion resulting from retained oxides, silicates, etc., was to a large extent minimized, at any rate, as far as furnace control could go. Further, that this was brought about by the lime slag

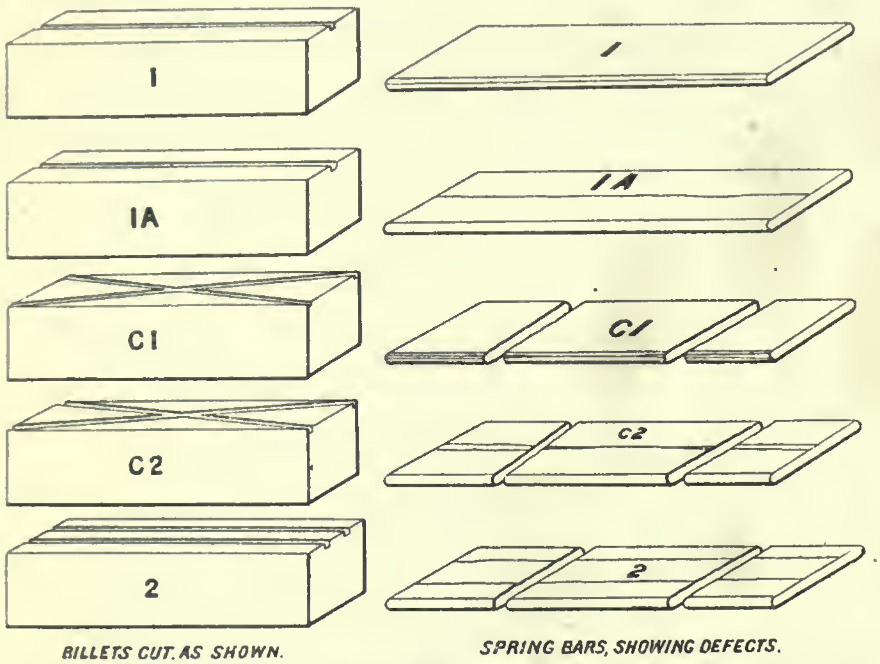


FIG. 11—To show 4 in. by 3 in. billets cut where marked to a depth of ¼ in. and afterwards rolled to show how defect developes. To illustrate effect of rocky billets

being in a perfect state of flux, thus yielding more intimate contact with the steel, and a state of receptivity for such undesirable inclusions referred to. Reference was also made to the control of carbon elimination.

Fig. 4 shows two diagrams, A and B:

(A) Charge worked throughout without CaO.

(B) Charge worked throughout with CaO.

In the top diagram (the charge without CaO) it will be noted that the fall in carbon is erratic and for a given time varies greatly. The bath at any stage would not be in a reliable condition, and naturally such heats usually vary in the finish results as far as analysis goes, apart from the other and greater evil of doubtful steel. In the bottom diagram where CaO has been introduced from the beginning and maintained throughout the process, the carbon elimination is more regular, and a charge could be tapped almost at any period without fear of very wrong results analytically. Consistent results from finishing material added are more readily obtained. Where large losses of manganese take place at the finishing stages, one may suspect bad cases of the trouble in question, viz., slag inclusions. The influence of CaO upon the manganese yield is very marked. Including all variables, particularly the time factor, and basing the figures given upon data extending over a huge number of casts, the relationship may be described thus:

The yield of manganese obtained in the steel in the bath, from added ferro-alloys, all variables considered, is proportionate to the CaO per cent. (or its equivalent of similar basic material) in the slag. See Fig. 4A or Fig. 5

It will be noted in Fig. 5 that the manganese yield obtained increases with the CaO per cent. in the slag. The curve is derived from the results of average casts, with varying CaO per cent. The difference as shown is immediate decrease of FeO in the slag immediate decrease of FeO in the slag, produce a more absorbent medium for any extraneous matter present in the steel.

4. That CaO is not added to thin the slag.

The elimination of any element or compound impurity from the metal into the slag or flux of almost any metallurgical refining process depends upon:—

(A) Temperature.

(B) The receptivity of such slag or flux for such impurity.

Furthermore, the last traces of impurity are usually most difficult of removal Consider for a moment, that in the case of particles of included matter in the steel, the loss of defective material through this cause is, comparatively speaking, only a very small proportion by weight. In the case of the acid open-hearth also let us consider that we are trying to remove traces of compounds somewhat similarly constituted chemically, to the envelope by which the molten metal is surrounded. Reference is made here to the sectional diagram of the acid open-hearth bath (Fig. 7.) When new, the hearth proper is composed, or should be composed, of semi-fused SiO_2 plus small percentages of oxides of alumina and iron. This assumes before charging the appearance of an almost white semi-glassy mass. In this condition it is in a highly absorbent state, and continues to take from the charge a large amount of oxides (not metallic matter) until the bottom becomes satisfied or completely impregnated. By this means the hearth becomes a most important source of influence upon the working of the steel and its ultimate composition, and possesses some relationship to certain classes of defects. There is a stage, usually after the first few heats, when the hearth, satisfied with oxides, reverses to some degree the action, relieving minute particles of non-metallic matter which are taken into the steel. The elimination of any such matter can only be effected through the absorbing properties of the slag, at least in so far as furnace operations are concerned. The composition of the slag, and its physical state, must therefore be so constituted as to aim at this desired and necessary form.

Thus far I have dealt with oxides formed during melting or introduced during boiling, and their possible elimination, by means of the slag influence upon them. Under good conditions, however, an appreciable residual amount not removable in the furnace remains in the steel. Commercially we may have steels termed free from the evil, which in point of fact are not. The amount present in such instances is insufficient to affect tests, or the speed of solidification and size of the ingots and the requirements of the manufactured article do not reveal, but tend to hide its presence. Small ingots retain the inclusion disseminated fairly evenly throughout the mass, the chilling effect of the mould preventing liquation of the particles. In the case of large ingots the reverse is experienced. A cheese tire ingot, for example, is subject to what I may term direct chilling solidification, or in other words, the mould influence outweighs the heat

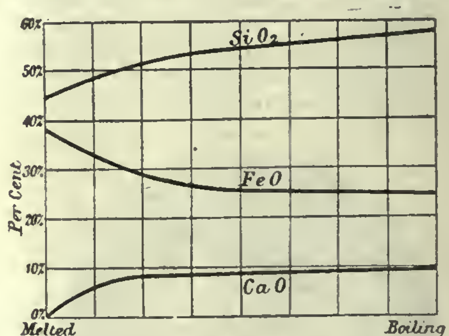

FIG. 12—Showing how addition of Ca O during period of melting to boiling influences slag composition.

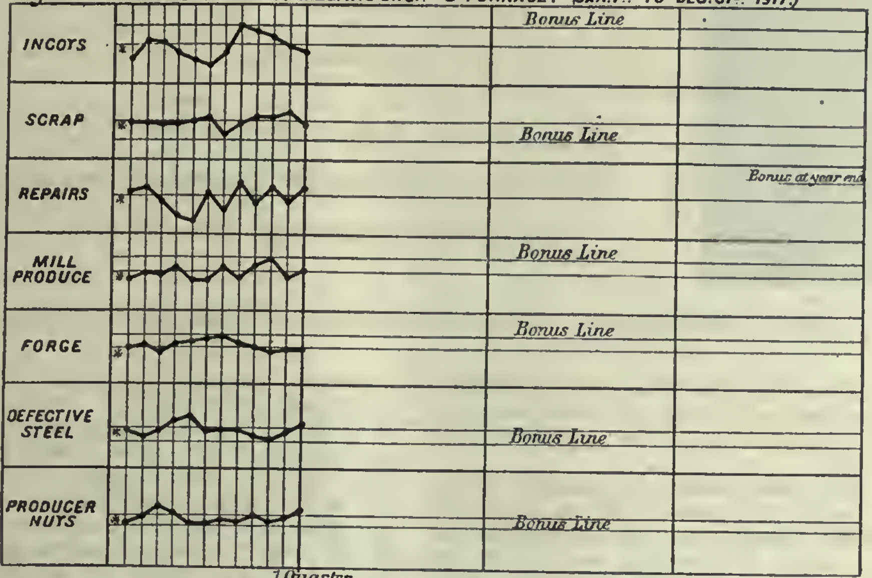
above freezing-point possessed by the steel in the mould. Taking such an ingot, weighing only a few hundred-weights, and comparing it with one weighing about 25 tons, the actual time of solidification in the former case is in minutes, and in the latter many hours. We find therefore that weight and cross-sectional arena of the ingots have their own particular influences upon the locality of the inclusions. See Figs. 8, 9 and 10.

The article to be manufactured and the processes through which it passes

Fig. 13. YIELD & COST CHART. MELTING SHOP D FURNACE. (JAN. 1ST TO DEC. 31ST 1917.)



(5470 L) *Average for previous year or what is expected as minimum

To bring a closer relationship between melting shop, mill and forge, and to bring home defective material. Also to formulate a bonus system to increase output and quality, giving the steel-makers an interest beyond the ingot.

are important points bearing upon the subject. With small forgings or stampings in special steels, or highest grade wire, every few pounds of the whole cast is put practically to close physical and other tests, whilst close machining also tends to reveal defects of minute proportions yet sufficient to cause rejection and failure. The inevitable residual slag inclusions found in the ingot and not removable in the furnace present a difficulty worthy of overcoming. To cast the steel in such a manner as to bring the whole in direct contact with some absorbent flux either in the ladle or a secondary ladle, or in the mould, would possibly prove a successful course. Some essential basic fluxes have great affinity for oxides and silicates of iron, manganese, and aluminium, and the contact of the steel with such during the process of casting would certainly be at the least partially successful. It will be often noted, when casting steel by the tundish method, that a good deal of extraneous matter rises to the surface of the steel, due to giving up of matter previously held in suspension. The experiments made in the direction named do not warrant more on the subject at present, but certainly give incentive to more investigation.

Basic Open-Hearth Steel, With Some Reference to the Electric Process

During the last three years particularly the growth of the electric process of steel making has been nothing less than phenomenal. No one can dispute that the electric process can produce material easily, which in our acid or basic open-hearth would present considerable difficulty.

Of the many claims of the process, freedom from slag or gases has been most prominent. Correct manipulation will most probably justify this claim, but material is sometimes made which, as regards defect, rivals that by any other process. This defective material has been obtained naturally by wrong manipulation and the non-fulfilment of the priciples of sound steel-making, and the fault is not attributable therefore to the process.

The defects from which our basic open-hearth steel suffers are due to similar causes in the case of the electric process. That high-grade material can be made and is made on the basic hearth is undoubtedly correct. Numbers of otherwise practical men couple thoughts of basic steel with the inseparable phosphate slag, which has perhaps been the main obstruction to producing sound high-grade steel. A good many of the claims of the electric basic furnace apply equally as well to basic open-hearth. The main difference in the two processes, ignoring certain mechanical advantages, is the quick supply of local intense heat in the electric furnace. The physical state and chemical composition of the slag in a basic open-hearth process are the main essentials for success. Giving full appreciation to the valuable work done in this country by Mr. E. H. Saniter and other eminent metallurgists, in working out the process as a formidable competitor of the acid open-hearth, little has been done in establishing its position in the industry as far as special and alloy steels are concerned. The failure of the material is not due to the process, but to incomplete exploitation or faulty manipulation.

If the basic open-hearth process is worked with highly phosphoric raw material direct, and with one slag only, it will not prove to be a serious rival of the other processes in the special steel trades. I may be told that the particular advantage is in its adaptability to the use of almost any class of raw material. I maintain that the load (if I may use the term) of the working of the charge is in ratio to the phosphorus content; and that the means necessary for its removal constitute the first source of danger in the way of poor material. Charges relatively high in phosphorus have to be more than liberally dosed with oxide to effect elimination of that element, leaving behind in the steel the undesirable oxides producing the defect as shown in photograph No. 1.

*Journal of the Iron and Steel Institute, 1916, No. II., page 180.

†The use of anthracite for this purpose is fraught with great danger and should never be resorted to.

INTERESTING EXPERIMENTS

Proof of Earth's Revolution Can Be Obtained With Bowl

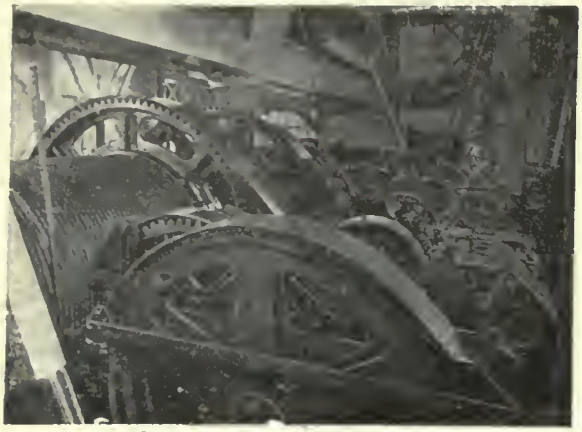
Take a good-sized bowl, fill it nearly full of water, and place it upon the floor of a room which is not exposed to shaking or jarring from the street. Sprinkle over the surface of the water a coating of lycopodium powder, which can be obtained at almost any chemist. Then upon the surface of this coating of powder make, with powdered charcoal a straight black line, say an inch or two in length.

Having made this little mark with the charcoal powder on the surface of the contents of the bowl, lay down upon the floor close to the bowl a stick or some other straight object, so that it will be exactly parallel with the mark. If the line happens to be parallel with a crack in the floor, or with any stationary object in the room, this will serve as well.

Leave the bowl undisturbed for a few hours, and then observe the position of the black mark with reference to the object with which it was parallel. It will be found to have moved in the direction opposite to that of the movement of the earth on its axis. The earth is simply revolving, has carried the water and everything else in the bowl round with it, but the powder on the surface has been left behind a little.

The line will always be found to have moved from east to west, which is perfectly good proof that everything else has moved the other way.

The Union Engine and Machine Works, Ltd., Montreal, has been incorporated with a capital stock of $300,000 by Walter R L. Shanks, Francis G. Bush, George R. Drennan and others, to manufacture machinery, tools, engines, etc.



60 H.P. motors and hoist drums.

LARGE AMERICAN NAVY CRANE AT PANAMA

Regenerative Breaking and Safety Devices Make Electrically-Operated Crane Safe From Operating Standpoint

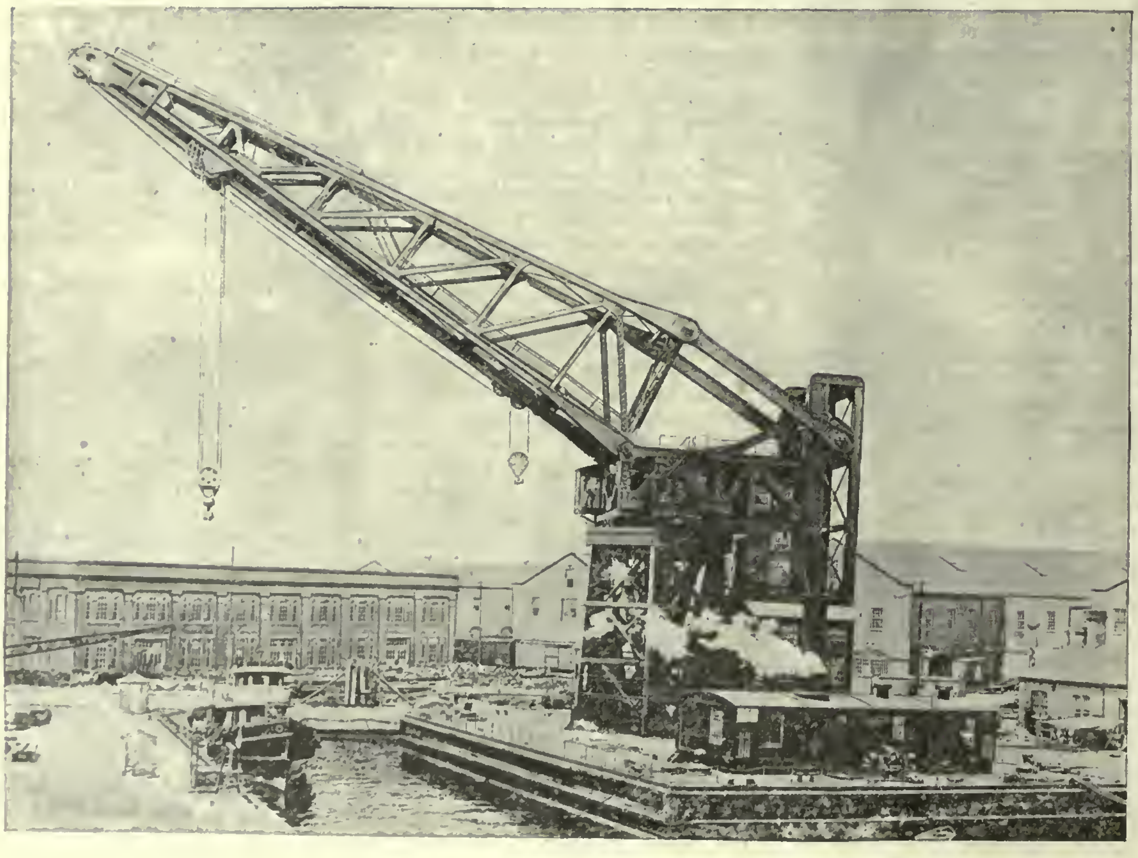
FLOATING cranes generally are of the bridge type and when operating the whole crane including the pontoon is manœuvered to bring the hoisting cables to the proper position for lifting. The one illustrated is of a revolving type and it operates on the principle similar to that of the ordinary derrick.

To give a concrete idea of the amount of work this apparatus can accomplish it may be said that its capacity is equivalent to the weight of 100 of the largest touring cars. The lifting hooks weigh about two tons, or the equivalent of a large touring car. When the jib is raised to its maximum height it is over 200 feet above the water level, a height greater than that of an 18 story building. As previously stated the whole structure is mounted on a flatboat, or floating pontoon.

The boat contains a complete boiler plant, and an engine driven generation which supplies the electric current for operating the various motions of the crane, which are controlled from a small house mounted high above the deck. By the means of a few levers and master controllers one operator is able to control all the functions with the utmost delicacy.

The speed can always be controlled by the means of the electrical mechanism of the crane. When heavy loads are lowered the motors are turned into generators and thus the speed is controlled with great accuracy. In the case of an accidental interruption of electric current, all of the crane's motions are automatically locked by means of brakes, and so ensure the impossibility of dropping the load. Safety and accuracy are essential, as the crane is used to handle large guns and turrets on battleships, and if through carelessness or inaccuracy these should be damaged, it would mean a loss of hundreds of thousands of dollars.

The illustration (Figure 2) shows the first work which the crane did. The navy tug "Massasoit" was suddenly sunk in one of the harbors. After divers had passed the necessary cables under the



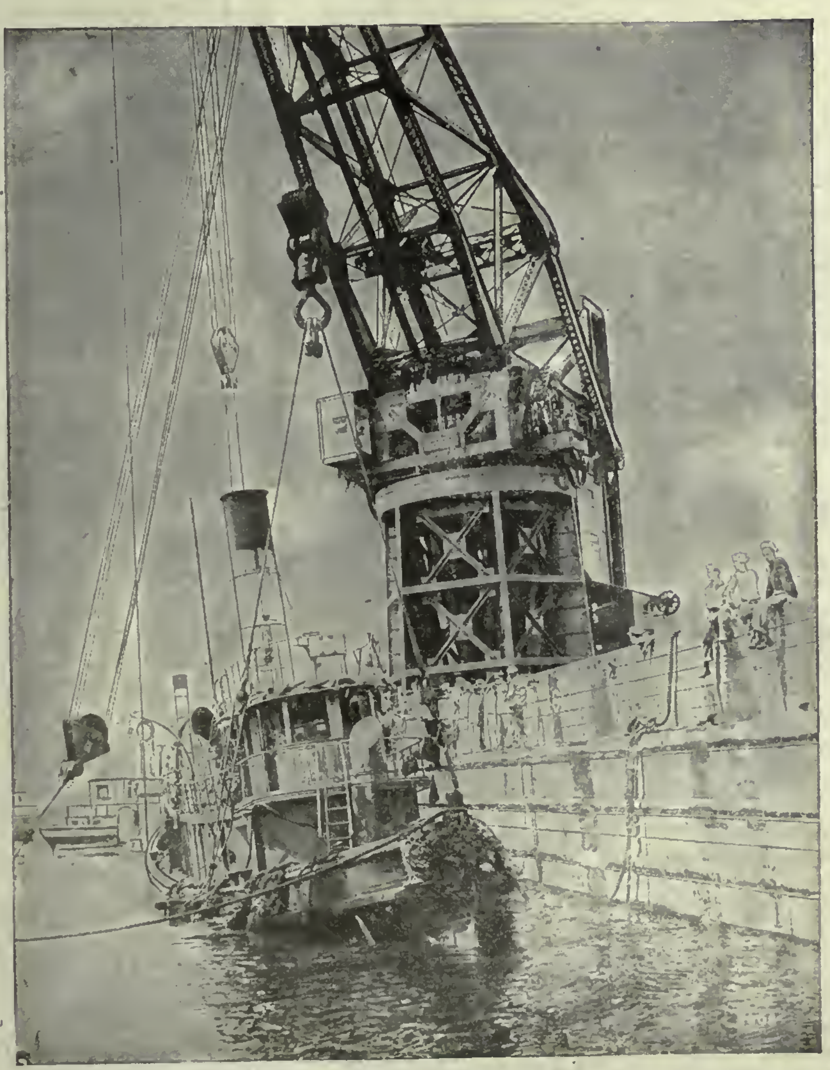
GENERAL VIEW OF PONTOON CRANE

tug, the crane rapidly and quickly lifted it to the surface as shown. Westinghouse motors driving the hoisting drums are shown in Figure 3.

It might be interesting to add that the Panama Canal Commission purchased two similar large cranes for heavy work. The cranes were purchased from a German corporation, but when the test load was applied (which was the same as applied to the crane shown in the illustration) it didn't pass muster. The first collapsed and was wrecked owing to a faulty design of structure.

The following data will give a good idea of the size of this machine. Size of pontoon, 140 ft. long by 85 ft. wide and 15 ft. deep, size of engine generator set, 150 KW; the crane has a main hoist consisting of two books of 75 tons, each fixed on the jib; an auxiliary hoist of 25 tons capacity movable up and down on the boom; the crane rotates in a complete circle, the rotating being controlled by two 60-HP motors; the boom luffs up and down from a practically vertical position to an angle of about 30 degrees from the horizontal in its lowest position; the luffing is accomplished by two 10-inch screws operated by two 60-HP motors; the main hoists can operate separately or simultaneously, as desired; when lifting the maximum load it is operated by two 60-HP Westinghouse type MC motors; the auxiliary hoist has separate motors for hoisting and trolleying, each of which is 60-HP, the counter-balance at the rear end of the crane is fixed, and amounts to 600,000 pounds; the total weight of the pontoon crane (displacement) is 5,000,000 pounds; the capstans are electrically driven, four in number, one at each corner of pontoon; the anchor hoists are steam driven, two in number, one at each end. The main pivotal bearing, or step bearing supports a ball or universal joint, and carries a maximum load of 2,021,000 pounds; the speed of the main hoist under maximum load is about 6 ft. per minute; the speed of the auxiliary hoist is 30 ft. per minute; the speed of the rotation is one revolution in four minutes; speed of luffing boom, entire range 12 minutes. The boom is of the cantilever type.

The Beach Foundry Company, Ottawa, Ont., is planning to expend about $75,000 on the erection of plant additions.



150-TON REVOLVING CRANE, RAISING SUNKEN TUG MASSASOIT

COURTS PERMIT SHIPS TO INSTALL WIRELESS

Ruling Means That War Urgency Is Greatest Thing At Present

MONTREAL.—Mr. Justice Bruneau dismissed the petition of the Marconi Wireless Telegraph Company, which asked the Superior Court to grant the issue of an interlocutory injunction to restrain the Canadian Car and Foundry Company, Limited, from installing certain apparatus for wireless telegraphy in ships under construction for the French Government at Port Arthur and elsewhere in the Dominion. To grant the injunction at the present time, in view of the facts that the ships are needed for purposes connected with the war would be against policy, his Lordship said: "The French Government wants these ships," he said. "It is a question of urgency. Any interference by this court in the manner asked would delay construction, equipment, and delivery of the ships. The respondents may be made to account for what they have done—but later on, after the war. To grant this injunction would be, in my opinion, not only a great political mistake, but nothing less than a crime against the French Government, without doing any practical good to the petitioner."

General Motors To Build. The General Motors Company, of Pittsburgh will build a $50,000 brick motor truck factory at London, Ont. Work is to commence shortly.

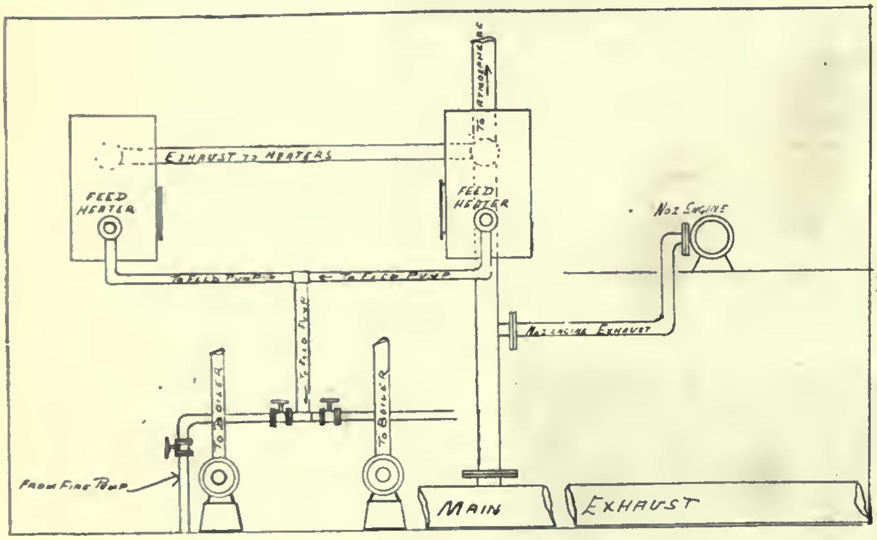
Plant Nearing Completion.—The new plant of the Lyall Construction Co., which is being erected in the east end of Montreal for the purpose of taking care of the big American order placed with the company some time ago, is nearing completion, and will be ready for operation in about a fortnight's time.

Hamilton Short of Gas. The gas shortage in Hamilton during the coming winter will be just as acute as it was last year. This was stated by E. S. Estlin, gas commissioner for Ontario, who was making an investigation for the Ontario Railway Board. Mr. Estlin urged that all citizens be asked to conserve gas to the greatest possible extent. He contended that those using it in furnaces were the worst offenders and would have to realize that conservation was absolutely essential. Mr. Estlin has made a survey of the number of industrial plants and business places using gas from the Selkirk fields and he found that there were 60. These had not yet been put on permits but this step would be taken at once, he stated. There are 150 applications for gas now on file at the office of the United Gas and Fuel Company, Hamilton. New consumers will not be taken on. Mr. Estlin instructed Mr. Byrnes that under no consideration would more consumers be added.

A DAY OF REST? IN THE POWER PLANT

By T. H. FENNER

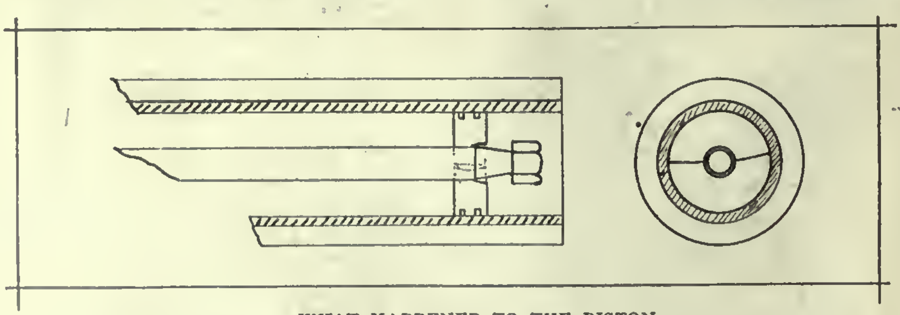
A SERIOUS and expensive breakdown occured to an 11"×9"× 14" high speed tandem compound engine under my charge in a peculiar manner. The accident occurred on a Sunday, when the regular engine room attendant was not on duty. As a matter of fact, no one was in the engine room at the time, the fireman on duty in the boiler room being under orders to come up and look at the oiling arrangements from time to time. To understand what happened we must have a glance at the boiler room, where the cause of the accident originated.



PIPING LAYOUT

The feed pumps took their water from overhead open heaters, of the Webster type, discharging through economiser to boilers. There was also a direct discharge to main feed leader direct, by passing the economiser, and also a direct discharge to an auxiliary header, as shown. The suction pipe from heaters to pump came down to a T between the two pumps, and branched off to each pump. There were also two independent suctions on each pump connected to hot and cold wells. On one of these suctions a connection had been made from the discharge of the fire pump for washing out boilers, and an emergency boiler feed. A branch was tapped off the auxiliary header at each boiler to connect tbe valve of the turbine hose for washing out. When washing out the fire pump was used, discharging through the feed pump suction, through the pump, and auxiliary header. The boiler room staff had stringent orders never to touch this fire pump valve, the engineer on duty in the power house being the only one authorised to make the connection. The reason for this care was apparent, as if the valve from the fire pump was opened and the suction from the open heater left open at the same time, the discharge from the fire pump would have clear access to the heater and from this to the whole exhaust system.

The day that the accident happened being a Sunday, in the ordinary course of events nothing would have been running. However a 50 h.p. armature had burned out on the Saturday morning, and the millwrights and electricians had been working Saturday afternoon and Sunday morning and were ready to try the motor after dinner Sunday. This would mean, if the repairs were O.K., about ten minutes running. Being anxious to know if everything would be alright for Monday morning, I decided to go down to the factory myself. The regular day engineer had been instructed to come in after dinner to run the engine as required, but as he had not shown up I started up myself, made the switchboard connections, and saw that the forced lubrication was alright. I told the fireman where I was going, and warned him to come up at intervals of not more than ten minutes, and look at the engine. I expected to be all through before he came up twice. However, some minor troubles developed in connection with the motor and shafting. A man was sent over to the engine room to see how things were and he reported everything alright. We got ready to start the motor again, and it started up this time perfectly, but after running about five minutes the motor started to slow down and the lights to dim. I started for the engine room on the run, but about half way there was met by the fireman, who informed me in quite a disinterested way that No. 1 engine had "gone to h—." He also volunteered the information that there was a lot of water in the basement. Arriving in the engine room, I saw a tangle of oil pipes, and the broken crank case lying on the floor, and at the same moment an ominous cracking broke on my ears. Coupling this with the fireman's statement of the leak in the basement, I made a rush for the feed pump, finding what I expected, the valve from the fire pump open, and the heaters and exhaust system flooded. The leak in the basement was the excessive overflow from the heaters backing up the water seal from the sewer. The next thing was to look at the water gauge to find the water just bibbing in the bottom nuts of the glasses on the two boilers that were working. I began to reconstruct things a bit in my mind, and then proceeded to catechise that picture of injured innocence, the fireman. The evidence being so complete, he could not deny opening the valves, but hedged a bit about the reason. However, I had a good idea of that, too, and on putting it up to him, he admitted the soft impeachment. He began the course of events by neglecting to watch his gauge glass, and when he did look, found the glass full, but how much more he knew not. However, he promptly stopped the feed pump, neglecting to shut the checks on the boilers. He then resumed his paper, being anxious to see how Foch was making out. Presumably he found the news to his liking, for when he next looked the water was about half glass. He congratulated himself on his excellent judgment in stopping the pump, and thought it would be all right now to start it up again. Here he struck a snag. The boiler checks not being dead tight, when the pump stopped some leakage occurred from boiler to pumps, resulting after a while in the pumps and heaters getting good and hot, too hot to handle water. Deciding that here again was a case for a good man to use his own judgment, he decided to pump some water through from the fire pumps, achieving the double purpose of feeding the boilers and cooling off the lines and pumps. He started up the fire pump, opened the discharge through the feed pumps, and left the main suction open. The water in the boilers did not rise, but it did somewhere



WHAT HAPPENED TO THE PISTON

else, and his ears were soon assailed by numerous strange noises. At the same time his gauge glass lamps started to lose their brilliancy, and it crept into his mind that something was wrong. He went up to the engine room just in time to hear a crash, and had then decided to go and get advice. His view of the matter was that it was decidedly unjust to spoil any poor man's Sunday by involving him in a series of untoward happenings that kept him in a state of nervous tension. Not having time to discuss the matter fully I went to ascertain the damage. I found both the crank pin and crosshead gib straps sheared off, the brasses themselves broken in several pieces, and all the oil piping twisted and broken. The cast iron crank case was also broken, though this was a detail. This was the outer damage. Next thing was to look for the internal troubles. The H. P. cover was removed and an attempt was made to move the piston ahead.. It was apparent at once that something was jammed, and jammed hard, as the hammer rebounded as though from an anvil. It was decided to take the nut off the end of the rod, and a spanner was brought for the purpose, but at the first application the end of the rod and the nut came away together, and it was evident that the rod had been ready to break. We then found that the piston came off the taper surprisingly easy, and after removing the piston from the rod a tentative tap with a hammer was tried on the end of the rod with the same result as before. The next step was to open up the L. P., and this achieved, the trouble was at once evident. The L. P. piston was cracked across, the crack being open from ⅛ in. to 3-16 in., and the piston had been forced over the taper into the parallel part of the rod, jamming on the walls of the cylinder. The only way it could be removed was to drill holes all round the boss and break a piece out, letting the piston come down on the rod, and relieving the pressure. The piston was then taken out in halves. The repairs necessary were new piston rod, new low pressure piston, new connecting rod end brasses, gibs, straps, cotters, and bolts complete, and oil piping, guards, etc., all of which was done at the factory.

Cause of the Trouble

What had happened was as follows: The water from feed pump had backed up through open heaters till they filled up to overflow level. The overflow took care of some of the water, but the level still rose till it came to the exhaust steam opening. Entering this it dropped down to the main heating exhaust and travelled along to the building. Presumably about this time the engineering genius in the boiler room, finding he was getting no water in the boilers, speeded the pump up a bit. There was some back pressure on the engine by now but the water had not yet reached the level of the cylinder. However, shortly after it did, with the results as named. When the final smash occurred the engine was just coming to the back centre. She must have been considerably slowed down from her normal 260 R. P. M., and was probably running about half that. The L. P. piston met a solid wall of water, and the energy of the fly wheel was enough to force the rod through the piston, splitting the piston and jamming everything hard and fast. The fly wheel still possessed considerable energy, the whole of which was applied to move the crank ahead, against the resistance of the immovable L. P. piston. The weakest parts were evidently the straps in crankpin and crosshead, and these parted. The fly wheel evidently made a few revolutions after this, as the connecting rod was thrown back near the front cover, and pieces of the bearing boxes were in the crankpit and on the floor, while the oil piping gave mute testimony of what it had gone through. The shock of the sudden stop on the H. P. end of the rod had to be absorbed by the piston nut, and this had evidently been too much for it. The metal had given, and the piston had loosened in the taper and was ready to let go at the first movement. This shows what can happen through one man's carelessness, and the guilty one should be susceptible to a more drastic punishment than being discharged as in these days being discharged holds no terror for the average fireman.

MANUFACTURING STEEL BARS FOR RIFLE BARRELS

(Continued from page 506)

are made out of chilled cast iron. Their length is 12 inches, not including that of the necks and wobblers. They are two-high, each one weighing about 350 lbs., and contain the following passes: One 1 1-4, one 1 3-16, two 1 1-8, one 1 1-16, and one 1 inch pass. When the bar comes from the ovals it is taken by the workman on the finishing rolls and inserted between guides, which are used to hold it in an upright position with the sharp edge of the oval bar facing upwards.

The worker, (called the finisher) then waits until the metal is between a cherry-red and a yellow color; then pushes the bar between the guides and into the groove. The heat at which the steel is rolled in the finishing rolls is most important—too high a heat auses the oval to over-fill the round groove, thus making it mark the bar at the joints between the top and bottom rolls. With too low a heat, the metal will not fill out the groove in the rolls, it making a bar of uneven size. The setting of the guides is also a matter of importance. If one guide is set further over on one side of the groove the bar will twist from that guide and have a flat side—it will also mark the steel on the opposite side. Should one guide be set higher than the other there will be a twist from the higher guide. If the oval is not quite large enough to fill up the round groove, there will be flat sides to the finished bar. If the grooves in the top and bottom rolls be not set exactly opposite each other, the bar will be marked on the sides. It will be seen from the foregoing that the rolls have to be set very carefully in order to make perfect bars. As rust is the great enemy of steel it is customary in some mills to pass their steel bars as they come from the rolls through a trough containing cuttings of fiber or leather saturated with tar —the vapor of which gives the hot metal a thin glossy coating. The roll turners' part in designing and turning the rolls is most important and complex. Rolls that work well in some mills will not do so in others, but have to be altered. This is due to the material used and also to the engine power and steam pressure. Attempts have been made to find quicker methods of making iron and steel bars, but all have been failures. It is most likely that nothing better can be devised to displace the use of rolls for making iron and steel sections, which are used extensively in all cvilized countries.

BANKER AS GATEMAN

Wealthy Man Working at Shipyard in Seattle

James K. Corbiere, for 40 years a banker in New York City, is employed as gateman at the Ames shipyards in Seattle. Mr. Corbiere is a man of wealth. He has never had to soil his hands by hard work. He is 60 years old, exceptionally careful in his dress, and equally careful of his health and appearance. His hair is snow-white. He seldom appears without a flower in his coat lapel, and usually wears spats and carries a cane. In every respect, age, dress and habits, he is different from the accepted style of the shipyard worker. He goes to work at 7 o'clock in the morning, two hours earlier than he has been in the habit of rising; is on his feet practically all day, and quits at 4.30 in the afternoon. He has been a personal friend of Charles M. Shwab, steel king, and now director-general of the Emergency Fleet Corporation, for 30 years.

When asked how it happened that a man in his station in life, when he felt the call to patriotic duty, did not undertake Red Cross work, or offer his services in some other capacity more nearly similar to that in which he had been so long engaged, Mr. Corbiere said:

"No: there are enough men seeking that kind of work. But it appeared that there was a real need for men in the shipyards, and I believe every man should help win this war."

When asked what he was earning at the shipyards, Mr. Corbiere replied: "I do not know. I have not called for my pay."

A San Francisco chorus girl held her job for seven weeks before the director found out that she was deaf and dumb.

The Story of a Pound of Coal

Explaining the Enormous Losses Occurring When a Pound of Coal is Burned Under a Boiler, the Steam Generated Used to Run a Steam Engine, and This in Turn Caused to Drive a Dynamo Supplying Electricity For Lighting

By H. W. SECOR, Associated Editor of "Electrical Experimenter."

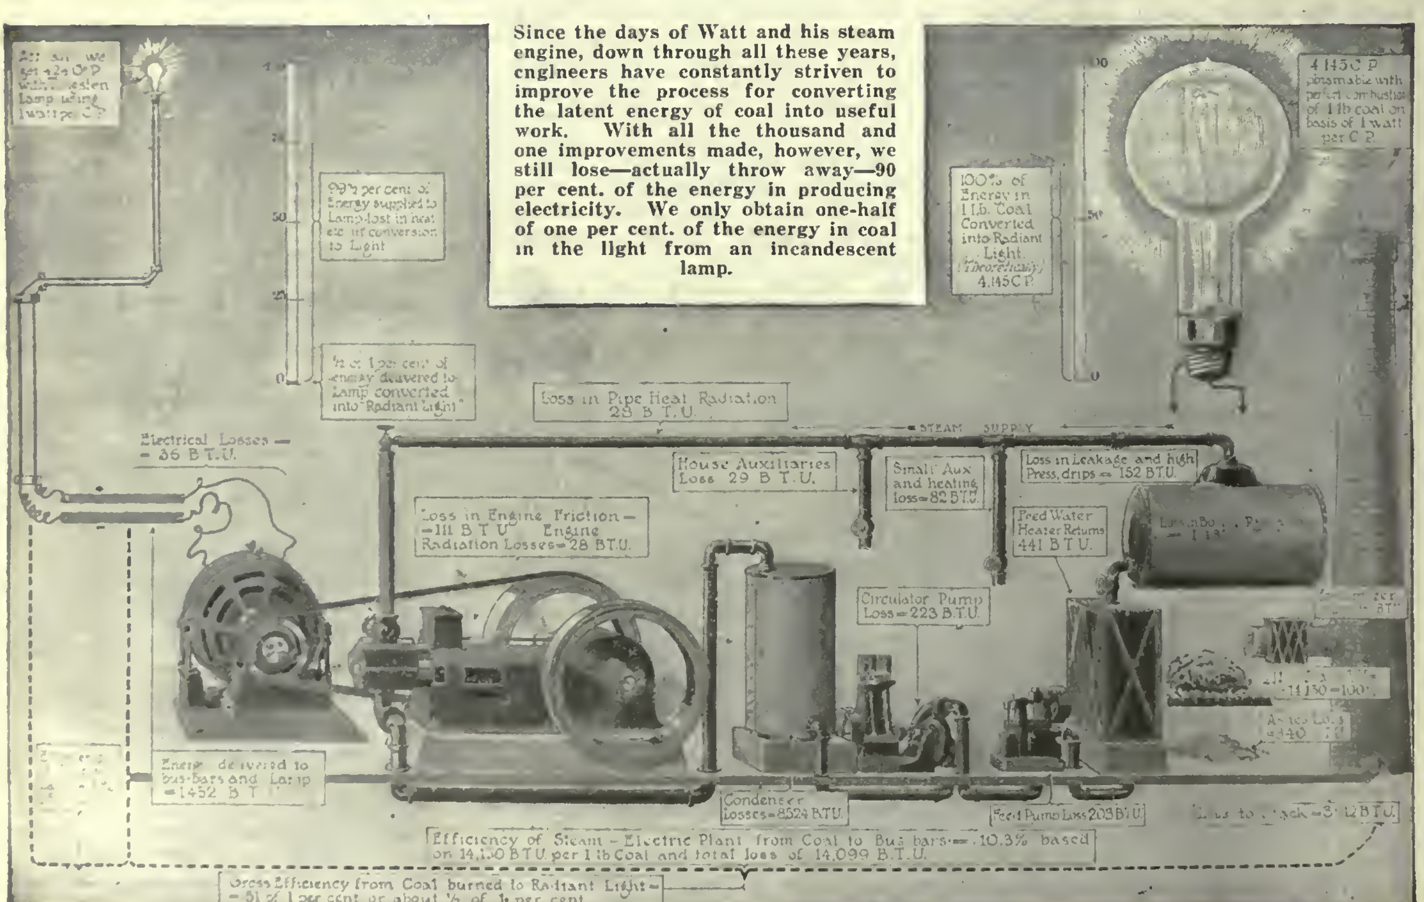
DID you ever stop to consider how much of the energy present in a pound of coal is actually converted into electrical energy, even in the best power plants of to-day? In a few words it is this—that out of every pound of coal burned in a steam boiler in an electric power station we only succeed in converting about **one-half of one per cent.** of the total energy in that pound of coal into radiant light! The average person believes that in this so-called "electrical age" we have reached well-nigh perfection, but the above figure illustrates vividly that the electrical and steam engineers have many problems yet in front of them before anything like real efficiency is attained in converting the energy in coal to **electric light**, or for that matter into **electrical energy** with which to feed the lamps and other apparatus. For the largest and most highly developed steam-electric plants of to-day do not realize an over-all efficiency of much above **ten per cent.**

This figure of ten per cent. represents the ratio between the coal burned in the boilers and the current delivered by the dynamos to the bus-bars, and shows that what most persons believe to be a wonderful and highly efficient electric power generating station is really throwing away about 90 per cent. of the energy in the coal it buys.] A modern water-power electric generating station may show a gross efficiency of as high as 56 per cent.; therefore there is something radically wrong with our coal-burning methods, beyond the shadow of a doubt. Several well-known inventors have ventured to design a different type of apparatus for developing electrical energy direct from coal, but so far no commercially successful method has been perfected. Even Edison has tried his hand at perfecting such a machine, but so far we have not advanced beyond the well-known boiler and fire-box stage in our commercial utilization of the energy in coal.

Therefore it is of interest to study this important subject a little and to find out where this enormous loss takes place. The accompanying illustrations show in a graphic manner just where these losses occur in each part of the system of a modern steam-electric plant. The various losses and efficiencies are taken from a report made in the transactions of the **American Institute of Electrical Engineers** by a well-known electrical engineer, Mr. H. G. Stott, and represent the efficiency of a large steam-electric plant. Some of the large present-day plants of this type obtain a slightly higher over-all efficiency than the one here cited, for instance, the Interboro Rapid Transit Company's plant in New York City showing a gross efficiency between coal burned and electricity developed, of about 12 per cent.

Let us now resume the discussion of the present steam-electric plant here illustrated. In looking at the illustration from right to left, keep in mind the energy in a pound of coal at the start, viz., 14,150 B. T. U. (British thermal units.) One B. T. U. is the amount of heat required to raise the temperature

(Continued on page 526)



Since the days of Watt and his steam engine, down through all these years, engineers have constantly striven to improve the process for converting the latent energy of coal into useful work. With all the thousand and one improvements made, however, we still lose—actually throw away—90 per cent. of the energy in producing electricity. We only obtain one-half of one per cent. of the energy in coal in the light from an incandescent lamp.

DEVELOPMENTS IN SHOP EQUIPMENT

Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.

THE CLEVELAND MILLING MACHINE

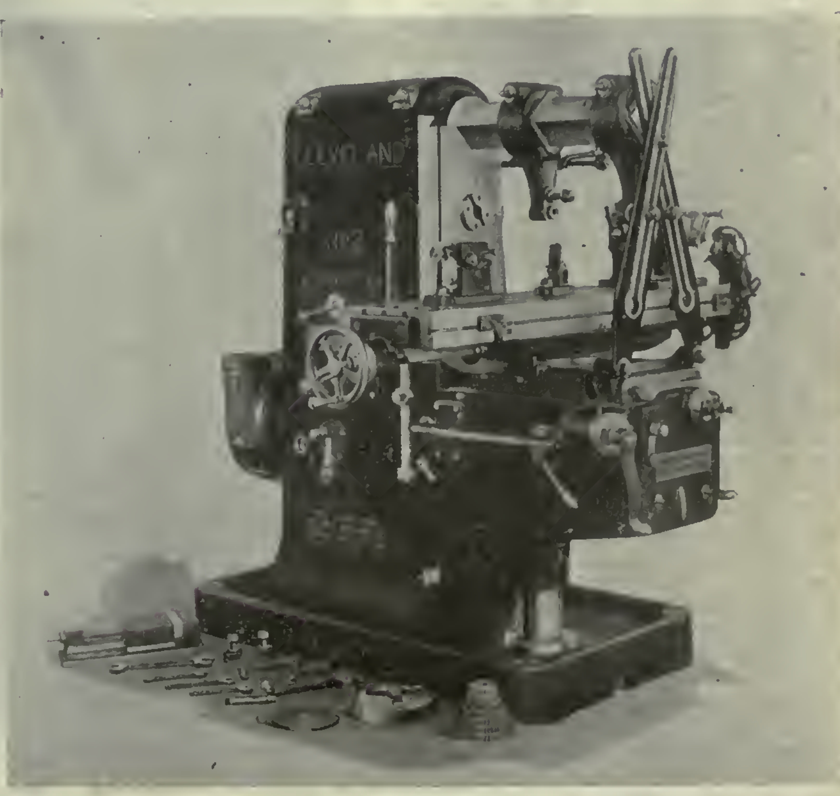
THE accompanying illustration shows the Cleveland milling machine developed by the Cleveland Milling Machine Co., Cleveland, Ohio. In the design of this machine, structural features have received great attention, and the operating characteristics lend themselves to ease in operation and quantity production.

The Cleveland milling machine is a constant speed driven type with sixteen changes of spindle, and sixteen changes of feed. Speeds and feeds are controlled by two levers of the ball-joint type, similar to an automobile gear shift. All changes for both speeds and feeds obtained through sliding gears only. Both are automatically lubricated.

The column is of very rigid construction, being a complete box section. The base and the column are in one piece, a heavy ribbed semi-steel casting being used, tied together with heavy vertical and horizontal walls. The only openings in the column are those necessary for the change gear levers on the front, the pulley drive housing in the rear and the cutter lubricant tank on the left side of the machine. It never becomes necessary to open up the column, as all the parts inside are automatically lubricated, and all adjustments on the bearings are made from the outside. The dovetail knee slide extends upwards to the overarm. This offers ample surface for clamping attachments. The depth of the column has been carefully determined in order to place the spindle and the shaft bearings at the correct distances apart to secure the maximum rigidity. On account of the design of the horizontal and the vertical walls to separate the lubricating oil for the machine from the cooling compound used for the cutter, the column is very rigid. The base of the machine is ample in size. Transverse and longitudinal ribs tend towards rigidity. It is also finished on the under side so it will stand solidly on its foundation. The base is pan-shaped and has enough depth to catch oil and chips, thus keeping the surroundings clean.

Next in importance to the column is the knee. It is therefore necessary that the knee be especially designed to withstand all the weight that is put upon it in doing heavy work. The knee as well as the column has an improved dovetail slide. The bearing of the saddle is not on the thinnest section of the dovetail slide, but on the flat wide surface. The narrow slide acts as a guide only. There is no bearing on the center of the dovetail slide. This eliminates chances of having same marred by the operator laying wrenches or tools on the top of the knee. The bearing of the knee on the column is carried well above the top of the saddle slide, thus giving the knee a longer bearing on the column and reducing the bearing pressure to a minimum. The feed box as well as the knee is entirely closed, eliminating any possibility of chips getting into the feed mechanism. The elevating screw is large in diameter, and in one piece. The post acts as both support to the elevating nut as well as a guide in the knee. The screw is operated with a double bevel gear, hand feed and power feed being independent of each other.

With the table and saddle of all milling machines comes a most trying problem for designers of machine tools, as these are subject to torsional as well as bending movements. The table is machined all over, to keep its alignment, as it has been proven that a table finished only on one side is liable to warp, on account of the internal strains. The bearings on the table are at the top of the saddle instead of at the bottom of the dovetail. This method secures a large bearing surface and locates the bearings at greater distances apart. These bearings are automatically lubricated by rollers in the saddle. The bearing on the saddle is also at its widest portion, and both saddle and table bearings are taken up with long taper gibs which are provided with adjusting screws at both ends to make up the wear.



CLEVELAND UNIVERSAL MILLING MACHINE

The square overarm provides positive alignment of its arbors and maximum rigidity of the arm pendants. If the arbor is not exactly true and the arm pendant is brought into place by the operator to accomodate the arbor, the arbor under these conditions is working in a cramped condition and will shortly be crystallized and break. With the square overarm it is impossible for the operator to place the arbor supports on the overarm and on the arbor in any other way than exactly in line. The square overarm also enables work to be placed on the table and be fed in a vertical position past the overarm. Owing to the firmness which the square overarm imparts, a greater variety of work can be performed than would be otherwise possible.

A flanged spindle eliminates the overhang end of the spindle as well as the trouble caused by cutters screwing fast on the spindle and also allows the cutter to be run in either direction. On the flanged spindle is a face keyway, inserted into which are hardened steel jaws for driving the arbor as well as the face mills. It is unnecessary to remove these at any time to change from the face mill to an arbor, as the driving is done by the hard steel jaws. The strain is therefore taken off the taper hole to drive the arbors. The spindle is provided with a positive lock that enables the operator to loosen the arbor nuts with the least possible difficulty. The spindle lock cannot be operated while the machine is running, nor can the main driving clutch be thrown in while the spindle lock is in this position. The bearing on both the front and rear end of the spindle is taken up with a nut on the outside, at the back end of the spindle.

All bearings in the column and knee are flooded with lubricant, thereby taking the responsibility for oiling the important parts of the machine off the operator entirely, and eliminating the necessity for having oil holes in any of these members. This system is highly efficient and is entirely automatic. The reservoir containing the oil has to be filled but twice during the year. Embodied in the design is a centrifugal pump which operates only when the spindle does, therefore it is necessary to shut off the cutter lubricant when changing work or measuring same. This operates automatically when the clutch is thrown in starting the machine.

The speed and feed arrangement are both of the sliding gear type. All sixteen changes of spindle as well as feeds are made by two levers conveniently located to the operator. The spindle speeds are sixteen in number, in either direction, and the feeds are sixteen in number also, so that this machine will efficiently handle all classes of cutters, speeds and feeds, and being in geometrical ratio, gives the correct changes of feed for the work to be done. All gears and shafts in the drive as well as the feed are hardened steel, automatically lubricated, running in bronze bearings.

Power is transmitted through a constant speed drive pulley and is so designed that it requires no loose gears on the spindle. All shifting of gears is done on the secondary shafts below the spindle. The starting or stopping lever can be operated from both sides of the machine. The single pulley running at constant speed for the drive is protected by a belt guard and is so constructed that it can be adjusted to any angle and extensions can be added to it. The spindle reverse is contained within the machine so that right or left hand cutters can be used on the machhine. All the speeds, feeds, and other driving mechanism is self-contained within the machine, it not being necesary to have any driving mechanism bolted on the outside of the column of the knee.

METAL SAWING MACHINE

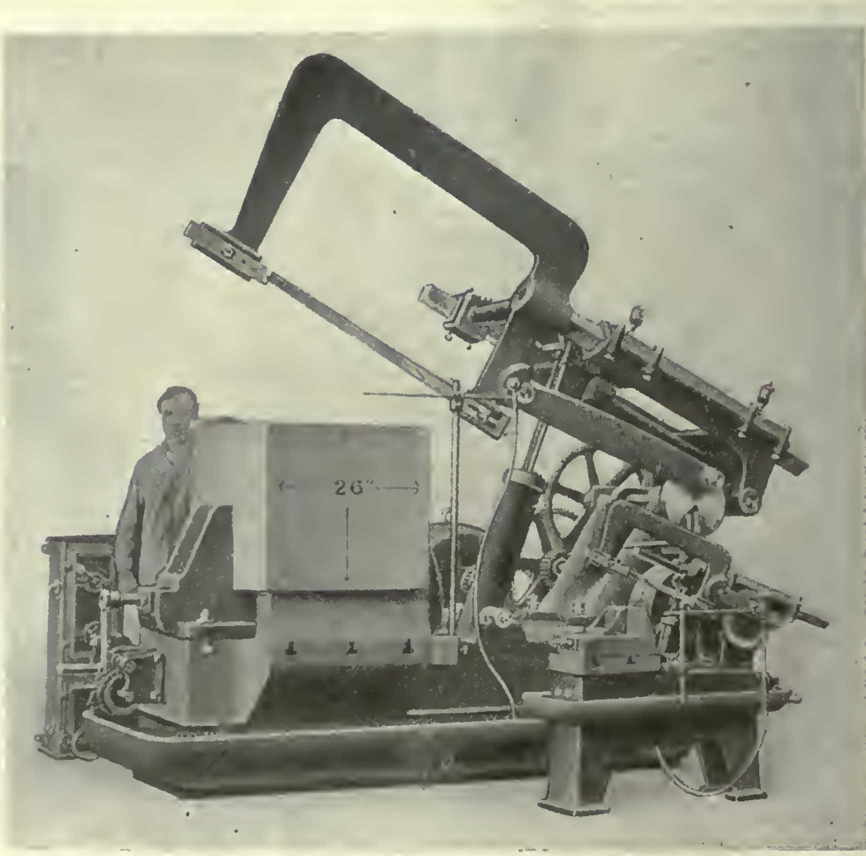
The hack sawing machine illustrated by the enclosed engraving is one of the largest machines of this type that have been made. It weighs 3½ tons and will saw through a billet of oil hardened gun steel 26 inches square. The machine was specially designed and made for one of the Royal Naval gun factories in the north of England by Messrs. Edward G. Herbert, Ltd., Atlas Works, Levenshulme, Manchester.

This firm was one of the first to appreciate the possibilities latent in the old Millers Falls hack saw and, by the production of heavier quick cutting machines, elevated the hack saw to the position of a real production machine tool, competing with, and frequently replacing circular and band sawing machines.

The general design of the machine is similar to that of the "Rapid" sawing machines made by this firm. The saw frame is 3 feet deep and 5 feet wide over all and takes blades from 24 inches to 39 inches in length and 2 inches wide. The main slide bearing is 3 feet 6 inches long and the main driving shaft 3 inches diameter. The slide is pivoted on a separate shaft. The heavy frame is counter-balanced by springs in the bed of the machine and the pressure of the saw blade on the work is regulated by a worm wheel and indicated by a dial. The saw blade cuts on the outward stroke and is lifted from the work on the return stroke. Although the weight of the frame is considerable the blade is lowered on to the work at the commencement of the stroke without any shock.

The saw frame can be raised and lowered by hand through worm gearing at the front of the machine. The worm is dropped out of gear when cutting begins and the feed is by gravity. In the same factory there are five No. 3 motor driven "Rapid" sawing machines, sawing up to 15 inches diameter, these being the largest machines previously made by Messrs. Edward G. Herbert, Ltd. They are engaged in sawing test pieces from oil hardened gun tubes and jackets.

All six machines are looked after by one unskilled man and a woman. One saw blade will cut through the 26-inch square billet and still remain serviceable. The motor fitted is a 3 H. P. 2/1 variable speed motor made by the Lancashire Dynamo & Motor Co., Ltd.



Procedure Regarding Export Licenses

Effort Being Made Now to Simplify the Rather Intricate System That Had Come to be Used in War Order Business—Lists of the Lines That Are Affected by the Order

WASHINGTON.—1.—The War Industries Board and the War Trade Board announce that they have jointly adopted the following rules and regulations for the purpose of simplifying the procedure of obtaining export licenses from the War Trade Board, priority certificates from the Priorities Committee of the War Industries Board, and permits from the director of steel supply of the War Industries Board.

2.—The War Industries Board announce the withdrawal of its regulations as set forth in P. C. Form No. 18, July 3, 1918, paragraph 6, requesting that applications for licenses to export iron or iron and steel products should not be filed with the War Trade Board unless the orders are covered by either priority certificates or permits from the director of steel supply.

3.—On and after October 14, 1918, applications for licenses to export any article on Schedule "XP," annexed hereto, should be filed with the War Trade Board, and must include the following papers properly executed:

(a) One application, Form X, to which should be attached:

(b) One each of such supplemental information sheets as may be required by the rules and regulations of the War Trade Board to be used in connection with shipments of certain commodities and shipments to certain countries, and

(c) New supplemental information sheet, Form X-26, which will be ready for distribution by the War Trade Board on and after October 14, 1918.

4.—Applications which have Form X-26 attached will not require Form X-2.

5.—The Priorities Committee of the War Industries Board has awarded priority classification "C" to all articles (on which priorities are issued) which are on the export conservation list of the War Trade Board and are covered by export licenses issued on and after October 16, 1918. No class "C" certificates will be issued with such licenses. If the article specified on the licenses is one on which priorities are issued, and if no individual priority certificate accompanies the export license, the license itself will be evidence that the articles covered by it have been automatically awarded priority classification "C."

6.—Export licenses issued on and after October 16, 1918, under these regulations. covering commodities on which priority certificates are issued, will be accompanied by individual priority certificates of the Priorities Committee when in the opinion of the Priorities Committee a higher rating than Class "C" is of the Priorities Committee a higher rating than class "C" is warranted. These priority certificates will be issued by the Priorities Committee and forwarded with the export license without further request from the applicant.

7.—Export licenses issued on and after October 16, 1918, for the exportation of iron or steel or the products or manufactures thereof, which are not covered by priority classification, will in themselves constitute a permit and approval from the director of steel supply for the filling of the orders for the quantity of iron or steel specified in such export license to the extent that such delivery will not interfere with the delivery when and as required of orders covered by priority.

8.—It is the policy of the War Industries Board and the War Trade Board to discourage and prevent exporters and manufacturers from purchasing, manufacturing, or producing articles on the export conservation list for the fulfillment of specific export orders until an appropriate export license has been issued. Instances have come to the attention of the War Trade Board in which manufacturers before obtaining export licenses have manufactured articles foi specific export orders, which articles, while useless for domestic consumption, could not under the regulations of the War Trade Board be exported. It is essential for the proper conservation of commodities in the United States that this practice be stopped, and it is the purpose of the War Trade Board to refuse licenses to exporters who do not conform to this policy.

9.—The Priorities Committee announces that it undertakes where necessary to administer priority in the production of all raw materials and finished products save foods, feeds, and fuel. The preference list promulgated by the Priorities Board forms the basis for the distribution of fuel. Priority is being administered generally on iron and steel products, copper and brass products, electrical equipment, and the products of which any of the above form an integral part. Priority is not being administered at this time on lumber or lumber products, paper or paper products, chemicals, brick, cement, lime, hides, pig tin, tin plate mine products, and numerous other items which cannot well be enumerated. It is not possible to prepare lists in detail covering either prioritied or nonprioritied products, and even in those mentioned above exceptions will from time to time occur. Any inquiries with respect to the commodities upon which priority is being administered should be addressed to the priorities committee of the War Industries Board.

VANCE C. McCORMICK,
Chairman.

Schedule XP, Referred to Above

Pig iron.

Ferro-silicon.

Spiegeleisen (frequently described as specular iron and mirror iron).

Iron and steel: Scrap, ingots, billets, blooms, slabs, sheet bars, skelp, wire rods, alloy steel, high-speed steel, tool steel, bars (including flats 6 in. wide and narrower); hoops and bands (including hot and cold rolled strip steel); shapes (including beams, angles, channels, tees and zees); fabricated structural steel (including beams, angles, channels, tees, zees, or plates ⅛ in. thick or heavier, punched or shaped, including tanks made of plate ⅛ in. thick or heavier). Plates (all classes ⅛ in. thick and heavier and wider than 6 inches, and circles over 6 inches in diameter. This includes No. 11 U. S. gauge but not No. 11 B. W. gauge). Sheets (all classes under ⅛ in. thick). Boiler tubes, mechanical tubes, boring tubes, oil well casing, line pipe, drive pipe, cast iron pipe, wrought iron and steel pipe, poles, wire rope, cable and strand, consisting of 6 wires or more, rails and splice bars, frogs and switches, railroad tie plates, railroad track spikes, railroad track bolts, boat spikes, wire, wire nails, wire spikes, cut nails.

Never Meant for Scrapping

A scrap iron dealer in Harrodsburg, Ky., recently bought from an old colored "Auntie" an old-fashioned iron stove which evidently had been made in the early days of stove manufacturing. A big door in it could be raised to let in andirons on which wood for the fire could be placed.

When men in the dealer's yard started to break up the stove they found that the iron was nearly an inch thick, and they tried in vain to wreck it with heavy sledgehammers. Finally the stove was sold intact as an antique.

Steel Workers in Service

The United States Steel Corporation's service flag now shows 25,985 men from its plants are in the army and navy. The corporation has word so far that 60 of its former employes have been killed at the front.

Companies Incorporated. Incorporation has been granted to the following: Mabee Condensed Milk Company, Ltd., Toronto, capital $1,500,000; The P. Q. Towing Company, Ltd., Dalhousie, N. B., capital $50,000; Petrie Manufacturing Company, Ltd., Hamilton, capital $2,000,000; Consolidated Machine and Tool Company, Ltd., Brantford, $500,000.

Vol. XX. OCTOBER 31 No. 18

Clipping Coupons Is Profitable.

THE army of coupon clippers in Canada is growing. Not long ago the term "bond" used to scare people. It wasn't something that the average individual had anything to do with. It had an atmosphere of private offices, ease and luxury that belonged only to those who had made their wad.

But of recent years there have been a heap of people in Canada who have found out from actual experience that a bond is a mighty fine little thing to have around the premises, and also that coupon clipping isn't a very painful operation after all.

The public has come to realize that lending money to the Government at a little over five per cent. is away ahead of buying oil stocks, mining securities, or taking a chance at industrials that may go or go under.

And it's that feeling that is going a long way toward making the Victory Loan a success. The Loan is attractive apart from any patriotic appeal that can be made on behalf of it. It is tax-free. It ought not to be, but it is. The Government should never have started this form of tax dodging, but having started it, it now fears to jeopardize the success of the issue by making it liable to taxation. The purchaser of Victory Bonds gets the benefit of the early course, mistaken though it was.

The Canadian mechanic need not hestitate about putting his money into the war loan. He can afford to strain a point in paying for his bond. Take it as a hard business proposition, apart from the patriotic considerations, apart from what it means to Canadian business—the Victory Loan is an investment chance that does not come often. The man who has not invested before should get his schooling in this good thing.

German Money a Real Boomerang.

THERE'S one man in United States who has broken all records for buying bonds. The way he tosses out millions for the Liberty Loan would make Carnegie or Rockefeller gasp and reach for the railing to keep from being swept off the deck.

His name is A. Mitchell Palmer. Already he has bought $60 000.000 worth, and he's still going strong. If you want to know how it's done, here's the explanation in Mr. Mitchell's own words:—

"Possibly I have some little right to be a Liberty bond salesman, if there is any merit in the maxim "practice what you preach," because they tell me I am the biggest buyer of Liberty bonds in America. I have got something like $60,000,000 worth, and it is a poor day when I don't subscribe for $1,000,000 more. For me it is an as well as a pleasant task because I buy Liberty bonds with the Kaiser's own money."

It so happens that Mitchell is Alien Property Custodian of United States. Here's how he operates.

"Why some few weeks ago, out in a western city, a school-teacher who was a German-born woman. died, and in her will she bequeathed $10,000 to von Hindenburg. I got that. I invested it in Liberty bonds and the proceeds were used to buy ammunition, and now Pershing's boys are trying to deliver the legacy to von Hindenburg over in Germany.

"We have made every dollar of German money in America fight the Germans. Great iron and steel mills, which were wont to send their profits out of America back to Germany, are now sending their profits to the Treasury of the United States and their product into war munitions to destroy their owners.

"Great woolen mills over in New Jersey, which were wont to send large dividends back to Berlin, are now sending those dividends to Washington, and working every loom and spindle to make those Army suits for the boys with Pershing in France.

"Great metal, mining, and mineral companies all over the United States, owned with German money, are working night and day, three shifts to the day, to produce material, not for the German over here to plant his industry in our midst as a sort of spy system against us, but for the United States, which he sought to destroy."

It is well to realize that war is not play. It's plain hell, and a nation must handle it in that way. Love taps don't fizz on the German either on the western front or in this country. Politicians are gradually coming to the stage where they know the German hasn't got a vote just now, and they're licked if they stop to reckon about the votes he may have in years to come.

Well, Here's Your Chance Now

WHEN pay is good and work is thick and things are runnin' smooth, when there ain't no bumps nor kinks to hurt the slidin' in the groove—when all them things is happenin', boy, when you're a man of means, why don't forget to now and then put a ten into your jeans.

It's easy for to take your cash and fling it far and wide, to put fresh fixin's in the house, new duds upon your hide.

There ain't no end to things to buy, vou've found that bloomin' store. You'd like to cut a swath, me boy, that's out before, these things they beckon on to you in every sixteen yards across, and doll yourself to be the likes of some ten thousand boss. .

But just remember all the same that fat pays come and go, that after summer comes the fall and trailin' that the snow.

It's nice to spend, we all know that, it aint no trick at all, to flash your dust at every curve and toss to every call. It sometimes takes a little nerve to stay upon the sod and quietly sprout another ten unto your little wad.

But here's the time, me boy, to take and blow your bloomin' pile, and stick your chest six inches out and hatch a wholesome smile. Yes, here's your chance to stake your cash in somethin' good as gold, that wouldn't grow stale upon your hands nor yet grow stale with mold. And here's your chance to help the boys what's gone across the pond—by buying deep and long and loud that good old Vict'ry Bond!—ARK.

AFTER all said and done it's a great thing to mind your own business.

* * *

PUTTING the hell into shell is really the work of the munition plants at present.

HARD WORK AND HARD STUDY DID IT

Arthur A. Hopkirk Wanted to Drive a Locomotive When He First Entered Shops.

SIX years ago an unassuming young man earned one hundred and twenty-five dollars a month. To-day his monthly salary is four hundred dollars plus. On pay days he signs five hundred and seventy-five cheques. Above his signature is the firm name Universal Tool Steel Company. Below his signature is his official title, superintendent. Arthur A. Hopkirk is his name in full, but his signature is simply A. Hopkirk. Better reasons for our saying he is unassuming could be told.

ARTHUR A. HOPKIRK

One is that he confessed to having been a messenger boy the first year or two after leaving public school. Out of his earnings as a messenger he saved enough to pay his own way through one of the business schools.

Figuratively speaking, it was only a step from the school to an insurance office. Typewriters rattled and bond papers crackled and routine wove its web. Something in Hopkirk rebelled.

The general master mechanic of the C.P.R., West Toronto shops, lived across the streets from his home. One day he asked the father of young Hopkirk what he was going to do with his boy.

"You'll have to be more definite," the father of seven boys smiled.

But the boy meant was ripe for any change that would take him away from stiff-collar monotony.

Variety thrived in the general master mechanic's office. So did young Hopkirk. There were men in and out that knew a joke. There were yard engines and spare moments to be spent in their cabs.

Perhaps those rough and ready, but verily salt of the earth, railroaders, were good guessers or perhaps they were not. However, that may be, they knew nothing of the sizable ambition squelched by their answers to the questions Hopkirk put with seeming unconcern. At the end of a year he knew the worst. He could never be the proud driver of a locomotive. His eyes were not long-sighted enough.

He had not shared his ambition with a soul. Neither would he share his keen disappointment. He was a shy, studious lad with inner thoughts that he could not bring himself to tell.

After a year and four months in the general master mechanic's office he went into the shop proper, and for five years he served as an apprentice.

In the fourth year of his apprenticeship, when making seventeen cents an hour, he married the world's most courageous girl. At least so he thinks of her now when thoughts go back to their two-roomed home.

The next year he finished his apprenticeship and went with the Canada Foundry where he commanded journeyman's wages right away. But six months later the C.P.R. West Toronto shops offered as good pay, and he returned.

"I worked three more years in those shops, studying in my spare time," he told me. "I took a correspondence complete course in mechanical engineering. About this time, too, your technical papers had a good deal to say about shop efficiency. As well as reading all I could find on the subject I made time studies in relation to production myself.

"I guess some of the men thought I was a nut, but I knew what I was doing and tried to be indifferent to their talk while continuing my studies.

"Just before the three years were up I wrote S. J. Hungerford, general manager of the C.N.R. I told him what experience I had had, the progress made in my studies, and that I thought possibly a young man would stand a better chance for quick promotion in one of the western shops of the C.N.R.

"It wasn't long after that A. Dickson, then our general foreman, came to me with a letter from A. E. Eager, shop superintendent of the C. N.R. at Winnipeg. Eager wanted to know if I had any right to be so ambitious, and Dickson evidently told him that I had.

"So I went to Winnipeg as C.N.R. shop engineer. I went on trial for three months at one hundred and twenty-five dollars a month, but I stayed three years.

"And it is now three years since I returned to Toronto. Galloway preceded me by no more than a week or two. He came East to accept the superintendency of this plant. I came to act as general foreman.

"We started on eighteen-pounder shells. Our second contract was for eight-inch. Then we switched back to the former, and since the first of the present year we've been making six-inch howitzer. Each change entailed a rearrangement of the plant, and that was no cinch," the speaker said emphatically.

Six months ago Galloway was made general manager of the J. J. Carrick plant at Buffalo. Arthur A. Hopkirk, thirty-seven years old, was given his private office and all that goes with it. He speaks modestly of his success, but if you are a young man and sincere, he will tell you that hard work and hard study put him where he is to-day.

SIR THOMAS WHITE,

Finance Minister, of Canada, who has given lucid explanation of the Victory Loan.

MARKET DEVELOPMENTS

New Regulations Are Causing Some Concern

French Experts Have Very High Opinion of Efficiency of Canadian Shell Shops—All Steel Materials Will Likely Come Under Government Observation and Control

THE warehousing business in Canada is surely coming to the point where it works in rather uncertain channels. For a long time material of less than ⅛-inch in thickness was not included in the embargoed list, and firms that had a good connection at U.S. rolling mills had little trouble in "carrying on." Even when the War Trade Board turned down an application for the release of certain material—particularly plate—they often did so with the recommendation to "use some lighter material." This provided an easy way out, but now this lighter material is under the same ban.

Canadian shops maintain a very high standard of efficiency on shell work. A party of French mechanical experts are in Canada at present, under the guidance of an interpreter from the Dominion government. They have been in United States for some months in connection with French orders. They state positively that in point of production and the well-planned arrangement of the sequence of operations, Canadian shell shops are absolutely the best in the business.

Inquiries for equipment in machine tool circles are mostly for 155 m.m. contractors. Those shops that are producing now are in much better position to add, piece by piece, to increase their output, than new plants are to go out for an entire outfit. Dealers have odd machines on standing orders, and delivery in this way is comparatively rapid.

Supplies were sent forward this week for the mechanical equipment that is to accompany the Canadian expeditionary force to Siberia. Apparently nothing is being lost sight of that will be needed to make the force self-sustaining as far as repairs are concerned. Shipment was made to the embarking point at Vancouver.

United States War Industries Board has given notice that the manufacture of lawn mowers will have to be curtailed for the present.

Scrap metal dealers are having an off month. All those who have any stock on hand are apparently looking for purchasers, but purchasers are few. As a matter of fact, a large amount of this business passes directly from seller to melters, to the exclusion of the dealers.

NO PANIC EXPECTED WHEN PERIOD OF RECONSTRUCTION DOES ARRIVE

Special to CANADIAN MACHINERY

MONTREAL, Que., Oct. 31.—Few industrial activities have been directly affected by possibilty of an early termination of European hostilities. Some signs of this though are apparently not pronounced, but the impression may be gathered from the remarks of those who are in a position to know and that period of readjustment may come at almost any time. However, it is the opinion of many that any likelihood of a panic will be avoided by the operations of the War Trade Boards, as it is believed that these bodies will continue to regulate and control the situation for some time after peace is declared. The demand for machine tools is a little quieter and dealers report this due to the peace movement now on foot. Plants working on American orders, however, are losing no time completing their equipment, as it is intimated that the temporary lull will be shortly followed by increased activity. Operations on the new plant of the Canada Cement Co. have been temporarily suspended, owing to the fact that some change may be made in the size of shell to be manufactured. Industrial work in this district is still affected by the influenza scourge and output has been interfered with; during the past three weeks the Canadian Vickers plant has had over 500 men affected.

Less Demand For Futures

The dominating feature of present activity is the apparent nervousness that prevails in many circles. Frequently this feeling is partly hidden in the announcement that the war will last for a long time yet, but the atmosphere is so full of uncertainty that early future predictions are virtually impossible. The general steel situation shows little change over the past few weeks, but more reluctance is evident in the placing of orders for future requirements, and many of those placed are done so subject to such conditions as may exist at time of delivery. An influencing factor on present transactions is the fact that U. S. Government requirements are being placed with the mills subject to cancellation, providing the same will not materially affect the operation of the plant. Early future conditions hinge on the outcome of the present movement for an armistice. Should current negotiation end in a cessation of active warfare it is more than possible that certain industries will be curtailed to meet the changed conditions. The first to be affected will doubtless be that of steel and in particular that branch related to munitions. However, it is not anticipated that any sudden collapse will follow, as it is thought that the intention of the Government War Boards is to maintain a state of equilibrium while a gradual return to normal is attained. This action is not only advisable, but essential, in view of the vast increase in production facilities during the past three years. Under no form of control the market would rapidly assume a panicky condition, which would be detrimental to future prosperity. The demands for material for present and immediate future needs are still insistent, but a notable decline is reported in the orders that are being placed now for 1919 delivery. This attitude will likely continue until some definite announcement as to Germany's intentions is known. Little consideration is yet given to ordinary steel requirements, as essential operations are still sufficient to absorb all the available material. The local situation remains unchanged and the attitude of the dealers here is one of watchful waiting. Present quotations are only a guide to existing conditions, as purchasers are advised that in the majority of cases the prices are only of a nominal character.

Metals Are Easier

General conditions are having the effect of making the metal market easier and price quotations are declining. Present peace possibilities and the unsettled condition of the trade is the influencing factor, and as a consequence, buyers are acting cautiously in covering their future requirements. Should the war terminate in the near future it is thought that quotations on some of the metals would show a marked falling off, notably spelter and lead, and probably tin. Copper will be less affected owing to the strict regulations now governing the sale and distribution of the metal. Dealers here are now asking 31 cents for lake and electro and 30½ cents for castings. Tin, which was quoted at about 95 cents last week, is now 90 cents. Spelter shows a slight decline, the current quotation being 10½ cents per lb. Antimony at 15 cents is a decline of one cent per lb. Aluminum quotations are about 46 cents per lb.

Tool Trade Affected By Peace Talk

It is quite natural to assume that uncertainty will upset the operations of any enterprise and this appears to be true in respect to machine tool activity. During the past two weeks there has been a noticeable decline in the placing of orders for future delivery, as many buyers are reluctant to purchase under present unsettled conditions. This peace talk, however, has had little effect on manufacturing, as tools now on order are still urgently needed, and it is not anticipated that any letting up will take place until something definite has been decided on. One dealer here goes so far as to intimate that in another month everything will be going full swing again, on the supposition that present negotiations will not end in a satisfactory settlement. Nevertheless, the tendency in all directions is to retrench in the matter of covering future needs. Dealers in small supplies and tool steels report a slight falling off in the demand, particularly for large lots.

Little Market In Old Material

Recent developments in the war situation have added to the general dullness that has characterized this market for the past several weeks. What little transactions have been maintained are more or less of a local nature, to cover the requirements of small consumers. Heavy trading has been virtually eliminated and under the present unsettled state dealers are not anxious to stock up their yards with a lot of material. With munitions operations entirely controlled by the War Trade Boards the business of the small dealers is confined to a relatively small area. Current quotations are unchanged, but are more nominal than actual.

POINTS IN WEEK'S MARKETING NOTES

Pittsburg reports that steel mills and blast furnaces are being seriously interfered with by the spread of Spanish influenza.

—

Scrap metal dealers state that there are many more sellers than buyers in the market at present, and from this they look for lower prices in the near future.

—

A party of French experts visited Canadian shell shops this week. They stated that the shops of the Dominion were the best they had seen from the standpoint of production and efficiency.

—

Large orders of machine tool supplies were shipped this week for the use of the Canadian Siberian expeditionary force. They were sent to Vancouver, where all the material is being assembled.

—

U. S. War Department sent telegrams to operatives not down with influenza to redouble their efforts to keep up the production of machine tools for the fitting out of the war plants.

—

Makers of lawn mowers can operate on a forty per cent. basis up to January 1 next, after which time they are expected to go on war work on a 100 per cent. basis.

—

Some war contracts were cancelled in the United States by the government, but this does not indicate any let-up in their plans. The cancellations were made simply because the deliveries could not be made on schedule time, or anything approaching it.

HARDER THAN EVER TO SECURE MATERIAL

Jobbers Not Certain How The New Regulations Are Going To Work Out

TORONTO.—Victory Loan has right of way this week. It's talked of more than the war, more than production, more than machine tools and more than all of them put together. It's surely the cock of the walk for the time being, and any little attention that such common things as trade affairs happen to secure is simply as a word thrown in edgeways.

Machine tool dealers are doing a satisfactory business. There is still talk of 155-m.m. plants, although were they started now it would mean, that with the very best luck and management, they could not produce shells before March or April of next year.

The tendency seems to be to bring the plants already operating to a greater degree of efficiency rather than to start new ones on the road. It is not such a difficult matter to do this, as dealers can supply odd machines for very quick delivery, where the extensive equipment that goes into a new shop takes many months to secure and bring to the point of operation.

For the present the 155-m.m. work seems to hold the greatest interest, and the chances seem to be that this will continue to be the greatest centre of production in Canada for some time yet.

In Smaller Compass

It can be correctly stated that the steel trade looks now for more action in regard to the output of steel, not only in the shape of plates and sheets, but in everything else that has steel in it. Jobbers are not quite certain how they are going to come out in the scramble, but they are quite certain of one thing, and that is that there is apparently no let up in the way that orders are being turned down by the War Trade Board at Ottawa. Formerly it was possible to get material in under ⅛ of an inch in thickness, as this was not on the embargo list. It has been the custom of the trade, and of the government as well to advise users who have been calling for No. 10 gauge to substitute comething lighter, In many cases this has been done. But now the "something lighter" is included in the list of things that have to be passed under the embargo, and the trade is wondering just where they are going to come in under the new order of things. The opinion is also expressed that much of the later movement is due to a desire to straighten out the rather intricate system that has been worked out, by the use of licenses and priorities as well. Just this week war business of a very positive nature was turned down for a firm that is forging for the American government, and the material—plates in this instance—was urgently needed. The usual advice of using something lighter was given, but the trouble is going to be the securing of the something lighter. The jobber who secured the order was so sure that it would be passed at Ottawa that he would, had there been the urgency in the case, have shipped the material along, taking a chance on the War Board sanctioning the release of the material from the warehouse. As a matter of fact applications are getting turned down right and left at Ottawa at present.

A Dull Scrap Market

"We can't say that we are in for an era of lower prices, but there are many things pointing that way," stated one of the large dealers this morning. "The trouble is just now," he continued, "that every person wants to sell their stock, and very few people want to buy in quantities that will make a dent in the large reserves that are being stacked up in almost every place. The result of such a situation is almost invariably that the prices will be forced down, although we cannot say it has come to that yet. Quotations have not come down, but the chances are that they will before long."

There are quite a number of deals put through in which the dealers have no share, and the material passes directly from the sellers to the melters.

The Machine Tool Trade

The month just closed has been a good one for the machine tool trade and for the supply departments as well. The 155-m.m. work accounts for the most of the demand. There is quite a bit of replacement and addition business coming in, and this can be handled to much greater advantage than the putting in of new plants. Dealers have stocks from which they can draw for odd pieces and give good delivery.

Dealers in supplies, especially of high speed goods, report that there is a tendency to buy pretty close to actual needs. The peace talk that was rampant some weeks ago made the producers of shells a little anxious lest some of the cancellation provisions should come into operation. As a result the shops are not very well stocked with this class of material, and when orders do come in they are wanted at once.

Equipment for the Siberian expedition has been furnished by a number of Toronto dealers. A large consignment of reamers, cutters, taps and drills went to the shipping point, Vancouver, this week.

Dealers report that deliveries are very indifferent now for cutters, etc. In fact nearly all the war material supplies have deliveries now that hardly improve on eight or ten weeks, which is a much poorer showing than has been made during the last few months.

PURCHASES SMALL, BUT LOTS OF THEM

Things Holding Up War Orders Are Being Ironed Out Rapidly in United States

Special to CANADIAN MACHINERY

NEW YORK, Oct. 31.—The influenza epidemic has invaded the shops of the manufacturers of machine tools as well as those of the steel plants. Production of machinery has been curtailed because of the disease. How serious is the situation may be judged from the action of the Ordnance Department in sending out telegrams to plants engaged in war work requesting operatives remaining at their tasks to redouble efforts to keep production up to the point reached before the epidemic.

Greater activity in the buying of machine tools was evident in the local market last week but most of the purchases were of relatively small lots of tools. Contracts for equipment to be installed in eastern plants to make shells and pistols are still held in abeyance, but the Lower House at Washington has finally passed the "first deficiency appropriation Bill," setting aside nearly $6,400,000,000 for war expenses. Of this total nearly $3,700,000,000 will be available to the Ordnance Department, and as soon as these funds and credits are available, large contracts for machinery will be closed.

The greatest activity in machinery buying continues to be centered in the central West, especially at Detroit, Cleveland and Chicago. The American Multigraph Co., which recently acquired the Cleveland service plant of the Ford Motor Co to manufacture time fuses for shells, is now buying shop equipment; about 300 tools will be purchased, including 100 automatic screw machines, 100 drilling machines, 50 hand screw machines, and complete tool room equipment. Many other plants in the Central West engaged largely on government work have bought and are still buying shop equipment. The Studebaker Corporation has bought turret lathes and screw machines, and is now negotiating for milling machines. There is a very heavy demand for screw machines from other sources, and 90 have been purchased, mainly by plants in the Central West, including 12 bought by the Willys-Morrow Co., Elmyra, 17 by the Steel Products Co. of Cleveland, 45 by the National Acme Co., Cleveland, and 15 by the Thomas A. Edison Co, Inc., Orange, N.J. The American Brake Shoe and Foundry Co. has purchased 16 turret lathes for its Erie, Pa., plant.

The Olds Motor Works, Lansing, Mich., will devote its entire plant to making aircraft and Liberty motors. Extensions and equipment for this plant will cost $1,250,000. The Symington-Chicago Corp., which is building a large plant to manufacture shells is in the market for tool-room equipment, including lathes, milling machines and drill presses. The Holt Manufacturing Co., which is building an extension to its Peoria, Ill., plant to manufacture caterpillar tractors and tanks, is now buying machinery.

Canadian Buyers

Canadian manufacturers who have large United States government orders are buying very little machinery in this country because under present regulations Dominion buyers may import from the United States only such tools as are unobtainable in Canada. Recent purchases in Canada include boring machines, lathes and hand grooving machines.

Shipyards and railroads are placing supplementary orders for machine tools. W. H. Gahagan Inc., Arverne, Long Island, which is to build steel tugs for the Emergency Fleet Corp., has been buying punches, drills and bending machinery for its new plant and is still in the market for portable shipyard tools. The Robert Dollar Co, N.Y., agent for the Chinese government, is buying 25 machines for rounding out shop equipment of the Shanghai Navy Yard, which will construct four 10,000-ton ships for the United States Emergency Fleet Corp. The Sun Shipbuilding Co. has purchased cranes for its Chester, Pa., plant. The Pennsylvania R. R. has taken bids on cranes for its Altoona shops and is still in the market. The Delaware and Lackawanna Western R. R. is buying a dozen miscellaneous tools for its various repair shops.

STEEL MILLS AND THE BLAST FURNACES HIT HARD BY "FLU"

Special to CANADIAN MACHINERY

PITTSBURGH, Pa., Oct. 30.—The epidemic of "Spanish influenza," or "flu' for short, is rather general throughout the east and the central west. The spread seems to depend upon climatic conditions, whereby it has not extended north beyond certain latitudes. The epidemic seems to follow main arteries of travel very largely, and to be severe in accordance with the density of population. Some health authorities have estimated that in the end 15 per cent. of the population will have been affected. As a result of these vagaries of travel some of the steel mills and blast furnaces have been very seriously affected as to their working forces, while others have escaped wholly or largely, and no general average can be struck. As an extreme case the Duquesne Steel Works of the Carnegie Steel Company may be cited, where of late an average of 15 per cent. of the working force of about 5,100 men have been off duty, absence being attributable in nearly all cases to the "flu," but managers feel that there is a disposition to attribute to the "flu" absences that may be due to some other cause, while furthermore some of the absences are due to sickness in the family, rather than to the workman himself. The next most serious case is that of the Homestead Steel Works proper, employing about 8,000 men, and with an average of fully 800 absent. Subsidiary plants, somewhat removed from the main plant, like the Shoen steel wheel department, the Howard Axle Works, etc., are much less affected. In the Shenango valley the epidemic has scarcely been felt, but the Mahoning valley has had some serious experiences.

Altogether the curtailment in production has been much less, in percentage, than the curtailment in working forces. The remaining men seem to work harder. October was expected to show a materially better production rate than the very favorable September showing, in both pig iron and steel ingots, and a rough estimate is that with the curtailment due to the epidemic there will still be shown some slight increase in the rate of production, after allowance has been made for the fact that the month contains one more working day than September, in the case of blast furnaces, and two more in the case of steel works.

Reflected Priority

The War Industries Board seems to have regarded its circular No. 4, dated July 1, but not actually circulated until late in the month, as susceptible of clear and exact interpretation, but it has developed that many, if not the majority, of manufacturers concerned have misinterpreted certain provisions, and it has been necessary to issue precise interpretations, which will materially alter the manner of securing priorities in a great many cases.

The circular provided "automatic priority" for material for a great many war contracts and activities, including, for instance, the following: Turbines, locomotive construction and repair, Fleet Corporation vessels, cranes, farm implements, etc. For these various cases "automatic priority," was prescribed, whereby the buyer, instead of securing an individual priority certificate from the War Industries Board for material, etc., desired, could place his order with merely an endorsement, by affidavit, showing that the material was for the designated purpose, and stating the prescribed priority for the activity, such priorities ranging from A-4 down to B-2.

Many interests interpreted this to mean that the priority would work all along the chain or line, in case material passed through successive hands, for instance, a shipyard could place an order with "automatic priority," and the manufacturer receiving the order could in turn order supplies, to be used in filling the order, with "automatic priority," and the second manufacturer could in turn use the "automatic priority," and son on indefinitely, as long as the identity of the material could be preserved. Such practice accordingly came to prevail in many cases.

Maurice Hirsh, secretary of the Priorities Division of the board, has lately issued a series of rulings cutting all this out. The automatic priority must work but once. The shipyard working for the Fleet Corporation, for instance, may order bolts or rivets with A-5 priority, but the bolt or rivet maker cannot order steel for his goods with an automatic priority. He must secure a priority certificate for the material direct from the Priorities Division, just as would have been necessary before the system of automatic priority was established. The bolt and rivet makers, to continue using them as an illustration, were not named as being accorded any automatic priority. Then there is another clas of cases in which the manufacturer with whom the order is placed has been accorded an automatic priority of his own. Crane building, for instance, is given B-1 priority. Thus the shipyard can order a crane as A-5, and require the crane builder to furnish the crane before he fills other orders that have lower priority or none. The crane builder can place orders for material attaching B-1 priority thereto, and he gets this same priority on all his material, irrespective of which crane order the material is used for filling.

Some of the steel mills appear to be considerably exercised over the new rulings, aserting that there will be a multiplication of small orders upon the mills, from various manufacturers who must secure individual priorities instead of lumping their orders for steel, but the War Industries Board insists that the priorities will be granted promptly, and even states that some cases may be arranged whereby priorities will be granted to cover a succession of individual orders.

More Steel Conservation

Announcements have been made of many additional agreements made between the War Industries Board and manufacturing consumers of iron and steel, whereby the operations of manufacturing consumers will be curtailed more or less. Making lawn mowers is restricted to a 40 per cent. rate to January 1, and the manufacturers are then expected to stop entirely and get into war work. The making of phonograph needles on the other hand is merely restricted to the 1917 rate. Thus there is recognition of the fact that an old lawn mower can be used over again while an old phonograph needle should not be. These agreements are altogether too numerous to summarize. Only in quite exceptional cases is there any intimation that when the restriction has been put into effect provision will be made for furnishing the steel.

Shipbuilding Activities

Recent developments in the matter of shipbuilding should not be interpreted as suggesting that there will be any decrease in the pressure to secure more ships. A batch of contracts for wooden vessels was recently cancelled, but simply because the yards were evidently unable to carry them out in reasonable time. An order for steel for a shipyard extension has been cancelled, likewise an order for steel for building a boiler plant, but these developments simply indicate that existing facilities, or facilities nearing completion, are regarded as sufficient to utilize the labor and materials available. The September completions of vessels for the Fleet Corporation amounted to 360,000 tons deadweight, a new high record, all being from United States yards except one 6,000 ton vessel built in Japan under contract. British shipyards completed over 240,000 tons deadweight in the month, making over 600,000 tons for Britain and the United States, plus the one Japanese vessel for American account. Japan also built other vessels no doubt, and Canadian building is not included.

CANADIAN SHELL SHOPS ARE BEST

That Is The Opinion of French Mechanics Who Are On Tour of District

A party of French mechanics, under the supervision of an interpreter from the Dominion government at Ottawa, has been paying a visit to some of the shell plants in Toronto during the week. The party has been in United States for some months past, going there at the request of the French government in connection with shell work. On Monday morning they were at the plant of the Russell Motor Co., where large orders for the 9.2 shells are being filled. Through their interpreter they expressed their surprise and satisfaction at the splendid results that were being secured in the Canadian plants, intimating in no uncertain way that in their opinion the Dominion of Canada shops were the last word in the speedy and accurate production of munitions.

FIRST STEEL VESSEL LAUNCHED AT MIDLAND

Successful Event Marks Progress of Industry of First Importance.

Midland — The ocean-going cargo steamer "War Fiend," of full canal size, of the modern type, was successfully launched from the shipyards of the Midland Shipbuilding Company, in the presence of a holiday multitude numbering several thousand people.

This was the first launching of the company, and incidentally the first steel vessel to be constructed in Midland, which at present is in the throes of the Spanish "flu" epidemic. Contrary to expectations, the big hulk refused to budge when the ropes were cut, the substructure of the ways having sunken into the ground during theh period the boat was being adjusted on the ways preparatory to making her initial plunge. The launching was set for 1 o'clock, but it was 3.40 before the hull started on its downward path, and in a few seconds it was all over.

The "War Fiend," built to the order of the Imperial Munitions Board for the British Government, is 261 feet long, with a beam 43 feet 6 inches, and a moulded depth of 23 feet. She is equipped with triple expansion engines, surface condensing type, developing 1,250 horse-power. She has two Scotch boilers of the marine type, and is fitted for ocean service with electric plant, cargo winches, steam windlasses, steam and hand steering gears, evaporating outfits, etc.

COMMERCIAL BUSINESS BOBS UP AS SOON AS PEACE TALK STARTS

FROM all reports that can be gathered from the large producing points in the U. S. it is certain that the only let-up in the production of iron there during the past week has been on account of the epidemic of influenza rather than from any peace talk. At the same time there are indications on the surface that the peace talk is having its effect in some places. For instance a clause has just been inserted in new ship steel contracts, which provides for the cancellation of the order by the shipping board whenever it is to the country's interest to do so. Another rather interesting feature is that as soon as there appeared to be some possibility of war work falling off, there immediately came a great grist of enquiries from many lines of commercial work that had been neglected during the course of the war. Conditions at some of the producing points in the U. S. are indicated in the following reports:

CLEVELAND. — Interest is being created here in the placing of contracts for semi-steel shells, and large allocations of war material are being made to shops that will handle these contracts. Pig iron production generally is reported by the furnace interests in this district to be considerably ahead of the record breaking rate of September.

NEW YORK.—It looks as though the war shops were going to be in favor after the war with the producers of iron just as much as they are now. The number of contracts that are being placed here now for 1919 are plainly giving favors to those shops that are certain to have good business prospects in the trade after the war work is over.

PITTSBURGH.—There is a move being made here to the end that the War Industries Board or some such organization should be continued for some period at the expiration of the war order business. Both the consumers and producers of material seem to feel that they will need some court of resort in order to secure fair prices either for buying or selling.

BUFFALO.—A questionnaire has been sent out by the Government to holders of pig iron in this country, and it is quite searching in its provisions—one of the results is that it is quite certain that a number of the users of pig iron had over-estimated the amount that they would require, doing this in order to make sure that their deliveries would be up to the needs of their shops. These figures are being promptly cut down and a good deal of material is being released in this way.

CHICAGO.—Some of the 1919 contracts that are being filled out here at the present time have a number of clauses in them which seek to protect both ends of the trade For instance it is provided that if the Government cease to fix maximum prices at any time, the last maximum price is to be paid for the remainder of iron shipped on the contract. The buyer is given the privilege of cancelling at any time the price is not satisfactory, and the seller reserves the right to cancel if the price fixed is below the cost of production.

ST. LOUIS.—Most of the makers of pig iron in this district have classifications of essentials that will take their output for some time to come. One effect of the peace rumor though has been to stimulate enquiries from the non-essential consumers. It has been brought out very forcibly that there is enormous amount of late business waiting to be executed the moment iron is released to go into it. Building which has virtually been at a standstill for many months is expected to revive the moment materials are available.

THE STORY OF A POUND OF COAL

(Continued from page 516)

of 1 pound of pure water 1 degree Fahrenheit, at or near its maximum density, 39.1 degrees Fahrenheit. One B. T. U. is also equivalent to 778 foot pounds of energy; or 1 B. T. U. per hour = .000293 kilowatt-hour, also 1000 B. T. U. per hour = .293 K.W. hour). Having this quantity in mind the per cent. loss in each apparatus is readily judged as we progress from right to left or reference to the following table prepared by Mr. Scott gives these percentages directly.

Thus we see where the energy in the pound of coal goes to before it finally reaches the switch-board bus-bars. In other words, starting with 100 per cent of energy in the coal when placed in the fire-box, we eventually throw away nearly 90 per cent. of this energy, or to be exact 89.7 per cent., and deliver to the electrical system only 10.3 per cent. of the power we started with, when we lighted the fire in the boiler.

If we operate electric motors from this electrical energy we fare quite well, as the motor has an efficiency of from 80 to 90 per cent. or more, depending upon the size. That is, the motor converts say 90 per cent. of the electrical energy put into it into mechanical power at the pulley. But in converting the electrical energy into radiant light we find that the most efficient of all incandescent filament lamps—the tungsten lamp—only realizes about 5 per cent. efficiency, and requires about 1 watt per candle-power. Thus of the electrical energy put into the lamps we only receive five per cent. in the form of radiant light,—the other 95 per cent. is lost. Lost, all because we of to-day do not know enough to more efficiently convert electric current into radiant light. At the present energy consumption of 1 watt per C. P. for a tungsten lamp and figuring on the perfect transformation of the energy in one pound of coal, viz., 14,150 B. T. U. we would get (14.15 x .293 kilowatt-hour = 4.14 K.W. hr.) 4,145 candle-power, as represented by the large lamp at the right of the illustration. As a matter of fact we only manage to get 1.45 x .293 K.W. hr. or .424 kilowatt-hour, owing to the nearly 90 per cent. loss in the steam-electric generating system. This results in 424 candle-power, as represented by the small tungsten lamp at the left of the illustration, based on 1 watt per candle-power.

The over-all efficiency of the entire system, from coal burned to radiant light is thus seen to be 10.3 per cent. multiplied by 5 per cent. or .51 of 1 per cent.; or a little over one-half of 1 per cent.! Think of it! All we get out of the coal, no matter how much we burn, is a paltry one-half of one per cent. One immediate remedy for this wasteful system of utilizing coal as a source of energy is the mouth-of-mine plant. These electric generating stations, placed at the mines, eliminate all carting and hauling of coal and permit the high tension electric current produced to be transmitted hundreds of miles at very high efficiency.

ANALYSIS OF AVERAGE LOSSES IN CONVERSION OF ONE POUND OF COAL INTO ELECTRICITY

No.	Part of Plant.	B.T.U.	Per cent.	B.T.U.	Per cent.
1.	B. T. U. per lb. coal supplied	14,150	100.00		
2.	Loss in ashes			340	2.4
3.	Loss to stack			3,212	22.7
4.	Loss in boiler radiation and leakage.			1,181	8.0
5.	Returned by feed-water heater	441	3.1		
6.	Returned by economizer	960	6.8		
7.	Loss in pipe radiation			28	0.2
8.	DeDlivered to circulator			223	1.6

THE LAPPING BENCH

Making Thread Gauges

By T. H. FENNER
Associate Editor

IN the manufacture of shells, it is important that extreme accuracy be maintained in all fitted parts and particularly where screw threads are concerned. The making of thread gauges is therefore, a job that calls for the highest amount of precision, all sharp edges are honed off, and ehe gauge may pass the rigid tests called for by the various governments using them. It is pleasing to be able to state that in this highly specialized work, Canada is taking a worthy share, and Canadian firms are making gauges for the Imperial Munitions Board. The Reliance Tool & Motor Co., of Toronto, have been highly successful in this line of work, and a description of their plant and methods will be found of great interest to any one connected with the munition industry, and to toolmakers and machinises, generally. The types of gauges handled by this company include the Marks II Fuse-U.S. 155 m.m. and 75 m.m. adapter, 155 m.m. and 240 m.m. shell, and Booster Casing Mark III thread gauges.

The List of Operations

In making the ring gauge quite a number of operations are necessary, seventeen in all. They are arranged as follows:—

1.—Cut off stock in Power Saw.

2.—Rough Bore Hole.

3.—Put on Arbor, and take cut off dia. and sides.

4.—Place Gauge in oil tank at 500 degrees F., and leave 12 hours.

5.—Anneal.

6.—Finish bore hole and face one side.

7.—Finish face both sides, and rough thread within 1-32 inch of original dia.

8.—Carbonize and have soft.

9.—Finish thread and face to width.

10.—Cut slot in gauge.

11.—Harden.

12.—Rough grind to within .005 of size and allow to stand 48 hours.

13.—Final rough grind on finisher and have stand 24 hours.

14.—Finish grind to size.

15.—Grind root diameter and face. Have all sharp edges of gauge.

16.—Check.

17.—Marking.

The operations for making the internal gauge are somewhat different, so for instance, instead of operation 2 being rough boring hole, as in the ring gauge, it would be rough turn. After rough turning the heat treatment takes place, following which comes the first thread cutting. Here we find something novel in the manner this is carried out.

Cutting The Thread

The tool used for this operation is a Le Blond heavy duty lathe, fitted with a precision lead screw. It will be noticed from the illustration that the tool is in the inverse position to that usually found in turning operations. That is to say, that instead of the cutting edge of the tool being on the top, and the job turning towards the operator, the tool is placed with the cutting edge down, and the job turning away from the operator. This method has been adopted as leading to best results in the class of work done. In cutting a thread in the ordinary way, with the very fine clearances used in the tools, it was found that small chips were apt to collect on the top of the tool, and the motion of the job would carry them down between the tool and the thread, making a ragged thread, and in some cases breaking a piece out, the result being a scrapped gauge. By turning the lathe backwards, and turning the tool upside down, the chips all drop clear, and it is also found that all tendency to chatter is eliminated. The error in the lead screw in these lathes is about .0004 in 5 inches, so that in the length of the thread that is cut, about 5/8 inch, the error is not perceptible.

CUTTING THE THREAD ON CHECK GAUGE

The Heat Treatment

The heat treatment between the operations of rough boring or turning, and the finish boring or thread cutting consists of a 12 hour soak in the tank containing oil at 500 degrees F. After coming out of the oil bath, the gauges are put in a pot, placed in a furnace, and brought slowly up to a temperature of 1320 degrees F., after which they are allowed to cool down to atmospheric temperature before removing from the box.

Finish Boring Operations

The finish boring operation is performed on Le Blond engine lathe, a standard undersized reamer being used. After boring, one side is faced. The gauge is then placed on an arbor and both sides faced in the lathe, after which they are taken off the arbor, and the thread is rough turned to within 1-32 in. of the original diameter. Carbonizing is the next operation, the gauges being left soft. After this the thread is finished in the lathe, and the gauge is faced to the finish width.

Cutting The Slot

The final machine operation to be performed on the ring gauge is the cutting of the slots. There are three of these, as shown in the sketch. The three slots are cut with a very fine saw, and then the hole is drilled and tapped for the adjusting screw. This screw is for the purpose of making adjustment to the amount of the slot opening. After the gauge is finally adjusted, a liner is placed in the slot, and the screw is sealed to prevent tampering. The gauge is then hardened.

Grinding Operations

The first operation after hardening is to rough grind to within .005 of size, after which the gauge is allowed to stand for 48 hours, for seasoning. A final rough grind is then made, and another 24 hours seasoning allowed to interpose, before finish grinding to size on outside. The thread is then ground to root diameter on thread grinding machine. The final operation is marking with size, firm's name, etc. This is done by etching.

FINISH GRINDING THE THREAD

Limits Allowable

The limits allowable in this work are extremely fine. An example of this is shown by the following specification for the United States 32 thread per inch Right Hand Gauge.

Pitch Diameter = 1.480—.0002.

½ Angle=30° plus or minus 20 minutes

Lead=plus or minus .0002 in. in .22 in.

This allows for the pitch diameter only two ten thousandths, and for the lead two ten thousandths either way, or four ten thousandths in all. The allowance in the angle of the thread is 1.1 per cent., so it can be readily understood that extreme care is necessary in each operation.

All lapping operations are performed by hand, and the illustration shows the corner of the shop devoted to the lapping benches.

Some Details of The Work

Another interesting detail shown here is setting the tool for cutting the thread on the plug gauge. The photograph illustrates this very clearly. As can be seen, a clamp is the lathe and a pair of callipers clamped onto this by one leg. On the other leg is clamped a spring indicator, registering in ten thousandth parts of an inch. A stop is placed against the tail stock of the lathe, and the carriage is brought back against the stop by the screw. The tool is then in contact with the indicator, at the cutting end. The carriage is then moved clear of the stop, and the tool holder moved in to the job till the back of the tool is in line with the indicator. The carriage is moved back onto the stop, when the

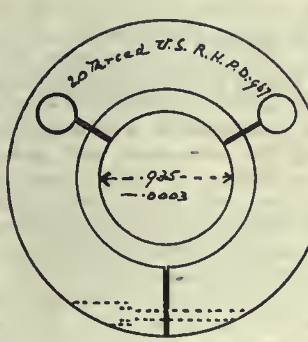
SETTING THE COMPOUND REST

back of the tool will be in contact with the indicator. If the reading is the same in both positions, then there is no doubt of the perfect alignment of the tool, and the thread can be cut without fear of error.

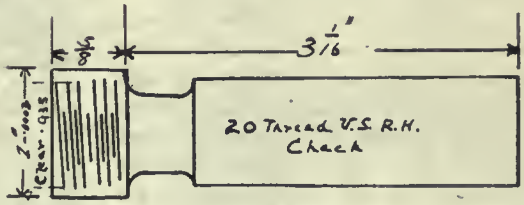
Setting the compound rest of the lathe to get the correct angle for the cutting tool is an interesting job. The illustration makes it perfectly clear. An angle plate is bolted on to the face plate of the lathe. This angle plate is perfectly square being lapped all over. A protractor with an attachment for a straight edge is clamped on to the angle plate, the protractor being marked in degrees and quarters, and a vernier mounted on the protractor reading minutes. A dial indicator is mounted on the tool post, and the spindle of the indicator brought in contact with the straight edge. By moving the rest in and out along the straightedge, and watching the indicator, any error over .0001 of an inch can be detected.

A Good Word For the I. M. B.

The Reliance Tool and Motor Co. had been making and shipping gauges to the U. S. before handling any Canadian business. On the suggestion of the War Trade Board that Canadian business should be looked after before exporting the firm got in touch with the Imperial Munitions Board, and received enough orders to fully occupy them without looking any further afield. In this connection they received very valuable help from the inspection department, headed by Capt. Durley of the Imperial Ordnance Dept. at Ottawa. While it is, for well understood reasons, impossible to go into details, it may be said that it was always possible to get the ungrudging help of Capt. Durley and his staff when any information was required that it was in their power to furnish, and this without any expense to the company. While we



RING GAUGE



CHECK

often hear complaints of red tape, etc., in connection with government work, it is pleasant to hear the expressions of appreciation from a firm engaged in such difficult work, for assistance and advice so heartily given.

The Personal Factor

The man who has built up this highly successful business is Mr. Thos. L. May, of Toronto. Mr. May is a thoroughly practical man. He started his career as an apprentice to the Bertram Engine Works, Toronto, building engines, in 1896. He remained with them until 1900, when he went to Niagara Falls, with the Usher Wease Co., of Switzerland, where he was engaged on the installation of the first Hydro electric power stations. He remained with them about three years, and incidentally, first came in touch with the metric system. From there he went to the Waterbury File and Machine Co., where for two years he was in their tool making department. On leaving them he came back to Toronto the Toronto Silver Plate, in the tool room, having previously taken a correspondence course in mathematics. He later took charge of this department. He remained with them for about 3 years, and then started a small jobbing shop in Toronto, at 126 Adelaide Street, where he made the metallic but-

METHOD OF ADJUSTING CUTTING TOOL

tons for the militia uniform tunics, probably the first made in Canada. He then went with the Brandon Shell Co., now defunct, making the 45 shell, and in 1915 started the present company in conjunction with Mr. Geo. S. Brintnell. In March 1916 Mr. Brintnell retired, Mr. May taking over most of his interest, and since then has carried on the business in association with Mr. W. H. Newman, of Rowen Jones & Somerville. For about 1½ years has been making thread gauges, and has achieved a market success, not without much persistent work and worry. Mr. May personally superintends the manufacture of the gauges throughout. In speaking of his success, Mr. May gives great credit to the organization he has gathered about him, for their personal interest and attention to the various operations covered in the making of a highly finished product.

FACE GRINDING PLUG GAUGE

CONVERTING A GROUCH

By J. James

A few days ago an engineer remarked to me, "These engineering journals make me weary." Said I, "What special ailment is bothering you now, my friend?" He elucidated somewhat as follows:

"The editors come at a fellow and call him down because he will not write about how he overcame some difficulty in connection with his work. They say, never mind if your sketch is crude and your letter shy on correct grammar, writing or spelling, we will polish them up for you, it is the idea we want, and we will cash up for that same idea, telling how you won out and so forth and so on. There am I taking their advice and using up my postage stamps, time and stationery to help them out, and every time my letters come back, not because they are not good enough, so reads their printed notice enclosed with the returned letter, but because they are not suitable for the journal. How do I know what will suit them? I send them power plant experiences all right, dang it all, my experiences are just as good as some of those I see in print, and better than a lot of them." At this point he paused, but before he got started on the second lap I cut in. "Will you allow me to throw some talk for awhile? I have written many hundreds of letters for these journals you talk about and have received cash for many of them; I have also had many of them returned as being unsuitable, perhaps the ideas therein were old and had been printed several times without my knowledge, in fact on two occasions when I thought I had solved some particularly difficult problem the editor made a note directing my attention to where practically the same idea had been printed many moons before I had sent in my MSS.

"Another way to look at things is this: The editor is the buyer for the publisher; he is paid for what he knows about goods that will give satisfaction to the publishers' customers; these are the subscribers as a whole, he is responsible for the material dished out in the editorial or reading pages. He does not want to tell a customer, who is trying to sell him some stale goods that the said goods are out of date, he just sends on a polite printed note letting him down easy, and perhaps the note contains a carefully hinted suggestion to try and bunco some other editor who may prove an easy mark." At this point I started talking again before my friend could do so.

"Suppose a traveling salesman for some goods of which you had a big stock on hand, called on you and insisted you buy more of the goods just because they were good, the fact that you did not want any more of them making no difference to him, what would you do, would you give in to him and buy something you did not want with your nice handy cash just because he thought he knew your business better than you did yourself?

"Perhaps you are in the same class, trying to sell something the editor has enough of or has had enough of. Try again, perhaps your next near original idea will catch him unprepared, and he may cause your chest to swell and your heart to throb when you receive his check for a whole lot of dollars, perhaps as many as two, but never forget he is the buyer and you the seller. If you cannot think up something original try and put a disguise on it and make it look original (this is my advice, not the editor's. I bet he won't print it), perhaps you may get by with it. An editor is only human—you may not believe this but it is true, so if you stick to it long enough you are bound to get him some day and receive enough coin to pay for all the stamps and stationery you have used up in the past."

"Dang it," said my friend. "I thought I could talk, you are it, take some advice from me, quit engineering, go sell books, you will make a fortune. No one could choke you off. Say, I believe you have done me good, anyhow, I'll think better about those editor fellows, especially do I pity them if they have to watch out for fellows like you if you write as fast as you gas."

SPOT WELDED BRAKE HANGERS

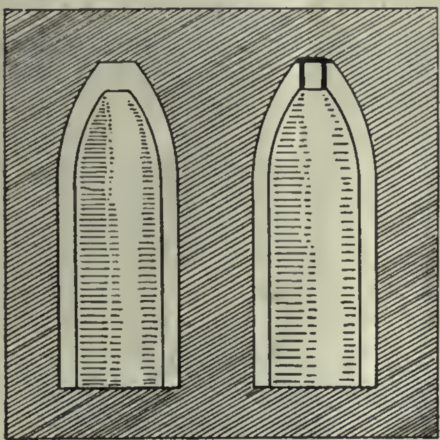
The Portland Railway, Light and Power Co. finds that the half-ball brake hangers used on its Brill trucks can be repaired by spot welding. The repair costs less than a new part (besides eliminating delivery delays), and the repaired parts have longer life than the new equipment. The worn parts are sorted according to their condition and repaired to fit corresponding gauges.—"Electric Railway Journal."

GAS RIVET HEATERS

At the Bethlehem Shipbuilding Corporation's Alameda Works, U.S.A., gas is henceforth to be used exclusively for rivet heating, plate-bending, and general fabricating heating purposes. This is a radical departure from the shipbuilding methods that have been in use for years, whereby it was thought that only coke could be used—even oil was considered an innovation. Good work by a riveting crew depends to a great extent on properly heated rivets. With a continuous and uniform gas forge the heater man can give his undivided attention to regulating the forge so that there will be no burned or overheated rivets, irrespective of the speed at which the crew works. This tends towards regularity, with properly upset and tight, full-headed rivets as a result. The cooling contraction is likewise more uniform, and caulking is reduced to a minimum.—"Chemical and Metallurgical Engineering."

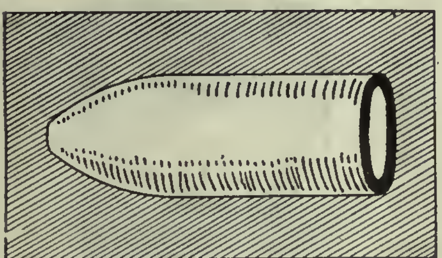
Machining Nine Point Two Shell and Adapter

The Various Machining Operations Are Described and Illustrated in Detail—To Machine the Shell Requires Twenty-four Operations—While to Turn Out the Adapter Nine More Are Necessary



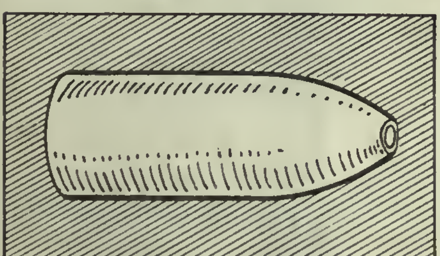
OPERATION NO. 1

DRILL AND ROUGH FACE with drill press and revolving table with expanding mandrels for two shells or radial drill with stationary mandrels.



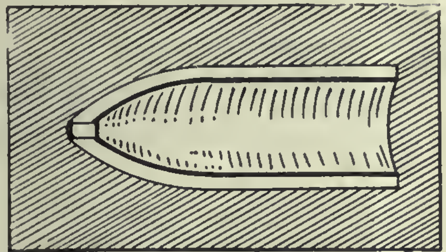
OPERATION NO. 2

CUT OFF OPEN END with special single purpose machine (two tools opposite each other cutting towards the centre.



OPERATION NO. 3

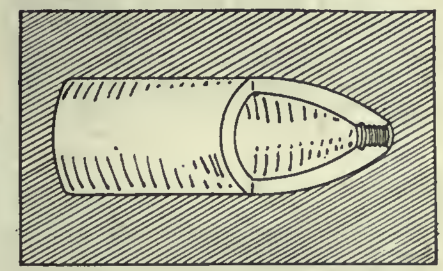
ROUGH TURN OUTSIDE with lathe having one carriage and face cam profiling attachment or with lathe equipped with two carriages one for straight part of shell and the other for the radius. Shell held on expanding mandrel.



OPERATION NO. 4

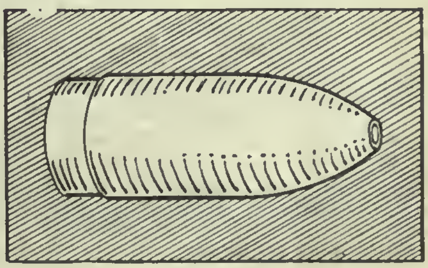
BORE single (internal) radius shells with single pointed tool with face cam profile attachment on boring lathe.

For single or double (internal) radius shells, two cutters for roughing straight part, two profile roughing blades and two profile finishing blades - three separate and interchangable boring heads. The shell is held in a clamp chuck.



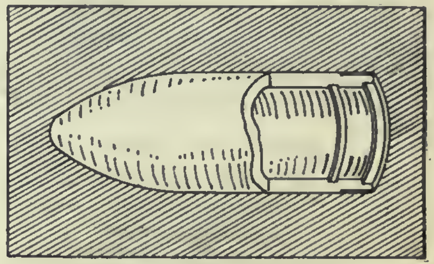
OPERATION NO. 5

FINISH FUZE HOLE with boring recessing, angle facing tools, shell reamer and colapsable tap in turret lathe. Shell held on expanding mandrel.



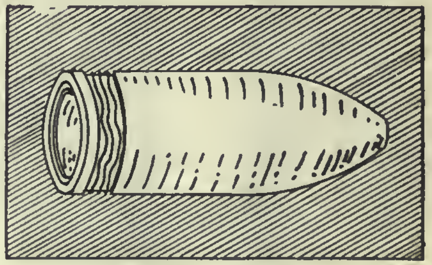
OPERATION NO. 6

FINISH TURN with single pointed tool on lathe with face cam profiling attachment. Shell held on expanding mandrel.



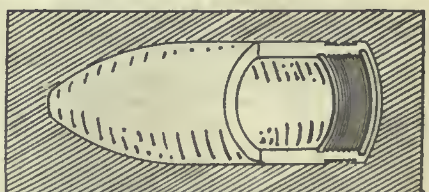
OPERATION NO. 7

COUNTERBORE AND RECESS BASE END with roughing and finishing counterbore tools and recessing tool in turret lathe. Shell held in three jaw floating ring pot chuck and plain three jaw steady at base end.



OPERATION NO. 8

GROOVE AND WAVE, special single purpose machine or lathe with attachment (face cam and etc) for cutting waved ribs with tools for roughing and undercutting. Tools in turret or four way tool post. Shell held on expanding mandrel.



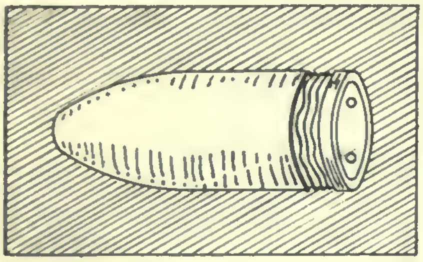
OPERATION NO. 9

THREAD BASE END, shells up to 9.2 and inclusive, colapsable tap on drill press, shell held in hinged clamp chuck.

Or special single purpose thread miller.

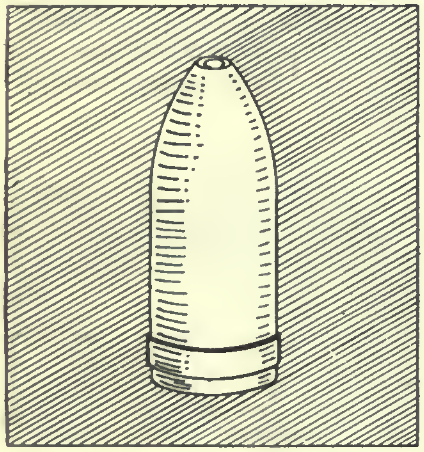
OPERATION NO. 10
PRELIMINARY SHOP INSPECTION

OPERATION NO. 11
PRELIMINARY GOVERNMENT INSPECTION.



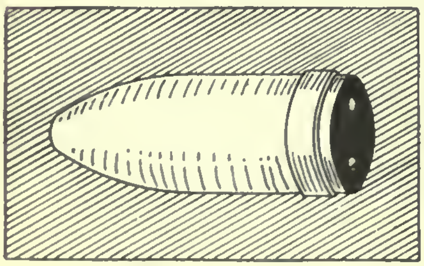
OPERATION NO. 12
FIT ADAPTER by hand.

OPERATION NO. 13
SCREW IN ADAPTER with special power driven screw driver or with hand wrench, shell held in floor clamp.



OPERATION NO. 14
APPLY BAND when hot after annealing in special electric heater or gas furnace. Band applied by special banding press.

OPERATION NO. 15
WEIGH on standard scales.



OPERATION NO. 16
FACE BASE TO WEIGHT with standard turning tool on lathe. Shell driven by centre screwed into nose threads. Shell supported at base end by roller-steady.

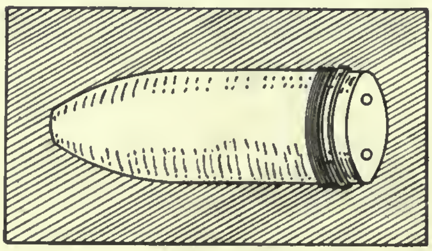
OPERATION NO. 17
CHECK WEIGHT on standard scales.

OPERATION NO. 18
STAMP BASE, with fixture to hold stamps in proper position clamped over base of shell. Hand hammer used for stamping. Shell held (at balancing point) in tilting cradle on bench to facilitate easier use of hammer.

OPERATION NO. 19
WASH AND CLEAN Shells are lowered into a tank of hot water and alkali thoroughly rinsed and then allowed to dry.

OPERATION NO. 20
VARNISH (depending upon specifications). If after adapter has been inserted, a special varnish spraying machine with traveling nozzle and roller cradle for revolving shell or by means of a small varnish spraying gun mounted on a board held in a slide. Shell revolved on belt driven rollers when varnish gun is being slid in and out of shell. Gun is fitted with nozzle to suit depth of bore in shell.

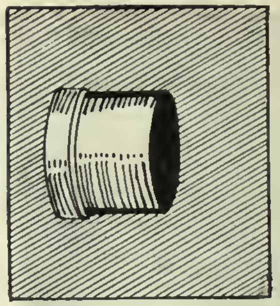
OPERATION NO. 21
BAKE VARNISH (at specified temperature) in special electric heaters or in gas oven in the later case the shells are placed base down on trucks of suitable size and run into oven on a track.



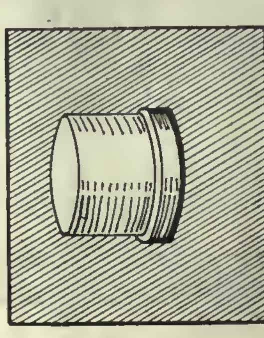
OPERATION NO. 22
TURN COPPER BAND on special single purpose machine or lathe with carriage equipped with special tool holders and tools, two single pointed tools for trimming band to width, rough form turning tool and finish form shaving tool. Shell is held on lathe by expanding mandrel.

OPERATION NO. 23
FINAL SHOP INSPECTION

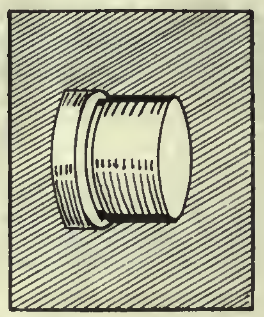
OPERATION NO. 24
FINAL GOVERNMENT INSPECTION.



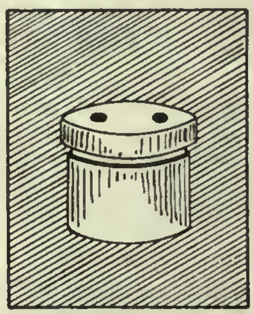
OPERATION NO. 1
ROUGH TURN AND FACE BODY on lathe. The adapter is held by its flange in a three jaw universal chuck.



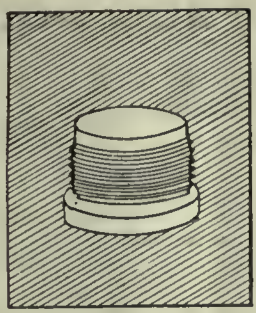
OPERATION NO. 2
ROUGH TURN AND FACE FLANGE on lathe. The adapter is held by its body in a three jaw universal chuck.



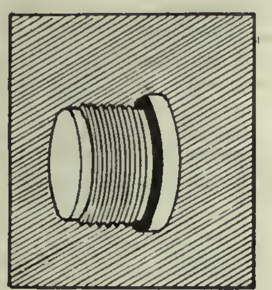
OPERATION NO. 3
FINISH TURN BODY AND RECESS on lathe. The adapter is held by its flange in a three jaw universal chuck.



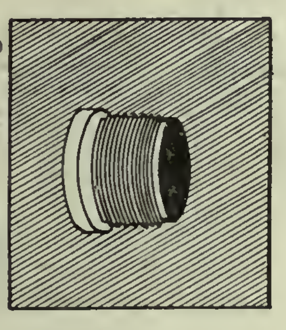
OPERATION NO. 4
DRILL WRENCH HOLES on drill press. The adapter is held by its body in a box (clamp) jig.



OPERATION NO.5
CUT THREADS on drill press with self opening die. The adapter is centered by its flange and held by dowel pins in its wrench holes. If a special thread miller is used for this operation the wrench holes may have to be tapped before this operation to hold adapter in the miller and re-drilled afterwards.



OPERATION NO.6
FINISH TURN AND SQUARE FLANGE on lathe. The adapter is held by its threads in a three jaw (threaded to suit adapter) universal chuck.



OPERATION NO.7
FINISH TURN AND FACE PILOT on lathe. The adapter is held as in the sixth operation but with its pilot outwards.

OPERATION NO.8
FINAL SHOP INSPECTION.

OPERATION NO.9
FINAL GOVERNMENT INSPECTION.

UNUSUAL LUBRICANTS

By M. M.

The problem of lubrication is by no means simple and its complexity has been pointed out on many occasions. Lubrication is conditioned by many circumstances.

A spindle from the machine and likewise the bearing in which it is carried have surfaces which consist of circumferential grooves. These are minute, but until the surface more nearly approaches a perfect cylinder, a new bearing requires unusual care until run in, otherwise until the hills have been abraided to the level of the valleys. It is by no means well known that longititudinal drawfiling with a dead smooth file has, before to-day, restored running conditions in a bearing which would not behave. For large spindles such treatment is beneficial before erection and is seriously recommended. Since it will restore a bearing which persistently runs warm to a sense of due behaviour, it is worth more general adoption.

There are instances where a big job must be kept running at all costs with a hot bearing, and playing a hose on the same may dissipate the heat, but does not remove the conditions; leading as it does to very rapid wear.

There are a few simple prescriptions all of them tried and found successful, which have restored a hot bearing to good running conditions, when shutting down was impossible. Heavy doses of castor oil and minute alterations or injections of distilled water, to induce saponification, is one remedy. Graphite and lubricating oil is another. The worst cases are those in which a steel spindle runs in gun-metal, and there is no remedy to compare with flour of sulphur mired with lubricating oil; it acts like a charm in most instances, and is strongly advised.

Cast iron sliding on cast iron gives in time a surface skin whose co-officient of friction is very small, and such skin is not easily broken. When this surface is abraided, the conditions are rather startling, for actual red hot sparks commence to fly in a very short time, and lubricating oil simply burns to a carbon deposit, and has no effect whatever. Putty white lead, mixed with lubricating oil, has been successfully used to cure even these conditions. The most unusual lubricant which came under personal notice and experience was used in the thrust bearing of a steamer, and han been utilized there for many years. As is well known, the type of bearing has a large enclosed volume which can serve as a bath. This was filled to axis of shaft with a solution of soft soap in distilled water, about 1 cwt. of soft soap sufficing for six month's use. The entire contents were occasionally changed, and a daily feed of about ½ pint of strong solution added. The bearing never gave trouble unless a new greaser started to oil it, when its temperature increased in direct ratio to the amount of oil.

When a bearing gets hot, the metals are in intimate contact, and the normal film is broken down. The remedies noticed restore conditions by the interposition of a more durable film between the surfaces. They give an artificial skin to the bruised surfaces, and allow gradual restoration of its condition.

Unlike the nigger doctor, who gave rosin and alum for a broken limb—the last to draw the bones together, and the first to stick them—the remedies, although perhaps not scientific, are successful. A word of caution is perhaps advisable—don't follow Mark Twain in his cure for a cold, and mix the remedies —give one a chance before trying another.

Finally, the remedies here noticed are known to, and practised by, marine engineers, and they have before to-day, kept the job running when a shut down on a lee shore would have meant disaster. This last for the sceptic who may be inclined to doubt their efficacy.

The Jeffrey Manufacturing Company have issued a catalogue No. 175 on the subject of belt conveyors which will prove of value to the manufacturer, engineer or contractor having to do with the economical handling of materials. A department from the usual catalogue has been made in that the subject of belt conveyors is treated from a strictly engineering standpoint and the purchasers requirements for information regarding capacities speeds, etc., are fully met.

Early types of belt conveyors are treated of as an interesting historical sidelight and the various improvements which followed a desire for better service follow in order. Some idea of the scope of the belt conveyor and of the many industries using it is given in a chapter devoted to the various industries and their use in detail of the belt conveyor.

Little information is available regarding the engineering design of belt conveyors and the portion of this catalogue which gives, condensed data for the engineer, belt tension and horse-power pull, general tables of belt capacities, belting facts in widths, plys and covers is of timely interest and should prove of high value to those having to do with the design of conveyor installations. Other subjects treated of are, protecting the life of the conveyor belt, curve of belt from horizontal to incline, various forms of belt conveyor drives, spacing of conveyor parts for best service, methods of loading and unloading belts and rules for installing conveyors. This catalogue is being issued through the Montreal office of the Jeffrey Manufacturing Co., Power Building, Montreal.

Company Can Build.—The Cluff Ammunition Company, of Toronto, made application for the use of a building at Atlantic avenue for the storing of shells, at the meeting of the Property Commission. It was explained that it would only be used during the war and torn down after the war. The application was granted.

Tooling Up Single Spindle Automatics and Lathes

Tooling For British 101 Fuse Body—Importance of Gauging—Method of Gauging—Planning Sequence of Operations to Enable Limits to be Easily Adhered to—Reducing the Poor Work

THE demand for accurate and rapid production of parts from bar steel has caused an increased need of experienced mechanics as designers, tool setters and head operators.

The particular part referred to in this article is the British 101 fuse body. Fig. 1 shows the first operation and the final tooling that was arrived at and which secured the best result. The operation being carried out on a No. 4 single spindle Gridler automatic. The sequence of this operation is worthy of note, the manner in which the rough and finish forming, and the drilling was accomplished.

The actual gauges necessary to check the work performed in this operation are illustrated in Fig. 2. The gauges were designed along lines that would advance and secure rapid and accurate inspection, as it must be born in mind by the mechanic, that this is most important, first, inasmuch as the gauging is an expensive necessity both from the viewpoint of operation and the gauges themselves, second, that should incorrect work be permitted to pass inspection that owing to a latter check its rejection would mean additional expense in time wasted.

Fig. 2A, shows the fuse body after the first operation, the gauges being used marked across each dimension line.

The second operation that of reaming, drilling and rough facing to length, was carried out on a similar machine and is illustrated by Fig. 3. The method of gauging to determine as to whether or not the piece is within the required limits is shown in Fig. 4.

Fig. 4A shows the fuse body after the second operation, the gauges used being marked on the dimension lines. Gauges R. 112-II. determines the proper length of the core.

The third operation, that of shaving grooving, knurling, recessing and chamfering is illustrated by Fig. 5. It being a good example of the type of work which can be performed on a turret lathe.

Fig. 6 shows the gauges used after this operation. Attention is called to the comparative few number of gauges required, although the operation is not what might be called simple.

Fig. 6A shows the fuse body after this operation, the gauges being marked on same as previously noted in the first and second operations.

The illustrations explaining the various operations can be carried out in similar manner on various components, the principle being identical and in keeping with general practice.

As previously pointed out the method of gauging to be employed must be considered at the offset and laid out to determine a simple and accurate means of securing the required results.

In planning similar operations close limit requirements on certain dimensions must be considered and the sequence of operations so arranged that such dimensions, or rather their limit, can be easily and readily adhered to. The mechanic in charge and responsible for the work of a battery of machines must have or rather will be in a far

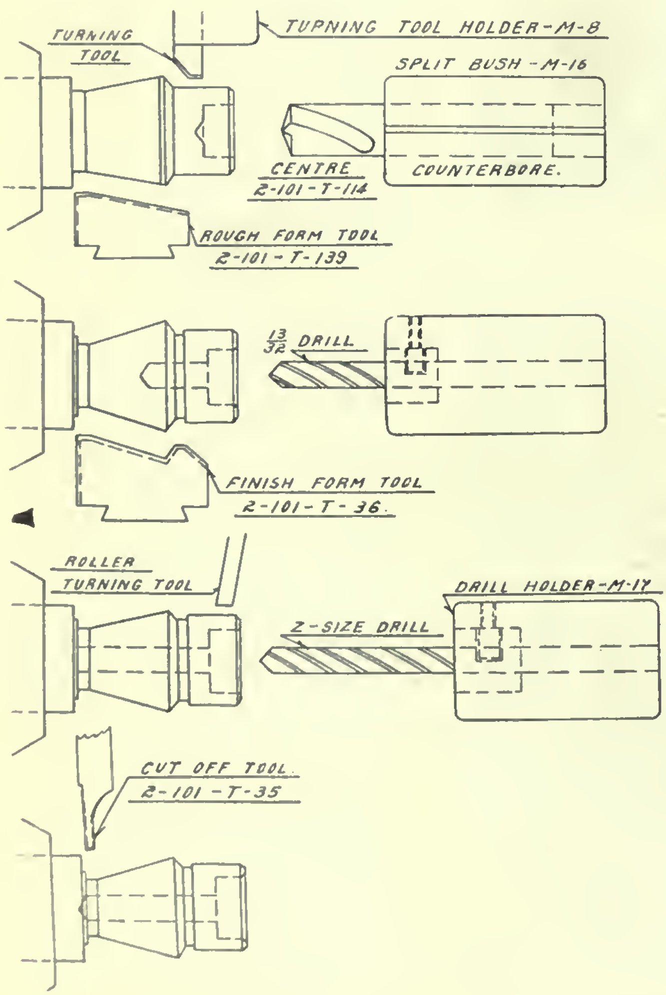


FIG. 1

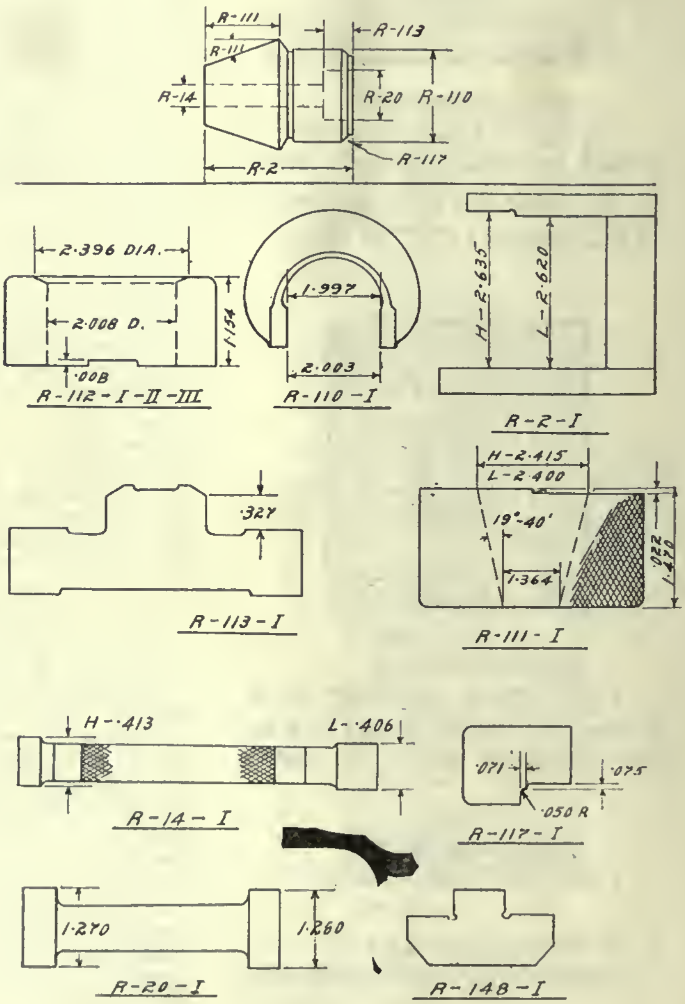

FIG. 2

better position to secure the desired results if he is familiar with the whys and wherefores of the planning of his operation in hand.

In order to reduce the amount of poor, scrap and what is termed salvageable work, a control inspection should be installed. This consists of the gauging directly of each indivdual machine during certain appointed hours or intervals. By such means the poor work can be reduced to a minimum and correctly before any great amount of similar work is produced.

Methods, Machining Devices, Systems and Suggestions From Shop And Drafting Room

BENDING PUNCH AND DIE FOR MAGAZINE PLATE

By F. SCRIBER

The accompanying ilustrations, Figs. 1 and 2, show an assembly drawing and details respectively for bending up the edge X on the rifle magazine plate shown in Fig. 3. This plate is previously blanked out to shape and has the holes shown punched in it. In this operation it is located on two pins A, Fig. 1, although these pins are not depended on to keep it in position while bending as it is backed up along the edges X and Z, which are opposite the bend by solid metal which conforms to the outline of the magazine plate. This die is of the spring pad type, the spring pad is indicated as C. This spring pad fits in the centre of the die blank D, and the punch E in conjunction with the die block and spring pad are the chief features of this tool and are what actually performs the bend.

Before describing just how this bend is performed it is first advisable to more completely describe the construction of

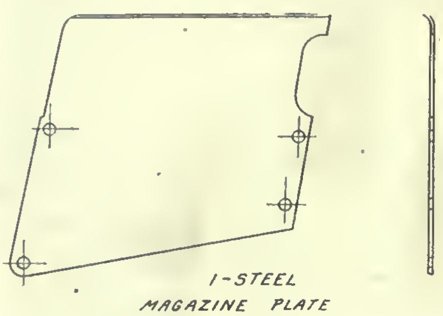

FIG. 3—MAGAZINE PLATE

the die. The punch E is held by screws and dowels to a punch holder F, this punch holder fits into the ram of the punch press. In the punch E two holes G, are drilled, these are clearance holes so they will not interfere with the pins A, while the punch and die are in operation. The die block D, is likewise held to the die holder H, by screws and dowels and in this die block four springs are provided. These springs enter the spring pad and are backed up by screws J. The spring pad is free to slide up and down in the die block it being prevented from coming up more than the desired amount by the flange on the spring pad at K.

In bending this piece the flat magazine plate is placed on top of the spring pad, the top surface of this spring pad being at this time slightly above the top surface of the die. It is located on the pad and is backed up by the solid metal as previously described. As the ram of the punch press descends the magazine plate is firmly jammed between the punch and the spring pad and as the punch continues down it carries the spring pad with it and thus the edge of the magazine plate is curved up by the die as indicated at X in the lower right hand view of Fig. 2. As the ram of the punch press ascends the spring pad carries the magazine plate or work up and the work may thus be easily picked off the top of the die. A slot Z, is cut across the end of the pad so a hook may be used to pick the work off the pad. The parts shown on Fig. 2 are

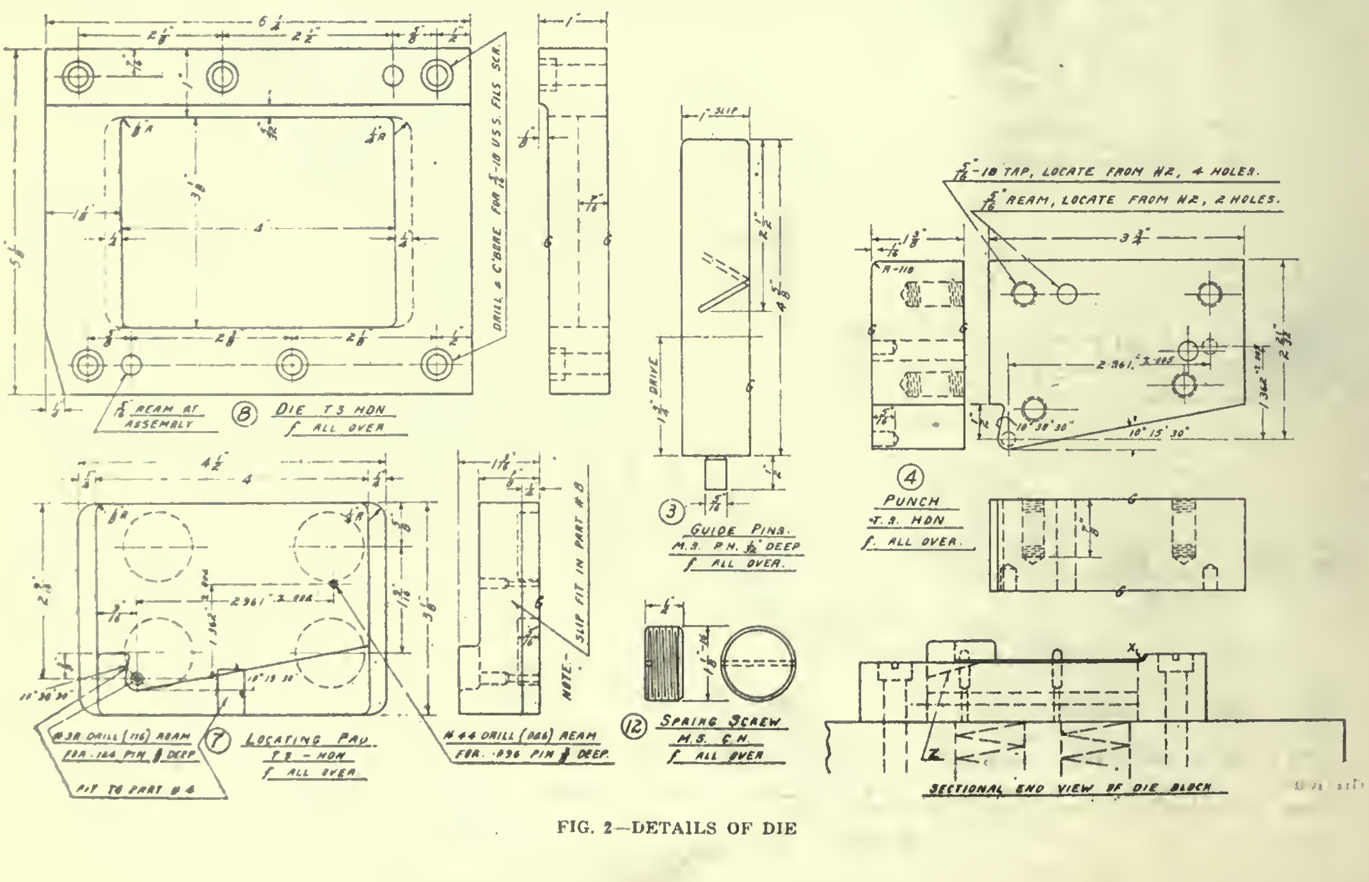

FIG. 2—DETAILS OF DIE

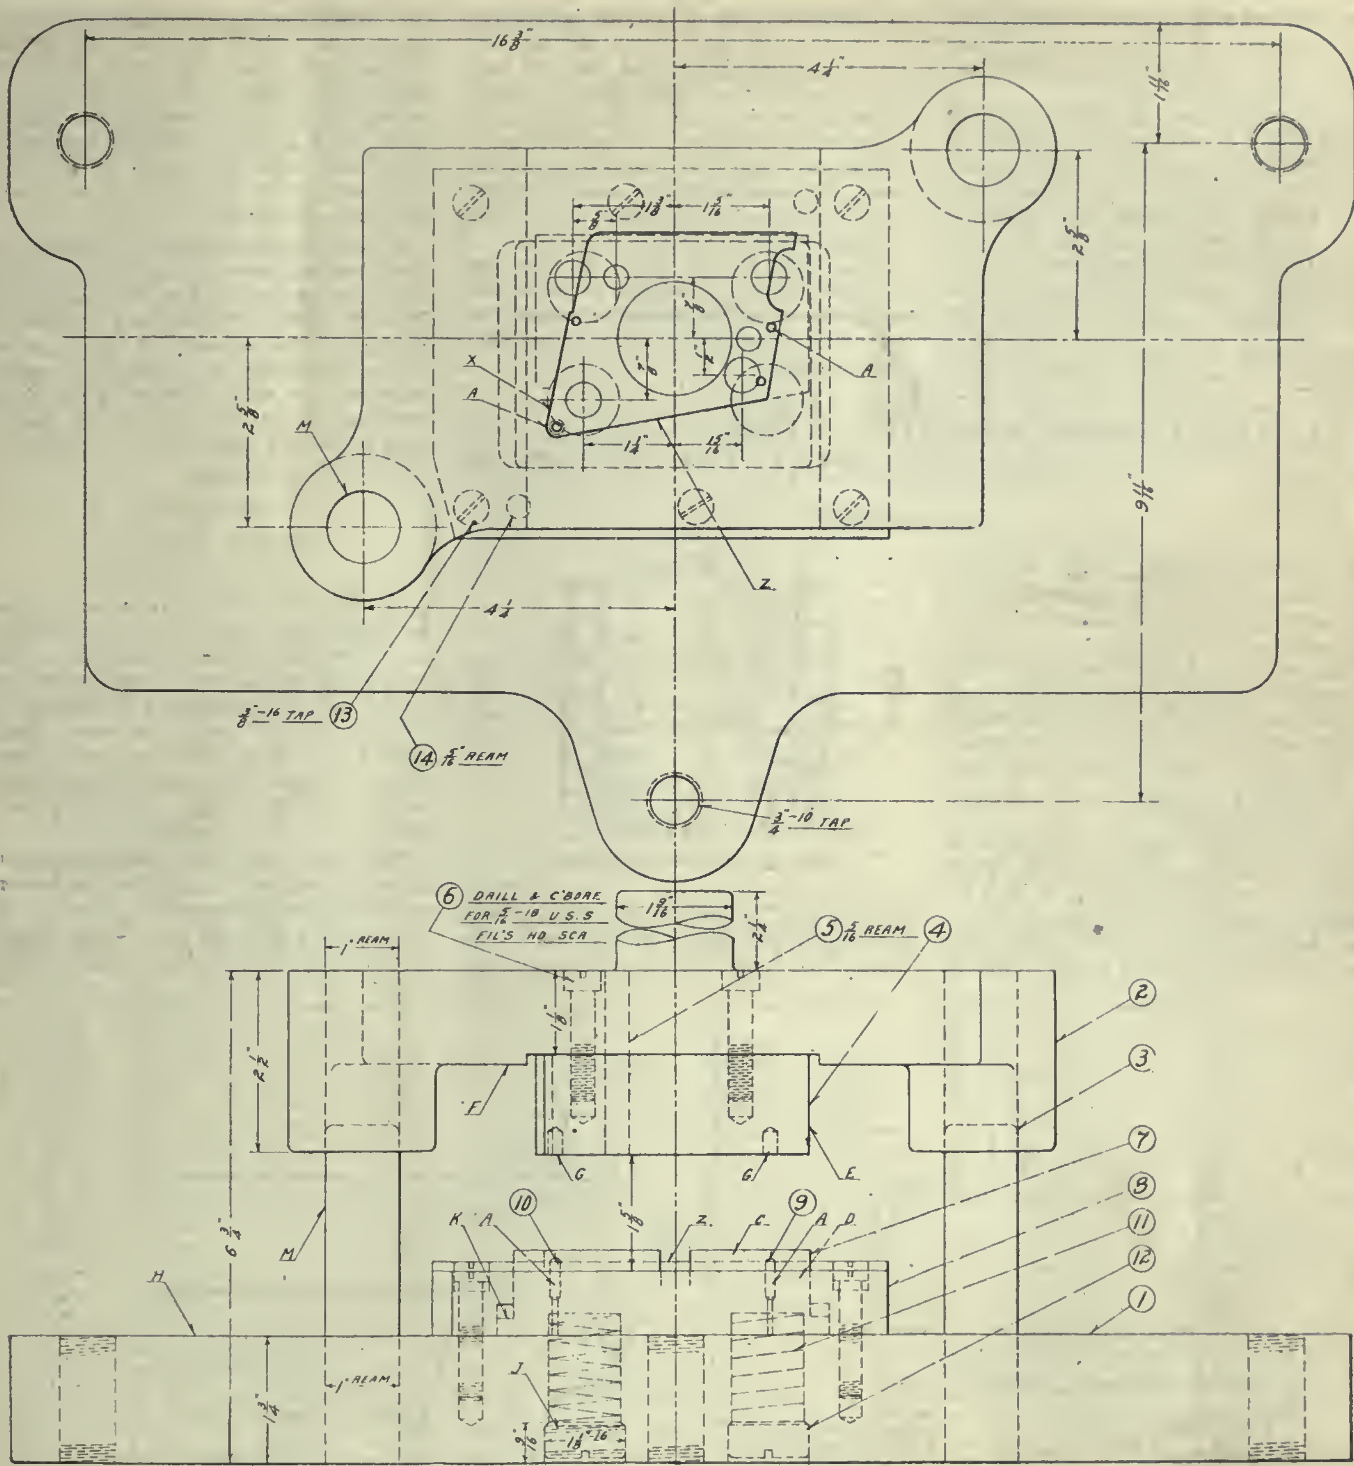

FIG. 1—GENERAL ARRANGEMENT

some of the details of this die each detail shown has a number on it enclosed by a circle and this number corresponds to the same number on the assembly drawing Fig. 1, while in the upper right hand corner of Fig. 2 a list of material is given.

SYMMETRICAL TEMPLETS

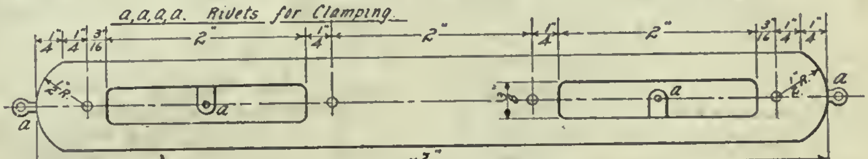
By JOHN ECCLES

The making of a templet, which is symmetrical about a centre line, seems to give many a tool maker considerable difficulty.

From a toolmaker's standpoint the tendency is to work too close to the line before reversing only to find not sufficient stock left to get a clean up.

The trouble usually run into in making only one templet at a time is that errors are never checked as accurately and the finished product does not show the interchangeability it should.

Assuming that we are to make a piece as per illustration, the writer has found the following method most successful. Instead of making one only, choose stock for two and after getting it perfectly flat and doing all lettering, proceed to make the usual lay-out by means of height gauge, (a scale and scratch awl are not accurate enough).



FINISHED TEMPLET

Next, rivet the two pieces together outside of the layout so as not to marr finished piece, placing pins as illustrated to allow for machining.

Machine in shaper or milling machine, leaving about .005 per side outside of line. Next, clamp pieces together and proceed to cut pins off, and after drawfiling spots where rivets have been to limits, start drilling holes in one end only. Make sure the holes are the correct distance from the end and centres.

Now reverse pieces end for end and after aligning sides and ends, use holes drilled as jig for drilling other end.

By means of pin plug in wholes proceed to reverse all ways, filing to the low edge until limit is reached, making sure edges are kept perfectly square. Finish edges to polish.

This will produce a templet that is symmetrical and an extra one is produced for practically the same cost and may be retained as a sample for filling in gauge room.

Some tool makers claim it is easier to make three on account of there not being the same tendency for rocking of file in finishing, and thus a truer edge may be obtained.

A FIXTURE ARRANGEMENT FOR GANG MILLING OPERATIONS

By SCRIBER

AN arrangement for gang milling a number of bearings at one setting is shown by the accompanying illustration Fig. 1.

This consists of a fixture in which is contained suitable locating pins and clamps for holding the work and as the arrangement for holding one piece would be the same no matter how many bearing are held at one setting, but one end of the fixture is shown.

The body of the fixture is indicated as A. and the work is indicated as B. When setting the work in the fixture it is located on three pins at C., D. and E. which three points bearing prevents the work from rocking, it is also located against the two pins F. and G., which therefore must take the thrust of the cut. To clamp the work securely in place the steel plate H. is provided, this has the front edge beveled to hook the corner of the work and the work is forced against this by the hinged clamp J. which is also beveled and pivots on the pin K. in the block L. This clamp is also beveled to hook over the corner of the work and bearings so gripped will be firmly held under heavy cuts.

A nut and ball washer M. complete the work holding arrangement and the fixture may be extended at the end where shown broken off to hold any number of parts up to the capacity of the machine. In the particular instance noted twelve bearings were held, while being machined as indicated by the x marks, a special gang of milling cutters Fig. 2. being provided for this purpose.

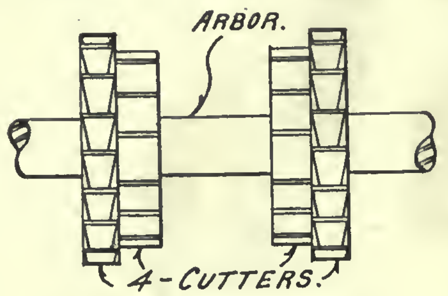


FIG. 2—MILLING CUTTERS

CENTER SQUARE

By C. E. H.

The center square here shown is by no means new, but it is much handier than the commercial article for striking the center on small round work on account of its lightness and balance.

The one I use daily was made from a piece of 1-16 in. tool steel and a couple of screws (see sketch), the heads being cut off after being screwed "home."

The plate was cut to approximate shape, drilled and tapped for the screws and trued up afterwards.

The line A.B. must be at right angles to C.D. and half way between the two

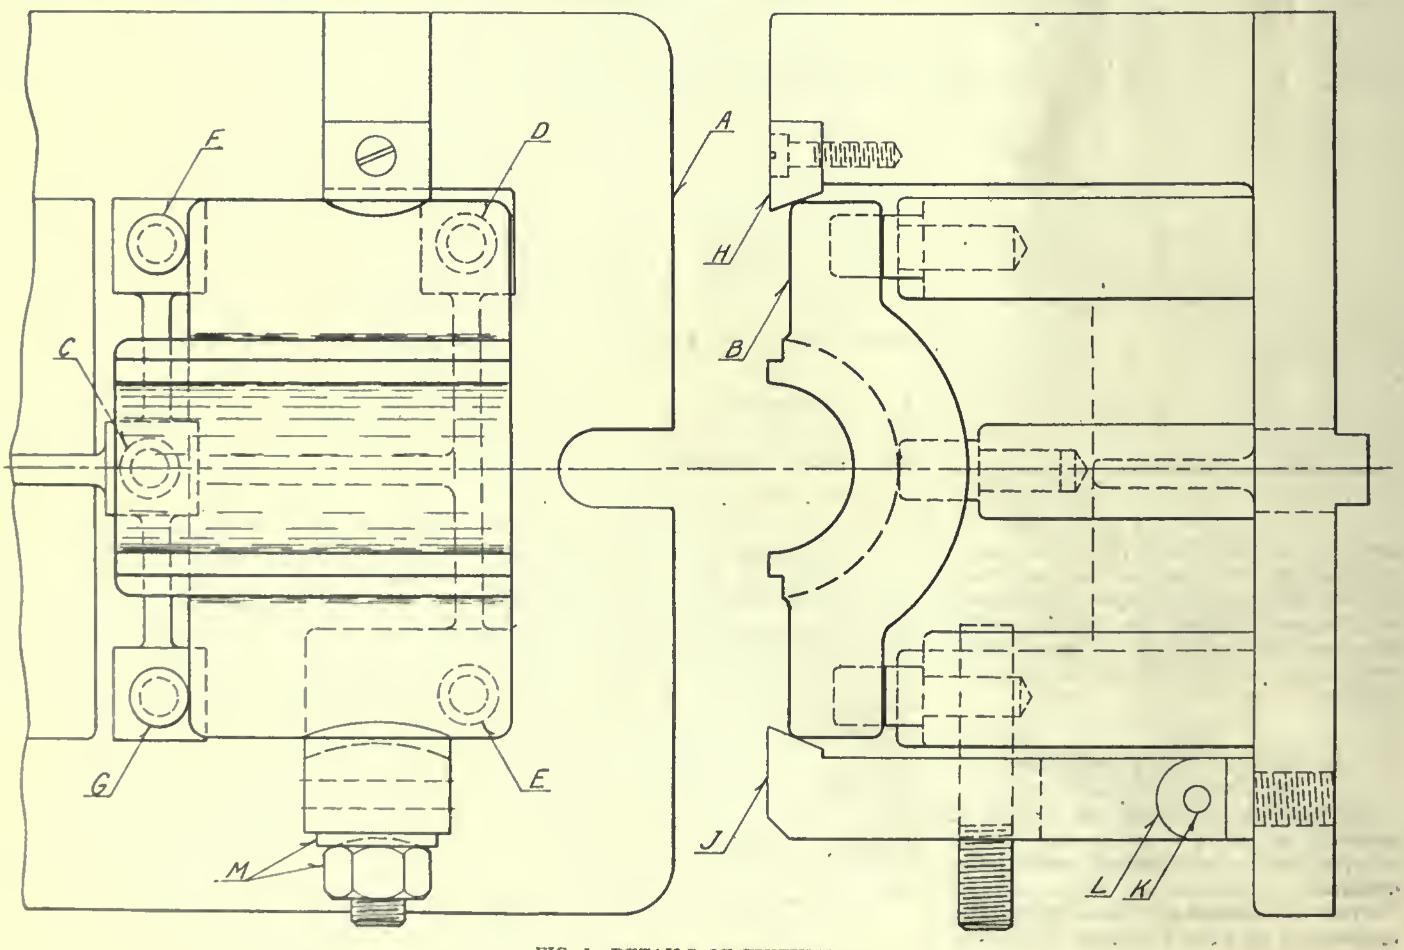

FIG. 1—DETAILS OF FIXTURE

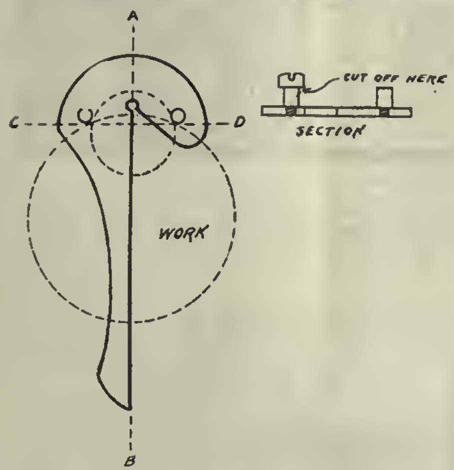
screws, C.D. being tangent to the two screws.

The dotted circles on sketch serve to illustrate its use on round work of different diameters.

By placing the studs against the circumference of the work lines scribed along A.B. always intersect at the exact center.



CENTRE SQUARE

CRITICISM OF EACH OTHER'S WORK IS BOUND TO PRODUCE RESULTS

Dear Sir: In answer to your correspondent A. L. Haas, re line shaft repair. I quite agree with him in the cast of the shafting being of a light nature, and also, the work being the same, the ways and means mentioned would have been all right. As a matter of fact I have run a line shaft break with the aid of two lathe dogs with holes countersunk in the shafting to accommodate the set screws, but be aware it was in the case of a shafting 2½ inches diameter, also with setting shafting collars up tight against the hanger bearings. For a shaft of 6 in. diameter you are not always in a position to pick up a coupling of the above diameter and cutting the keyway would take almost as long as cutting same as I mentioned, and would also have had the trouble of losing about three large pulleys that were dead against the face of the hanger bearings and sliding; in any case one length of the shaft back to put on the coupling. As to solid drawn tubing that is out of the question in this case as I consider I would have a lively time in securing tubing of this size, and I think that it would not stand up to the work it had to do.

The pulley boss would be all right in some cases as I have also used this means of repairing a shaft, not a line shaft but one in a machine.

I must mention that in the case of the pair of collars the break was a direct and nearly even twist break as we found the same had been fractured for some time, as I should say 1-5 of the way through the break it was very rusty, which clearly shows my above statements to be correct.

If I am not mistaken I think the repair took us about nine hours or thereabouts.

I am pleased to know your correspondent took an interest in contradiction as to my method as it shows other ways and means of doing the job, and I have always maintained that if there were more of these good-natured criticisms of one another's work it would be much better for all concerned. Trusting I may have the pleasure of sometime renewing the acquaintance of Mr. A. L. Haas.

A. H. HOULDSWORTH.

INFLUENCE OF WAR CONDITIONS IN THE QUALITY OF GERMAN IRON

In the course of his explanation of the debased quality of German iron castings made under war conditions, Professor Osanne points out, as the cause of the undue hardness, with its bad consequences, a lack of silicon in the metal. Analysis frequently shows a percentage as low as 1.5 and 1.0. Moreover, the produce of one and the same blast-furnace varies in silicon content between 1.5 and 3 per cent. The difficulty is due to the interruptions of the supply of raw material. The requisite proportions are maintained as far as possible by an addition of scrap. But there is necessarily a falling off in silicon with every melting. Besides silicon there is a corresponding diminution of magnesium content To make matters worse, the proportion of sulphur and phosphorus is, from the same causes, no longer under control. The writer, in suggesting remedies, recommends the use of larger quantities of Luxembourg pig iron.—"Giesserei Zeitung."

TO ASCERTAIN THE SPEED AND DIRECTION OF AIRPLANES OVER THE WATER

The practicability of flying over long stretches of water is handicapped by the difficulty of determining the direction and speed of flight. Admiral Fiske proposed a means of overcoming this difficulty based on the idea of making an aeroplane follow the same general procedure as a ship does.

For long flights over water the machine should be made to fly quite close to the water and steer a straight course, not only laterally, but vertically, thus enabling the pilot to obtain information concerning the direction and speed of flight from the water itself by means of what may be called "an airplane log."

The direction can be ascertained by towing through the water a small object by means of a long and light steel wire. The small object will always be in the vertical plane containing the fight path, and the direction may be found by attaching the log line to the end of a pointer moving under the compass, or to a "dumb compass' kept in agreement with the compass.

To find the speed it would be necessary merely to tow a "Massey's log"—a simple contrivance towed by a ship and consisting of a sort of box fitted with a propeller that actuates dials on the surface of the box when it turns. The dials indicate the distance the box has been towed, and knowing the time, the speed can be determined. The error that might be made in calculating the speed is estimated at 2 per cent.—"Aerial Age Weekly."

WELDING CAR AXLES

The price of car axles has increased about 250 per cent. during the past three years, and deliveries are now very uncertain; hence broken axles should be welded whenever possible. By the electric arc method a good man can prepare and weld two 4-inch axles per day; the cost of a finished reclaimed axle is only about one-third that of a new one.

The axle is burned off by the arc to V shape, 5 or 6 inches inside the wheel fit so that only good "live" metal is used in the reclaimed axle. Two prepared pieces are laid in an angle iron with their V-ends together. They are then welded together, using a carbon electrode and cold rolled steel as filler. After the weld is partly completed the axle is rested on a simple trestle and filling-in is completed. The axle is then cut to length and machined. The weld comes nearly in the centre of the completed axle.—R. H. Parsons, "Electric Railway Journal."

HOLLAND'S COAL AND IRON TRADE IN WAR TIME

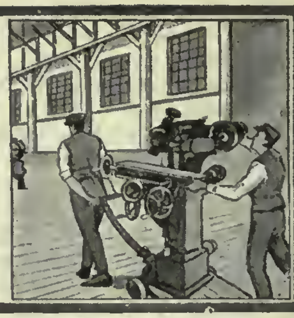
The degree in which Dutch industries have suffered from the war is indicated by the serious contraction of the iron trade in the last three years.

The imports of coal which reached 11¼ million tons in 1914 shrank to a little more than 2½ million tons in 1917. The exports amounted to only 58,000 tons in 1917, against 3,962 millions in 1914. The shrinkage in the iron trade has been no less serious. The imports of iron of all kinds amounted in 1917 to only 134,848 tons, against 647,224 tons in 1915. The exports in the same period fell from 171,990 tons to 7,117 tons. The deliveries of iron from Great Britain in 1916 were only a third of what they were in 1913. Since then a serious falling off has taken place. This shortage is compelling the Dutch to seek their supplies in Germany. —"Zeitschrift fur angewandte Chemie."

COVERING CAST-IRON WITH ALUMINUM

We learn from the "New East" that a process for covering the surface of cast-iron with aluminum has been discovered and tested in practice. The iron is first galvanized or tin coated and then plunged in a bath of molten aluminum at a temperature of 700° to 800° C. While in the bath the surface is rubbed with steel brushes. The tin or the zinc goes over to the molten aluminum and is replaced on the surface of the iron by aluminum. Two or three baths are required, but the larger part of the tin or zinc is displaced by the aluminum in the first bath. The advantages of the process are: remarkable firmness of adhesion, and economy compared with pure aluminum.—"Metall und Erz."

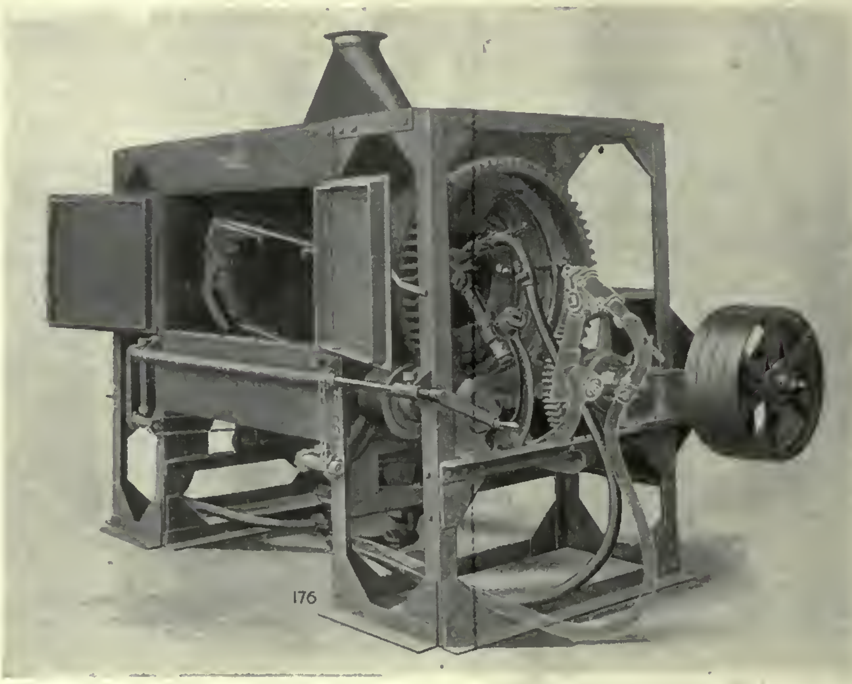
DEVELOPMENTS IN SHOP EQUIPMENT



Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.

HORIZONTAL SAND BLAST MILL

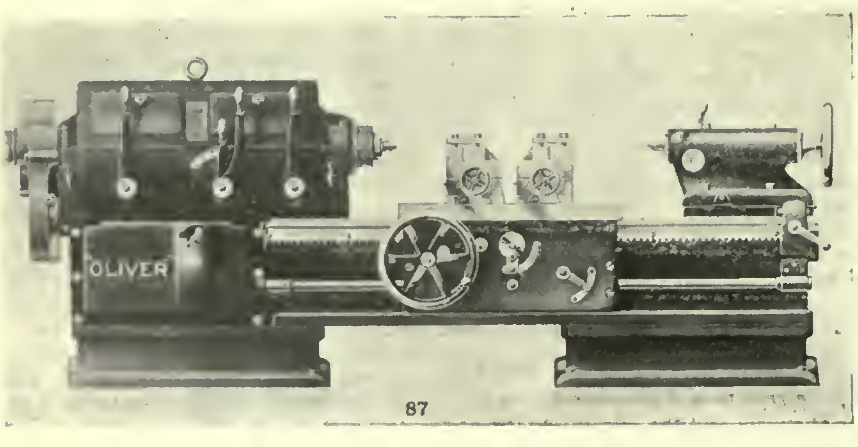
An interesting feature among the exhibits at the Milwaukee Foundrymen's Convention was that of the W. W. Sly Manufacturing Co., Cleveland, O., and which is illustrated below. This machine is known as the No. 30/40 sand blast mill, the barrel being 30 in. by 40 in. There are many new features embodied in the design of this machine, as for instance the motion of the barrel, which is both oscillating and rotating. The bearings are all of the roller type and are located outside of the housing so as to be completely protected from the action of the sand and dust. The sand blast guns are the Booster type, the efficiency of which is well known. The guns are mounted on brackets and can be adjusted to any desired position, and the bracket can also be thrown back as shown in the illustration. A very good feature of the barrel is the arrangement of the door, which is so constructed that it can be neither opened or closed until two levers on either end have been struck sharply. The position of these levers make it compulsory for the operator to have arms and head clear. The barrel door also locks automatically in the open or closed position. The door is made of ¾ inch steel plate and is strong and rigid. Care has been taken in the design to ensure ready access to all parts needing lubrication, inspection, and repairs.



SLY SAND BLAST DRILL

TWENTY-EIGHT INCH SHELL LATHE

The special heavy duty tool shown in the illustration is manufactured by the Oliver Machinery Co., of Grand Rapids, Mich. This machine has all-geared head with single pulley drive, and may be arranged for either motor or belt drive. It is somewhat of a single purpose lathe, the feeds being few and very heavy. The machine, which is of very rugged build, has been designed with the purpose of getting the very best results from high-speed steel. All the gears are of steel, and the pinions made from steel forgings. The spindle is forged from high carbon steel, and accurately ground. The bearings, which are made extra large, are fitted with replaceable bronze bushings, and are made adjustable to take up the wear. The apron is of the double wall type with removable front plate permitting the mechanism to be viewed at any time without the necessity of removing the entire apron. The controls are simple and well arranged.



OLIVER 28" SHELL LATHE

NEW HORIZONTAL BORING MILL

The demand for an ever-increasing supply of large machine tools by the different government departments and private manufacturers has been met by machine tool makers in a very satisfactory manner. A type of machine called for very largely is the horizontal boring mill of the floor type.

In this connection we illustrate this month a mill manufactured by the Giddings & Lewis Mfg. Co., of Fond du Lac, Wis., and described by them as No. 4 floor type boring, drilling and milling machine.

The machine has been designed with a view to adaptability, and the operations that can be performed on it include boring, drilling, milling, tapping, threading, facing, turning and slotting. The accompanying cut shows clearly the general arrangement of the machine. Following are some of the salient points in the makeup of the machine.

Floor Plate on Runway

The large floor plate is firmly bolted and doweled to the runway, both of which are supplied with generous-sized surfaces resting on the foundation. They are cross-ribbed and have metal properly distributed, thus making them strong enough to remain in perfect alignment after being properly installed. The "T" slots of the floor plate are conveniently positioned to receive the anchor bolts securing the work and they are machined out of the solid metal. The floor plate itself is machined all over, affording convenience in gauging and aligning the work.

The Column

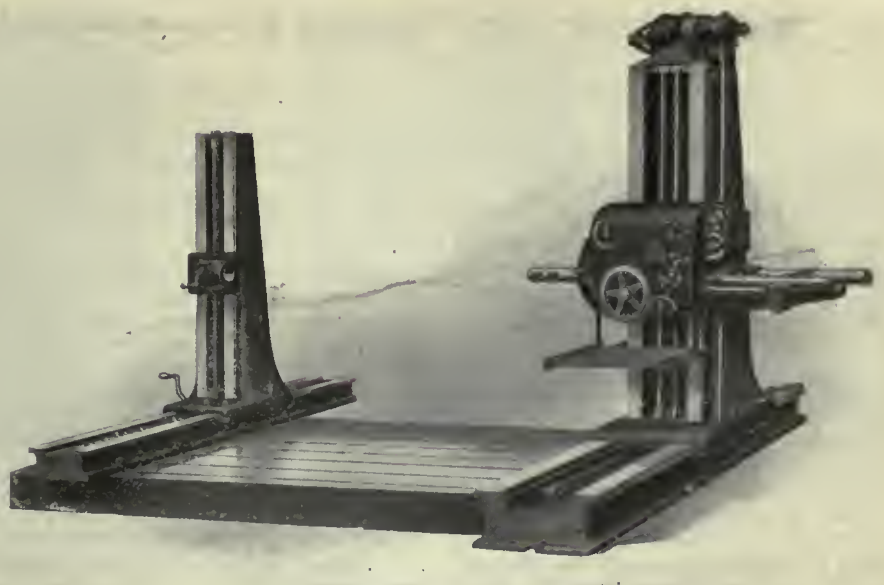
Great care has been taken to furnish the necessary strength for this important part. It is well ribbed, and has metal correctly distributed to withstand all unusual strains to which it is subjected. The base or bottom surface is supplied with an unusual spread in all directions where it rides the generous-sized ways of the bed. Lost motion between these parts is eliminated by means of long taper and square-locked gibs.

The End Support

While not subjected to the major strains such as the column, this part is made unusually strong in order to perform its functions when used as the outer support for long boring bars, etc. When necessary to use, and it is possible, this end support should be placed as close to the work as convenient. This is accomplished by sliding the piece over the top of the floor plate, it being guided by a long key. It is entirely independent from the rest of the machine and can be easily removed when it is desired to place extra large work on the floor plate. All of the adjustments on this unit are made by hand in the most convenient and accurate manner possible.

The Headstock

The headstock is of boxed design and unusual strength, furnishing perfect support to all of the moving parts. It has very large vertical and horizontal dimensions on the face of the column. Rigidity is obtained by means of two taper square-locked gibs. The face or outside surface is supplied with a cover which is removed to adjust the spindle sleeve bearing and other inside adjustments. Located on the top and within reach of the operator are oil reservoirs which supply lubrication for all of the bearings. From the bottom of this unit is suspended the operator's platform, which is designed to ride with the headstock at any position. When the headstock is at its lowest extreme the platform supports telescope and allow it to ride the ways of the bed. This platform places the operator directly before and convenient to all controlling mechanism and makes it possible to actively control the machine at all times, thus keeping it continually in the cut and making maximum efficiency possible.



NEW HORIZONTAL BORING MILL

The Spindle and Sleeve

The centre of the heat-treated, hammered high carbon steel spindle is positioned unusually close to the face of the column, eliminating an undesirable overhang. It is ground to exact size and the front end is bored to receive the Morse taper shank, tang, and drift key, while the back end is equipped with a ball thrust bearing, through which the feed is transmitted by the use of an extra long ram, carrying the rack, which disengages with the pinion at both extremes. The power is transmitted to the spindle from the sleeve by means of two long spindled keys, diametrically oppo- up collet is provided and by its proper adjustment the slide of the spindle is made snug, thereby allowing for precision alignment. The sleeve, like the spindle, is made of heat-treated, hammered, high carbon steel, and is of unusual length and strength. It is rigidly supported in two generous-sized adjustable bronze bearings placed far apart. Each of these bearings is independently adjusted for taking up wear, thus eliminating all lost motion. The front face of this sleeve is prepared to receive milling cutters and attachments.

To the spindle sleeve are secured two large driving bull gears. The front or face gear, being the larger, receives its power through the sliding back gear shaft. The power is transmitted through the variable speed unit located at the upper right-hand corner of the headstock. This selective gear speed unit contains heat-treated steel clash gears, cut with stub teeth to provide additional strength and ease of operation. The high speed shafts in this unit are ball seated and all heavy-duty shafts have generous-sized phosphor bronze bearings.

BONUS SYSTEM FOR ECONOMY OF COAL IN GENERATING STATIONS

It is argued that it is desirable to encourage economy in the coal consumption in generating stations by interesting the employees in the saving by a bonus system, according to which the money saved is equally divided between the employees and the undertaking. The division commences as soon as the consumption of coal falls below a certain limit. This limit is set according to a calculated consumption based on the efficiency to be expected from the plant if run with care. In a calculation concerning a special installation with a peak load of 25,000 k.w. and a wage bill of Fr. 700 a day, the consumption limit from which the bonus should commence is found to be 6,400 calories per k.w. hour.—L. Conge, "Revue, General de l'Electricite."

LIFTING HEAVY PARTS FOR MACHINING

By D. S.

In a great many instances where heavy stuff has to be fixed in machines too much reliance is placed on manual labor, both strength and time being rather uselessly wasted in this kind of work. If a piece of metal or other material can be mechanically lifted and slung into position, say over a lathe there only remains the adjustment of position to be dealt with, and this is easier to manage with a slung article than with one supported by men's arms, let the men be as experienced and careful as they may. The methods of slinging will probably depend on the conveniences possessed by the machine shop, and will vary between overhead runways which will serve a long line of machines, to small portable cranes which move about on wheels, the matter being one of both cost and convenience. Whatever is used, however, it should be capable of holding the slung article in a convenient position for fixing, and in addition to the lift from the trolley or other carriage on which the article is brought up, should be clear of the machine itself, for very obvious reasons. A large saving can be made by using appliances of the kind with reduction of cost.

Modern 150 Ton Track Scale Now in Use

No Knife Edges Employed, but Plate Steel Fulcrums Used Instead —Assembled by Locomotive Crane—Scale Pit is Heated by Hot Water System—Great Advances Made in This Work

By FRANK C. PERKINS

THE accompanying illustrations, Figs. 1, 2, 3 and 4, show the details of construction of the standard railroad track scale, developed at Pittsburgh, Pa. These photographs of this modern 150-ton railroad track scale show the mechanism at close range, with six of the eight central transverse levers connected with the longitudinal levers plainly visible. The bearing on high stands will be noted supported on concrete piers. The opening in transverse levers provides access to alignment of girders on lever system by adjustment of nuts under girder.

The weigh beam house of this 15-ton railroad track scale has convenient windows for observing movement of cars. The uncovered scale shows the deck beams supporting the dead rails; also shorter steel ties supporting the live rails. By varying thickness of rail bases on top of beams all four rails are on the same level.

It is pointed out that the building of modern scales by the aid of a powerful crane reduces the cost of erection and the men work under safer conditions. The illustration Fig. 4 shows the placing of steel ties for weigh rails upon the powerful girders, freely suspended upon the lever system, prior to the setting of the longer deck beams.

The Pennsylvania Railroad Company installed the first two section plate fulcrum track scale. This construction marks great advance in the development of weighing machines for heavy service conditions. It eliminates entirely the need for regrinding or renewing knife edges and bearings, which has been a source of heavy expense and annoyance at busy weighing points. It also eliminates the dead rails with their attendant switches and signals. Relieving gear, which has heretofore been used as a substitute for dead rails, is also rendered unnecessary by the plate fulcrum construction and a permanent installation is obtained which will effectively withstand the heaviest service conditions and give accurate weights for fifty years, without any necessity for renewal of parts.

The plate fulcrum track scale has plate fulcrums which are substituted for the regular knife edges and bearings which heretofore have always been used in track scale construction. The plate fulcrums are formed with a relatively thin central portion, connecting two heavier portions or heads. The thin portion forms the plate and gives the desired flexibilty, while the large heads distribute the load on the supporting members and decrease its intensity and, in addition, furnish a ready means for attachment to the levers and the supporting stands. The thin central portions are all arranged so as to act in direct compression and are subjected to a slight flexure as the weighing beam vibrates and the lever system responds to the condition of balance.

The plate fulcrums used as the load plates in the main levers as noted in drawing Fig. 5. This plate fulcrum is a piece of rectangular steel reduced to a thin web section in the centre, thus forming a thin plate of steel which acts in compression under the load imposed on the weighing rails. With this construction the possibility of wear is entirely eliminated in the vital parts of the scale. Wth the knife-edge construction, when the scale is new there is practically a line contact between the knife edges and the bearing steels, but in the course of time the bearing surfaces increase and the knife edges are said to be dull or blunt. When this condition exists, inaccuracies are introduced into the weights and it is necessary to repair or renew the pivots and bearings if accurate weights are to be obtained. With the plate fulcrum construction, any possibility of such wear, with subsequent inaccuracies, is entirely eliminated, as the thin plates of steel remain in their original condition regardless of the amount of weighing that is done on the scale.

The scale is installed in a concrete pit as the foundation piers and walls are heavily reinforced with twisted bars. The inside length of pit is 69 ft. and its inside width measures 10 ft., the height from top of foundation piers to base of rail being 10 ft. 6 in. and the distance from centre line of scale to centre line of weighing beam is 10 ft. for an effective weighing rail of 52 ft. The additional length of pit is used to provide approach spans supporting a short section of rail which is independent from both the main track and the weighing rail.

The weighing rail is supported on cast iron rail stands, which in turn rest upon steel cross ties supported on the main girders. The rigid deck type of construction is used and the deck is composed of 5-16 in. steel plates supported on 12 channels which rest on bearing plates supported by a ledge in the side walls of the pit. These channels are curved so as to give a crowning effect to the deck, which will effectively shed surface water. The steel plate is covered with ¾ in. cork brick.

The scale assembled before being installed may be noted in Fig. 6, while

FIG. 1 WEIGH BEAM OF 150 TON TRACK SCALE

FIG. 3—CENTRAL TRANSVERSE LEVERS OF 150 TON

FIG. 4—150 TON TRACK SCALE

Fig. 7 shows the main and longitudinal extension levers. In the photographs Figs. 8 and 9 may be seen the beam poise and the weigh beam of this plate fulcrum track scale. This scale is of the two-section type wherein four main levers transmit the load to two longitudinal extension levers which in turn transmit to a transverse extension lever and this lever is connected directly to the weighing beam. The main and longi-

FIG. 5—DETAIL OF TYPICAL PLATE FULCRUM

tudinal extension lever stands are directly supported on massive base castings which rest directly on the concrete foundation. Only seven levers are used in the scale, thus making a remarkably simple and effective construction and eliminating entirely the complication of intermediate sections which is encountered when the four-section type of scale is used. The main girders are so designed that a test car may be placed directly over the center line of a section.

It is claimed that this has never been practical wtih track scales built in more than two sections. An effective means is thus provided for accurate calibration, and as there are only two sections in the scale the final adjustment in the field is extremely simple. The main bridge is constructed of two plate girders, one on each side of the scale. They are 5 ft. 2 in. deep, back to back of angles, and reduced to 2 ft. 7 in. back to back of angles, where they are supported on the scale sections. Three top and bottom flange plates are used, 17 in. x 9-16 in. The flange angles are 6 in. x 6 in. x 9-16 in., and the web plates are ½ in. The girders are securely tied together by means of transverse and diagonal bracing so that a very rigid brindge construction, which will effectively resist longitudinal and lateral strains, is produced.

The steel cross ties are composed of 10 in 35 lb I beams, and these are securely riveted to the top flange of the girders. The railstands are supported directly on the cross ties. The approach spans are composed of 18 in. 70 lb. I beams, which are supported on base plates provided with spool bearing which provide a means for the alignment of the approach rails with the weighing rail without any distortion or springing of the rails. The 18 in. I beams in turn support a steel casting which furnishes a support for an intermediate rail stand under the approach rails. These rails are 6 ft. 8 in. long and are independent both of the weighing rail and the rails in the main track.

The rail stands are designed to shed the surface water. This is accomplished by two umbrella flanges, one above the deck and the other below. The top flange will shed the most of the surface water away from the opening in the steel deck. The lower flange in turn sheds the small amount of water which may pass through into a water trough under the deck and a system of spouting is arranged to convey the water to a pump in the bottom of the pit.

The lever system consists of four main levers made of steel castings and each lever is arranged to support three plate fulcrums. For the reception of the load plate, a rectangular recess is provided of sufficient width to accommodate both the head of the plate fulcrum and a clamping block. One side of the head is vertical and engages with the vertical side of the recess. The other side is tapered and engages with a corresponding taper on one edge of the clamping block. The opposite edge of the clamping block is vertical and engages with the vertical edge of the recess opposite to the plate fulcrum when in position. The clamping block is arranged so that its lower surface does not engage with the bottom of the slot in its final position and it is forced down into position by means of cap screws. This action forces the plate fulcrum head firmly against the side of the recess and retains it in a fixed position. The butt and tip ends of the levers are provided with square seats, which form supports for the end plates.

The end plate fulcrums are drilled through the heads and securely attached to the levers to cap screws. The design is so arranged that the load is trans-

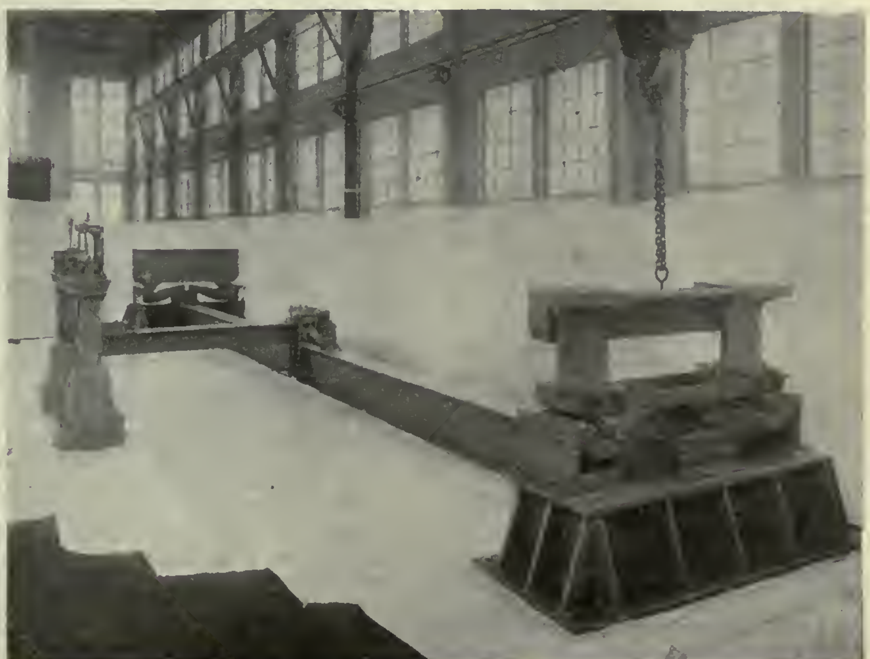

FIG. 6—THE SCALE ASSEMBLED BEFORE OPERATION

ferred directly to the solid portion of the lever and the cap screws are relieved of all shearing strains. The seats for the plate fulcrums are very accurately machined so as to maintain the true theoretical distance between the centre lines of the plates and also to preserve their exact parallelism. The longitudinal extension levers are composed of 20 in. 140 lb. Bethlehem girder beams to which are attached at the butt ends heavy steel castings for carrying the plate fulcrums.

Heavy steel castings forming angle plates are provided at each side of the web and these plates are held in position by means of tapered bolts accurately fitted into reamed, tapered holes. The casting carrying the plate fulcrums is in

FIG. 7—MAIN AND LONGITUDINAL EXTENSION MEMBERS

turn secured to the reinforcing angles and flanges of the I beam by tapered bolts which are made a driving fit into reamed, tapered holes. The plate fulcrums are supported in square, truly machined seats and are held in position in the same way as the end plates in the main levers. Bearing plates are applied to the tip ends of the levers and are held in position by means of bolts and dowel pins. These plates are provided with longitudinal recesses which form sliding ways for the nose irons.

The nose irons are steel castings provided with truly machined seats for the heads of the plate fulcrums, which are used at the end. They are held in position on the levers by 1¼ in. studs. Adjustment of the nose irons is furnished by means of non-corrosive adjusting screws. The transverse extension lever is composed of a 10 in. 105.5 lb. Bethlehem H beam and is furnished at the butt end with a heavy steel casting for the support of the plate fulcrums. This casting is secured to the I beam by means of tapered bolts, accurately fitted into reamed, tapered holes. The nose iron is of cast iron and the plate fulcrum is held in position in the same way as in the nose irons for the longitudinal extension levers. It is held in position by 1 in. studs and adjustment is provided by means of a non-corrosive adjusting screw.

The multiplication of the levers is as follows:

	Multiple
Main levers	3½
Longitudinal extension levers	20
Transverse extension lever	11 3-7
Butt of weighing beam	800

The lever stands are steel castings designed with a single web section connected to a heavy lower flange. They are accurately machined for the support of the plate fulcrums, the seats being made in the same way as the end seats in the main levers. In the plate fulcrum construction it is necessary that one of the plate fulcrum heads be attached to the lever and the other to the lever stand or to the block transmitting the load so that it is necessary to provide accurately machined seats both in the levers themselves and in the lever stands and bearing blocks. The lever stands for the main and longitudinal extension levers are directly supported on two main base plates, one at each end of the scale.

Each base plate provides support for two main lever stands and one longitudinal extension lever stand. The stands are bolted to the main base plates with 1 in. bolts, and after their proper location has been determined so that both the main levers and the longitudinal extension levers can be assembled and connected without introducing any initial strain in the plate fulcrums, the stands are permanently maintained in a true and accurate position by two ⅞ in. dowel pins passing through the lower flange of each lever stand and the upper flange of the main base plates. The main base plates are 24 in. deep and are heavily ribbed so as to effectively transmit and distribute the load over the concrete foundation.

The transverse extension lever stand is supported on an independent base casting of ample proportions to distribute the load evenly over the foundation. The base plates are accurately machined on both the top and bottom surfaces so as to provide a true seat on the top surface for the lever stands and to provide a true and even surface to rest on the concrete. The piers supporting the base plates were hammer dressed and rubbed down so as to have them true and level, as it is very essential that the base plates should be maintained in a truly level position, and in order to overcome any slight inequalities that may have been left in the concrete foundation a ¼ in. thickness of "linotype" was used between the concrete foundation and the base plates. One and one-eighth inch "cinch" expansion bolts are used for holding the base plates in position.

The longitudinal extension levers are connected to the transverse extension lever by means of radial struts which are furnished with hardened curved steel surfaces in the lower portion which engage with hardened steel-bearing plates supported on a platen, which in turn is suspended by substantial rods from the bearing block engaging with the load plate in the transverse extension lever. The bearing plates are encased by housings which are designed so that they can be adjusted in the longitudinal direction and they are operated by means of non-corrosive adjusting screws. This is necessary so as to enable the radial struts to be maintained in a vertical position, should there be any adjustment of the longitudinal extension lever nose irons. The transverse extension lever is connected to the butt of the weighing beam by means of two suspension rods supporting a platen which in turn supports a radial strut connection directly attached to the end plate fulcrum. In order to prevent any possibility of displacement at theh ends of the longitudinal extension levers a transverse stay plate is provided. This plate is attached at one end to the lower platen and at the other end it is anchored to the base of the transverse extension lever base plate. A stay plate is also provided at theh tip of the transverse extension lever. In this way the true position of all the extension levers is very accurately maintained.

As to the bridge supports it may be mentioned that heavy steel castings provided with accurately machined slots for the reception of the intermediate or load plate fulcrums in the main lever furnish a means for the transmission of the load to the lever system. The slots in these castings are tied together in the trans-heads of the plate fulcrums in the main levers are a "sucking" fit therein. The castings are tide together in the transverse direction by means of tie bars, and after they have been accurately spaced so as to maintain the plate fulcrums in a truly vertical position they are held in position by means of ⅞ in. dowel pins. The main bridge is fixed at one end and free to move at the other. The fixed end is supported by means of a transverse I beam engaging directly with the bearing castings above referred to.

It will be seen that the movable end of the bridge is supported on cast steel struts provided with hardened steel inserts, ground to a radius, and engaging with hardened steel plates at their top and bottom surfaces. The lower plates are directly supported on two steel castings similar to those described for the transmission of the load at the fixed end. The housings are provided for the steel

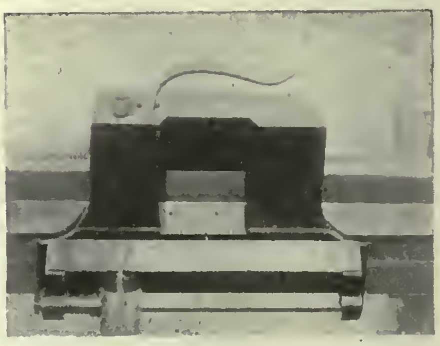

FIG. 8—BEAM POISE

bearing plates and adjustment is provided in the longitudinal direction by a non-corrosive adjusting screw so that the struts may be placed in a truly vertical position when the bridge is in its normal longitudinal position.

There is a heavy casting directly connected at the movable end to the main girders by means of 1 in. bolts and a layer of stereotype metal is used between this casting and the lower flange of the main girders. The top bearing plates engage with this casting and are secured in position, as adjustment is not necessary at the top of the struts. Recesses are provided at the top and bottom bearing plates in which oiled felt is inserted so as to prevent rusting of the rocker or the housing. This felt is in turn protected by means of shields, which are secured to the struts by means of cap screws.

The main bridge is checked in the longitudinal direction by means of a stay plate 44 in. wide by 1 in. thick, reduced to ¼ in. at each end so as to allow for flexure. This stay plate is secured to the girders by means of a heavy transverse connection and is anchored to a cast steel transverse support which in turn is securely anchored to the foundation. The transverse checking is arranged with a substantial connection to the transverse support at the movable end of the bridge and is connected to a rigid support attached to the side walls of the pit. These transverse checks are composed of two rods 2⅛ in. in diameter and reduced to 1½ in. in diameter at each end to provide for flexure.

The weighing beam noted in Fig. 9 is of open hearth steel machined all over. It is notched, fitted and sealed with the utmost care and is supported by means of plate fulcrums of the proper dimensions to give the requisite strength and the necessary flexibility to insure a sensitive scale. It is provided with an indicator which moves over a graduated scale and thus furnishes a means for taking a very exact balance.

There is a locking device provided so that the beam can be securely locked when the scale is not in operation. This device consists of an eccentric which engages with a flat spring so that a pressure of 15 lbs. is applied at the permanent beam stop. A stabilizing weight is located exactly over the fulcrum and is provided with vertical adjustment so that the period of vibration of the beam can be changed at will so as to suit local weighing conditions. Immediately over the indicator fulcrum a small vertical weight is applied, which is provided with screw adjustment in the vertical plane. This has the effect of changing the sensibility of the scale, which can be adjusted to suit local conditions.

There is an oil dash pot provided at the tip end of the beam so as to steady its motion. The beam is graduated for the main beam 300,000 lb. by 1,000 lb. notches and the fractional bar 1,000 lbs. by 50 lbs. An auxiliary weight of 100,000 lbs. capacity is furnished so that it can be applied at the tip of the beam to give a total weighing capacity of 400,000 lbs.

The balance of the beam is obtained by means of two sets of balance weights, one being arranged at the back of the beam for rough adjustment, the final adjustment being obtained by means of a balance weight provided at the butt end and held in position by means of a knurled lock nut.

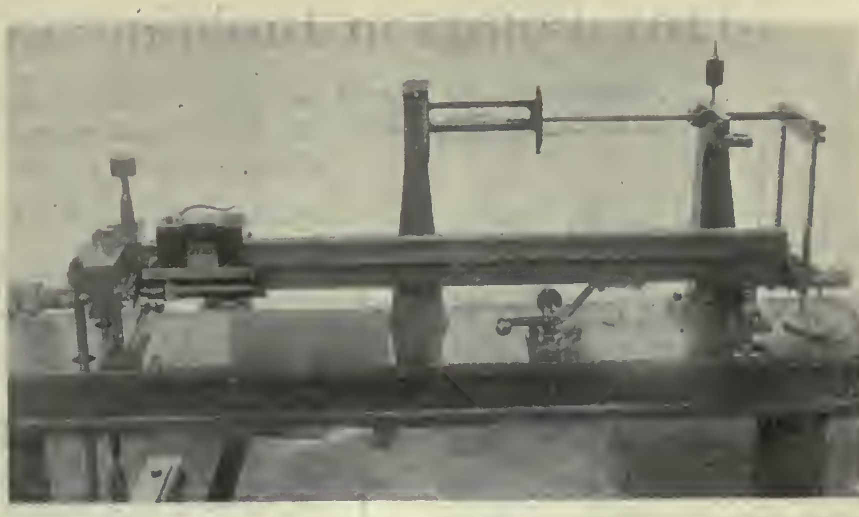

FIG. 9—WEIGH BEAM

The poise is noted in photograph Fig. 8 and is fitted with ball bearings and centre indication is provided for the faces of the main beam and the fractional bar are made of "Monel" metal and the figures and graduations are filled with red. The beam is supported on a well-proportioned metal sheif which in turn is supported on two metal pillars resting on sub-bases which are provided with means for transverse adjustment of the beam outfit so that if it is necessary to move the nose iron in the transverse extension lever a means is provided for preserving the true vertical position of the beam rods.

It is of interest to note that the plate fulcrums in the main and extension levers are composed of high grade chrome vanadium alloy steel with a tensile strength of 200,000 lbs. per square inch. They are truly machined to dimensions and are accurately fitted in the levers. The plate fulcrums in the weighing beam are made of high grade "blue strip" steel. All the plate fulcrums are so designed that when the slight flexure occurs the stresses induced are well within the elastic limit, so that no permanent distortion can occur.

It may be mentioned that the scale pit is heated by means of an efficient hot water system, sufficient radiation being provided to maintain a temperature of 60° in the pit. A number of electric lights are installed so as to properly illuminate the pit so that proper inspection can be made of all parts of the mechanism. The beam outfit is installed in a scale house furnished with a large bay window which gives the weighmaster an efficient view of the scale rail. The height of the indicator from the floor has also been very carefully considered so as to place it in the most desirable location for the weighmaster so as to facilitate the quick balancing of the scale when cars are being weighed in motion.

LINING ROUGH EMERGENCY CRUCIBLE FURNACES

By M. M.

Given an old sheet iron oil or paint drum, about 20-inch. diameter by 30-inch. deep some means of producing blast, if only from a portable forge, a 30-lb. or 40-lb. crucible, and some coke of anthracite, if you line the drum with some fairly refractory material, you can melt anything up to copper. Sandy brick earth, clay, sandy silt from the riverside, scraping off a stoned road—not limestone — and other earths will answer fairly well for a few melts, if dried before firing takes place, and make passably good makeshifts for good linings, but of course, a fire-clay that will burn hard or a good ganister is best, owing to its greater durability. With a little ingenuity, however, emergency melting can be done readily if a little thought is given to the matter.

WATERPOWER

By T. H.

The new Galloway Engineering Works, erected in the south of Scotland, mostly in reinforced concrete, is fitted with a hydro-electric equipment. A dam in mass concrete, 6-feet clear above ordinary water line, battened on to upstream side, strengthened by buttresses, has been built half across the river; from the pool to the headrace a channel, 214-feet long, 13-feet broad and 7-feet 6-inch. deep has been erected in reinforced concrete, Kahn rib bars being used. A good head of water is obtained throughout the year, without interfering with the salmon fishing on the river in any way. The works are approached across the headrace by a reinforced concrete bridge of 15-feet span and 9-feet wide between the parapets, which are panelled capped, by an overhanging coping. These parapets form the main beams, which cross beams at 5-feet centres, supporting 6-inch. reinforced concrete slabs, the whole being designed to carry a 5-ton wagon.

Many Points in Building an Export Trade

Apparently the World is Full of Markets, but the Great Task is to Get Into Them—France Wants to Secure Canadian Goods For Reconstruction Period

EXPORT trade, both for itself and in relation to demobilization and reconstruction, is a practical proplem to be faced immediately. The presence, in the deputation that interviewed the Cabinet in Ottawa, of James T. Gunn, vice-president of the Labor Party of Greater Toronto, indicates that the matter is not wholly for the employers to decide, but that the workers also must have their voice.

It is estimated that, with the coming of peace, between 600,000 and 700,000 Canadian men and women would be released from military service or from purely war industries. With their families, a million and a half or perhaps two million people will be affected in the readjustment period.

Various plans to provide employment are already under consideration, including land settlement and large public works, but industrialism must do its share. The home market in itself must be developed, but that alone is not sufficient. A greatly increased export trade must be sought.

Europe and Russia

What is the market for such a trade? For one thing, there is the physical reconstruction of the devastated areas. In 1917, the loss of industrial, agricultural and public property in France, Belgium, and the eastern theatre of war alone was estimated at $6,000,000,000. Since then, other billions have been added to this total. There will be a demand for lumber, furniture, railway equipment, building supplies and agricultural, mining and electrical machinery. There is also the field of **Russia**. The Government has appointed a commercial commission to study the possibilities there. Binders and tractors will be needed, and all sorts of farm machinery, including equipment for the flour milling industry.

There is no lack of markets. How can Canada get her share of the business? In export trade, volume is essential, and in this country there are probably not very many industries which have sufficient resources to enable them to penetrate by themselves into forign markets.

It is advocated in some quarters therefore, by Hon. Frederick Nichols for example, and by the Canadian Industrial Reconstruction Association, that there should be a combination or federation of kindred industries, with common shipping anl common selling agencies.

It is true that in Great Britain and in the United States, such federations for after-war trade are being formed. The British Trade Corporation, with a capital of $500,000,000, has been organized to ensure credits, give financial backing to British enterprises througout the world, and to furnish information as to opportunities for trade extension in foreign countries. Among other bodies is the Federation of British Industries, which is spending $12,500,000 to stimulate exports.

In the United States similar tendencies are at work. The Webb law reverses previous American policy and permits combinations of producers and manufacturers for export business. A federation of industries, including 300,000 plants and 10,000,000 workers, is being organized.

Such developments are not without their serious potential dangers. Combines in the past have not been popular, nor have their results been beneficent. If, to face new conditions, combinations or federations (which would probably be looser ehan the old combines) should spring into existence here, their activities would have to be carefully scrutinized and a constant watch kept over their tendencies.

Here is where labor figures. Such federations of industries, if they are to exist at all, should be humanized by the direct participation of labor in their management. Democratic control of industry is a slogan which is sure to grow

---

VETERAN MANUFACTURER'S VIEWS ON THE CLOSE OF THE WAR

By JOHN McCLARY, President, McClary Mfg. Co.

I predict that at the close of the war there will be such a rejoicing that for a time the disturbed future will be overlooked. The war has created a condition that will require the united wisdom of our ablest statesmen to meet, and do justice as far as possible to our returned soldiers, to labor, and to the general public.

Bonar Law, many months since, issued a statement to the British public that, after the return of their triumphant soldiers, it would be as great, or nearly as great, a task to absorb them as it was in the first place to create them. They would have to be kept employed and well paid if they did not earn half their salaries —intimating the necessity of producing merchandise beyond the requirements of the limited, disturbed, world's market, and citing pig iron as an illustration which would not depreciate in carrying. These conditions apparently could only be carried through by the action of the Government. These views reflect to some extent, what we may look forward to at the close of the war.

The first effect on our cities will be the stoppage of production of war materials. These highly paid artisans engaged in this work would be thrown idle. The inflated prices of merchandise, running from one to three hundred per cent., must suffer a gradual sinking back to more normal levels. The raw materials of the McClary Manufacturing Company average, upon the whole, fully three times normal prices of metals and other products consumed.

The first effect of the closing of the war will be to create a waiting condition. Outside of food, the average consumer will purchase only for immediate requirements. The manufacturer, in most lines, will only produce reduced outputs to even up his stock, looking forward to his raw materials gradually shrinking back to the former normal prices. While he has a duty to perform to employees as far as conditions reasonably permit, there is likely to be a largely reduced number of operatives, with a corresponding reduction in salaries, having an unfavorable influence on trade in our cities. Many trades now doing apparently a prosperous business will find their sales reduced, and their stocks carried depreciating from month to month, causing, I fear, many failures, especially among traders who have kept their stocks up to normal, assuming the present inflated prices would continue.

The depressed conditions will continue more or less for a period, I assume, of twelve months or more.

The farmer will continue to be comparatively prosperous, the purchaser of merchandise for immediate requirements.

in strength both in England and America in post bellum days. If the workers did have a greater share in the management and operation of industrial establishments, if they were given more responsibility for production, like the coal miners in Pennsylvania, and, at the same time, more privileges and rewards to match the responsibility, then neither single industries nor groups of them would be sources of dissension or rancor.

FRANCE WANTS CANADA'S HELP FOR PERIOD OF RECONSTRUCTION

WITH Canada aproaching the period of reconstruction when war industries must be readapted to peace activities and new trade secured, it is encouraging to note the possibilities of greatly improved commercial relations with France. At the recent meeting of the Canadian Reconstruction Association at Montreal, Senator Beaubien emphasized the desire of the Republic for increased trade with the Dominion. "Deeply moved by Canada's effective co-operation in the war," he said, "France seems anxious to show her appreciation of our efforts. Inspired by that desire, the Comite Franco-Amerique, which is presided over by Monsieur Gabriel Hanotaux, and whose principal object is to extend to the fields of industry the close relations now welding Canada and France on the fields of battle, has called the attention of its Canadian section to the great trade opportunity afforded in reconstruction work necessary to restore the devastated areas of France. It points out that many nations are already eagerly seizing this opportunity and strongly urges Canada to do likewise. The Canadian section of the Comite Franco-Amerique has already recommended to the Government that an Honorary Commission, assisted by experts if necessary, be appointed to ascertain what Canadian products could be furnished for the work of reconstruction in France, pareicularly such products as can be standardized and provided in large quantities. The Canadian Association further suggested that this Commission should negotiate with the French Government "with a view of having France, as a nation, purchase large quantities of such standardized products with the understanding that the orders for such materials would be handled by Canada in the same manner and through the same channels as war orders."

In supporting measures for greater trade with France, Senator Beaubien submitted some striking figures of our present exportation to prove that large orders can be secured from the Republic. Within the last two years orders have been placed in Canada for very large amounts of metallurgical products. One enquiry received by a consulting engineer in Montreal was for no less than 250,000 miles of cable exceeding in price $10,000,000. Tremendous quantities of material are required by the French State Railways, including:

Wheels for locomotives.

Wheels for freight and passenger cars.

Straight axles for locomotives, freight and passenger cars.

Bent axles for locomotives.

Locomotive steam cylinders.

Cast steel lubricating boxes.

Cast iron lubricating boxes.

Iron, brass and bronze castings.

Round, flae and square steel bars.

Steel castings.

Steel billets, spring steel.

Helicoidal and spiral springs.

Steel shapes.

Spikes, cut and wire nails.

Iron fittings, spare parts for freight and passenger cars.

Copper and steel fire-box plates.

Rails, bars and splices.

Traction chains and hooks.

Drawn and seamless steel, copper and brass tubes.

During September enquiries were received at the French Chamber of Commerce for shoes, hardware, lumber, foodstuffs, canned goods, prepared furs, glassware for electric light, lard, bacon and smoked ham, toys, maple syrup and tree felling and cutting machines.

The present demand for window ashes and doors alone in the devastated areas in France would supply a splendid market for Canadian factories, but as Senator Beaubien pointed out, prior to the war and even up to two years ago, the major part of ready-made wooden doors sold on the Canadian market were manufactured in the States; most of them came from the middle West, many even from the State of Washington. A substantial proportion were made out of Canadian lumber. In other worls, American doors dominated the Canadian market despite the fact that these articles had to bear the extra cost of long railway haul and of Canadian duty which alone added practically one-third to their cost price. The reason for such an extraordinary state of things Senator Beaubion declared was the failure of Canadian manufacturers to Standardize their products. As he said, "with their enormous markets the Americans can specialize in one product and by producing enormous quantities reduce cost price to a minimum." Standardization is one of the outstanding features of British and American trade preparations. The question should be given the earnest consideration of Canadian manufacturers.

JAPAN BUSY LOOKING NOW FOR OPENINGS FOR HER EXPORT TRADE

AGENTS of Japanese syndicates are reported to be negotiating for the purchase of a large number of mines, flour mills, brick works, saw mills, and other industrial undertakings; while commercially they are making every effort to extend their influence. The Japanese firms, which for the most part have only recently been established at Vladivostok are enlarging their operations and endeavoring to secure as large a share as possible of the trade of the territory. The scouts of these firms are reported to be scouring the country for scrap iron, hides, wool and other Siberian and Manchurian products required in Japan. Since the outbreak of the war Japanese products have been exported to Siberia in large quantities, and are to be seen in all the shops and in the bazars. In comparison with the same period last year the figures for the export of Japanese goods to Siberia show an increase of 687,628 yen.

Wages Question Decided at Ottawa.

Provision Made for Altering Scale According to the Cost of Living

The Labor Board of Appeal's report in the appeal of several Toronto firms, members of the Employers' Association of Toronto, from the award of the Board of Conciliation which considered the dispute between the firms and their employees, blacksmiths and engineers, was made public to-day. It shows that the report of the Board of Conciliation has been modified in a few respects to the benefit of the appellant firms. The Board of Conciliation granted the boilermakers an advance of 3½ cents, bringing their rate to 58½ cents per hour. The rate of pay for general blacksmiths is reduced from 68 to 62½ cents per hour. and forging machine operators reduced from 60 cents to 57½ cents per hour per hour, and with these amendments the schedule fixing rates of pay is confirmed, and men at present receiving more than these rates shall be reduced. The Board of Appeal confirms the decision of the Conciliation Board granting ten per cent. extra to night shifts. The employers also appealed the decision of the Board of Conciliation fixing August 20 as the date on which the increased wages should take effect and providing for the revision of rates at the end of six months, if the rate of living is increased. The Board of Appeal considers that the word "increased" should be struck out and replaced by "altered" in order to provide for a reduction in the wage scale if the cost of living should decrease.

European Events and War Contracts.

THE falling down of the German war machine has come with the earmarks so characteristic to the breaking up of a hard winter. Just now the German war lords are fighting with their backs against the wall, and the appearances indicate that the dynamite is well and carefully laid to blow down the wall.

The world hardly realized what a tower of strength Austria-Hungary had been to Germany until the former quit. Germany was regarded as holding up the dual monarchy, while as a matter of fact Austria-Hungary was the great and effective buffer that kept the Eastern frontiers of Germany immune from attack. That buffer has gone. Turkey has gone absolutely and without a squirm by way of protest. Bulgaria led the procession.

Stripped of her allies, Germany stands alone to face the fury of an aroused and outraged world. If the Hun wills to fight on, then the Hun must have counted the cost and decided to commit national suicide.

The moment the German army came to a standstill it was beaten, for it must be remembered that it was a war of conquest, and not defence, that called the Potsdam war machine to action. The moment the German army got word to retire, that was the beginning of the end, for an army bent on conquest, by its first yard of retirement announces to the world that it has failed in its mission and purpose.

The empire-shattering events that are going on in Europe have their sequel in the commercial and industrial world. They have their touch on the situation in Canada. They reach the machine tool trade, the supply trade, the mechanic and the unskilled employee. They have all to do with the ushering in of that period to which we refer now as reconstruction, the turning from war work to the industries of peaceful days.

Making munitions has been the means of good money for Canadian shops and Canadian mechanics. But Canadian shops and Canadian mechanics do not want to make munitions any longer than the necessity of war calls for them. The turning out of munitions is the carrying on of war, and there is a tragedy, unwritten at the time, in every shell that leaves the lathe, and sorrow and desolation in every bit of shrapnel that passes the inspector. A mechanic may regret the passing of a form of employment that has meant good money to him, but no mechanic worthy of the name of a man could wish the war to continue in order that his employment at good wages might be projected on indefinitely into the future.

The end of war contracts, though it has not come yet, is in sight. It is not going to take the manufacturers by surprise. They have been looking forward to it, and many of them have planned carefully to fit their business relations to the new conditions.

The panic that marked the opening days of the war will not be repeated unless all signs fail and people lose their heads entirely. The population of the world will still need things to eat and to wear; they will need machinery, and they will need buildings. The sun will probably continue to rise in the east and set in the west, and the chances are that the North Star will remain in the north. Folks will probably go to bed at night and get up in the morning as per usual, and the head of the house in this land will sift ashes and crank the furnace as per usual. Don't let the panic idea get into your head. It's not going to come unless you go out and put a rope around its neck and haul it in.

Coal Bins and Church Union.

THE Protestant churches in Brockville held union services last winter. It may have been that they were forced to do this because there was a shortage of coal. Against this, however, is the fact that they are doing it cheerfully on a large scale this winter because they want to do it, and have sent a letter to the Ontario fuel controller pledging support.

This sort of business is liable to do quite a heap of good apart from the coal that will be saved, and that should amount to quite a bit, for the average sexton is a pretty fair stoker when it comes to burning coal.

The Presbyterians may possibly happen to find out that the Methodists are not half bad, and the Methodists may in turn wise up to the fact that the Baptists are not such a poor sort when they get a close-up view of them.

Not only so, but it must be some satisfaction for the pastors to get a chance to preach to a full house now and then. If there's anything that should put a preacher in shape for tremendous action it is a full house. If there's anything that would put the damper on this eloquence and the cold water on his fervor it would be a complement of empty seats. Somehow we've always felt sorry for the pulpiteer who has had to start his day's job with that won't-you-move-up-to-the-front look on his face. He may get off to a good start and keep going right to his "in conclusion," but at the same time he's got a handicap against him that puts him in the class of a lame horse pulling a stone boat.

By all means let the church goers save feul. Let the Baptists sit in tight up against the Methodists, and let the stalwart Presbyterians be sandwiched with the Congregationalists. Nothing will harm them. Let them vie in matching pennies on the collection plate. Let 'em lift their voices higher than the rafters in praise and worship.

If this coal famine keeps up much longer we'll have a real church union. If all these doctrinal hair splitters can live happily together during the cold months of winter, you won't be able to keep them apart during the happy months of the spring and summer.

ADVICE received from a very reliable source at Ottawa intimates that Cabinet reconstruction will take place there within a few days. It is to be hoped that the business interests of the country will be strongly represented. There has been a serious deficiency at the capital in this direction, and it should be remedied. Industrial Canada will need a strong representation to state its case in the after-war problems. It's no job for a weakling, and it's so great a proposition that a little man would hardly dare tackle it.

Some chap in Austria wants to govern the German nation when the Kaiser quits. If he's really in earnest for that job he'd better apply to the Allied custodian of alien enemy property.

Is Power Rationing Needed.

THE insistent cry for more power from the makers of war necessities can be met in only one way. During the coming winter it is hardly to be expected that more power will be available and the only wise and reasonable course is to rightly use that available. Anyone acquainted with the situation existing to-day knows that the munition load, though large, forms but a part of the total power consumption and the curtailing of the energy supplied to makers of household goods, amusement devices, and luxuries of all kinds, would go far towards the releasing of power for the steel plants, abrasive industries, carbide and cyanamide makers, and other industries which make North America dependent in no small degree upon the Niagara district.

This rationing, while just and equitable in itself, would work to the advantage of the country in another and perhaps more tangible form. The labor situation is, to say the least, serious, and any curtailment in the production of non-essentials, automatically releases workers for the vital war industries. People can very well do without pianos, talking machines, and the like for a few months, and can easily purchase them after the war, when their manufacture will help in the necessary readjustment.

The home, too, might well be put on light and power rations. The Tuesday morning ironing bee in the home means an extra 16,000 kilowatt load on one of the Niagara systems alone, and no effort is being made to curtail the sale and use of electric appliances for the home.

Hand in hand with the equitable allotment of the white coal goes the need for more energetic measures for coal conservation. We are to a large extent dependent upon our southern neighbor for our coal, and the least we can do is to use it as efficiently as is being done in the United States. A questionnaire, such as they have sent out to the power plant owner is unheard of in Canada, and the rigid inspection of the individual power plant by government officials evidently has never been thought of. A plant owner faced with the complete stoppage of his coal supply through his own careless ways of burning coal is extremely likely to take an active interest in his boiler room and its equipment. A CO_2 apparatus then is looked upon as a life saver, and other means of checking plant waste likewise.

The Kaiser a Plain Murderer.

WE have been accustomed of late to speak of the prospective surrender of Germany. As far as the German is concerned there should be no terms.

It is quite clear that the Allies do not intend to treat with the Kaiser. What then is to become of him? A kicked-out monarch is too dangerous to be at large. If he is allowed to remain in Germany he will hold to him a retinue of followers who will constitute a hot-bed of plotters against any form of government that would overthrow the German autocracy.

Were the question put to a dozen men, "What would you do with the Kaiser?" the replies would run the gauntlet of excesses.

The German ruler stands right now convicted of murder a million times over. Why should he not face the charge, then, the same as any other individual? If a man kill another in this land he is convicted of murder and is executed.

Why, then, is the murderer of a million any the less a criminal, and worthy of death?

One Grand Old Custom.

OH, things change fast in these here days, they're most peculiar times, and its hard to keep your ways and thoughts from draggin' on the lines. Why, things what was quite new and fresh a day or so ago is set kerchuck inside a day at the bottom of the row.

Why, clothes that wimmen used to wear, the latest thing in style, if we should see 'em nowadays we'd heave a husky smile.

Likewise the men they used to wear chin whiskers on their face, and sproutin' these here ornaments was like unto a race—but nowadays they whack them off and all our young man grows is a tuft about one inch across a-settin' 'neath his nose.

Folks used to get a paper 'bout once or twice a week, and through the columns of the thing both up and down they'd seek—they knew most all that paper said, they was full up with news, and likewise versed upon all stuff like Grit and Tory views. But in this here fast and dizzy age a sheet comes out at dawn, and 'fore the kettle's on at noon the thing is old and gone, and noon editions have a spell, they live for half an hour, but 'round at six they're greeted with a look what's cold and sour.

And youngsters used to learn to play pianers fine and grand, but now they pay their 30 cents for music rolls what's canned.

But there is one old custom, more glorious than the rest, that stays in favor in the north, likewise the east and west—when winter time comes 'round each year 'tis then it thrives for fair, when father slides down cellar and sifts the ashes there.—Ark.

STUDY PROBLEMS THAT WILL COME AT END OF THE WAR

ABOUT forty persons, including representatives from the Canadian Manufacturers' Association, the Canadian Reconstruction Association, and organized labor, were present at the conference at Ottawa last week to consider reconstruction problems after the war. Among those present were Senator Beaubien, Senator Nichols, Major Anthes, James T. Gunn, Sir Alexander Bertram, A. D. Huff, H. P. McNaughton, W. K. George, J. G. Hay, A. H. Brittain, R. Jamieson, George Henderson, Sir John Willison, S. R. Parsons, and a number of others.

The declared object of the delegation was to lay suggestions before the government looking to the formation of a strong committee to cooperate with the government in a definite scheme which would form part of a broad plan of reconstruction after the war, the particular aim of the manufacturers represented on the delegation being the extension of the export trade. Premier Borden said he cordially welcomed the important interests represented and invited them to name a committee to meet with the Reconstruction and Development Committee of the Senate, which has been considering some of the problems referred to. The choosing of the committee was left in the hands of Senator Nichols, and when his work is complete it will be called together in Ottawa to formulate a scheme to put before the government.

After the meeting with the government a further meeting of the delegates was held at the Chateau Laurier, at which they heard some particulars of the Lyon's Sample Fair, which has been held at Lyons, France, for the past three years, and which was instituted to replace the Leipsic Fair.

The first year of the Lyons Fair it was made up largely of French exhibits, the Allied and neutral nations contributing not over ten per cent. of the articles shown. Since then interest has increased greatly, and the percentage of allied and neutral exhibits also. Last year they were thirty per cent. of the total. There was practically nothing from Canada. At the fair which will be held next year a fair amount of space has been secured for Canada, and it is hoped that a fairly good exhibit of a composite character representing the products and produce of the factories and farms of Canada will be shown. The Dominion Government is bearing the cost of transportation of the exhibits from the Canadian seaboard to Lyons, as well as any charges for space at the fair. After the exhibits have been shown at Lyons it is intended that they shall be taken to the fair at Milan, Italy, and from there to London. The amount of business transacted through the Lyons Fair has grown very rapidly. Last year it amounted to one hundred and fifty million dollars.

Getting in Shape for the Coming of Peace

Machine Tool Trade Reports Falling Off of Orders For War Shops —Some Form of After-War Price Control is Looked For—Scrap Prices Are Likely to Drop Soon

EVENTS that are transpiring in Europe are having their effect on the machine tool and supply trade this week. There is nothing surprising in that. In fact the trade is right now going through the successive stages that had been anticipated. There are lines in which it can be said that the passing from war to peace footing has been partially accomplished. Panic talk is not heard. Of course there are industries that are so outstandingly war favorites that they will pass away when peace comes again, but this group is in the minority and is prepared for its fate.

There seems to be a growing feeling that there will be some measure of control in regard to the steel and iron situation after the war has ended. Such a measure would have the effect of lending a desirable stability to a situation that might otherwise be uncertain and panicky. Reports from United States indicate that some form of control will be maintained from Washington while business is getting on a peace footing. The feeling is that with some such body setting the standard of prices it will be a much easier matter to avoid cutting prices to points below cost, and it will allow firms to dispose of their war-price stock without having to go out of business.

The demand for machine tools for war plants is practically at a standstill. Sales of supplies are better but inclined to be spasmodic. Munitions plants are not stocking up with supplies but are buying for actual and immediate needs.

Jobbers are running low on stocks of steel plate. In fact it is hard for them to restock at present, and they are not inclined to do so considering the difficulty that is met with in getting material from United States points. They are satisfied to approach the coming of peace with warehouses as near empty as it is safe to run them.

Machine tool dealers in Canada come under a recent ruling made in United States in regard to "stock" orders. The practice in the trade has been to place orders for machines and then sell them. Now no order can be placed that is not backed by a bona fide sale. This ruling will make it harder for the dealers to do business for the time being, but it will also do much to keep them from facing peace with a lot of single-purpose machinery on their hands, and it will also go a long way in cutting down the avalanche of cancellations that otherwise might follow in the wake of peace being announced.

Scrap dealers are to all intents and purposes out of the market. The prices have not actually slumped yet but every indication points to a moving to a lower plane in the very near future. Scrap metals are now about 85 per cent. above pre-war prices. Copper, for instance, was worth about 14 cents before the war, while now the United States government fixed price is 26c. Scrap prices are likely to come down, and as a result there are many sellers on the market now but few buyers, and sales are made only for special and urgent cases.

LIGHTER VOLUME OF BUSINESS NOTED IN MONTREAL THIS WEEK

Special to CANADIAN MACHINERY

MONTREAL, Nov. 7.—With every day bringing new but not unexpected surprises it is natural to find that industrial conditions are more or less affected. The encouraging news from the front has created a situation that time alone can define. That munitions making activity should be first to feel the reaction of the peace movement is expected, and nervousness is shown in shell-making circles as to the early possibilities in this connection. Despite the restricting influence of the influenza, the subscriptions to the Victory Loan are flowing in regularly, and its importance is clearly shown over all other activities. The markets generally are feeling the inevitable results of peace possibilities, as shown in the lighter volume of future trading. Machine tools are quiet with shell demand almost eliminated. Old material business is almost stagnant from the dealers' standpoint. The metal markets are operating on a normal basis with little of feature to report. Under existing conditions quotations are given as a nominal guide only.

Steel Still Active

Developments in the war situation are tending to unsettle the trade, but this so far has only shown on the surface as activity in all quarters is apparently undiminished. Steel output is still insufficient to meet the requirements of present demand. Some dealers have been hoping for relief in the getting of steel owing to the possible early falling off for war purposes, but little indications of such conditions are shown in the attitude of the War Board as restrictions on the distribution are as firm as ever. Even should peace materialize out of present developments it is not likely that immediate relief would be given to steel consumers unless it be in the direction of heavy steel bars now utilized for shell material. The demands for plate and structural steel will probably continue for an indefinite period, so that a return to pre-war conditions will be a matter of many months, or perhaps years. Another factor that will influence the post-war activity is the retaining of the present boards for the purpose of adjusting, gradually, the existing system to meet the needs of future requirements. The tendency is to ease up on shell production, and this has been reflected in the suspension of new activities in this district. Plants now working on American shells expect to complete their initial contracts but are not antcipating renewal orders. It is understood that some orders for supplies are being placed with cancellation clauses to guard against possible contingencies. Local dealers are still looking to the War Trade Board for their steel requirements, and conditions here are virtually unchanged, with prices, apart from those under direct control, on a nominal basis.

Little Demand for Shell Machines

Despite the quieting effect that approaching peace possibilities have had on the general industrial situation, the enquiries for machine tool equipment are still of fair volume but showing a tendency for domestic tools rather than special machines for shell manufacture. The principal feature in connection with present condition is the falling off in the placements for munitions equipment. Those tools that have been waiting delivery are coming along with fair regularity but little business of a new character is reported. This must be expected in face of the rapid developments that are likely to change the early future prospects as regards war materials. No sudden cessation of shell making is anticipated, but new plants now under consideration, or the placing of new orders, will doubtless be deferred for a period. It is understood that one large contract for the American government that would entail the erection of an entirely new plant, has been held up pending early developments. The general machinery market is quiet, with business relatively light. Prices are likely to ease up early in the new year.

Dullness Still a Feature

Dullness continues to characterize the general scrap situation, and if anything, is more emphasized than last. Few consumers are in the market for large supplies of material, and what business is passing is confined to small lots for jobbing foundries. The mills are taking only what they require for immediate needs and demand for future delivery is practically nil. The situation here might be summed up in the statement of one dealer, that "we are not selling a solitary thing." This of course refers to relatively large sales, some light orders still being placed. The controlling factor appears to be the unsettled condition of the trade as a result of the present European developments. This uncertainty will tend to maintain the present nervousness. Dealers are anticipating a decline in scrap prices, especially in irons and steels, but are holding to the present nominal prices until something turns up on which they can base their further adjustment.

TRADE PASSING FROM WAR BASIS

U. S. Order Re "Stock" Orders Clears The Decks, If It Does Make The Going Harder

TORONTO. — The whole trade, machine tool, supplies, steel, scrap—in fact any industry that has been affected by the making of munitions, watches the situation on the western front, in Austria, Turkey, and every place where the quick-changing last act in the war drama makes more certain the near approach of the time when business will have to be recokened with from the angle of peace-time competitive trade. We say competitive trade because the element of competition in war trade has been largely eliminated.

The idea that there is going to be panic is being discounted by men who are giving a great deal of attention to the matter. They have, in many cases, brought their business affairs to the point where the load is not heavy, and in other cases they have been aided in this by some of the latest regulations that have been put into effect by Washington.

Machine tool supplies are quietier in demand. There has been a falling off in the inquiry for new equipment. The dealers in scrap metals report that they are largely out of the market, because there are more sellers than buyers, and they are overstocked now. But these conditions have been anticipated, and the business executives have not been napping or sleeping at the switch. In many cases the businesses have passed into the first stages that were anticipated following the declaration of peace.

In Machine Tools

Dealers in machine tools can readily see where the war business is falling away. They report no inquiries for new plants during the week, and as yet selling for after-war trade has not commenced in earnest. The action of United States War Industries Board in cancelling "stock orders" for machine tools has cleared the decks as far as a great deal of business handled by Canadian dealers is concerned. There were firms in Canada who some months ago were placing orders heavily in United States against dates as far removed as June 1, 1919. It is probable that in the aggregate this prospective business placed in U. S. shops would amount to many hundreds of thousands of dollars. It has been the best way that the Canadian dealers could book business. They would order the machines first and then proceed to sell them, quite secure in the anticipation that there would be a market for their holdings. It was an easy matter to approach a prospect with the suggestion that you had a machine on order three months back, and that he could get this by securing the necessary priority and license. It was much easier than to approach the customer with the information that you would have to take his order, secure the necessary papers and information, and then go to the makers of such machines and see what could be done in the matter of deliveries. The latest ruling has practically cleared the Canadian houses of anything but real bona fide business. Although it may work out a bit rough in a few cases, it will be a blessing in others, and on the whole will add a degree of stability that could not otherwise be secured. In one way it backs up the policy that has been adopted already by some of the larger firms of "no cancellation." It will tend to give a clear sheet to work on. Had the machine tool manufacturers found their books full of cancellation business on the conclusion of the war they would have been faced with a serious problem, because the cancellations would follow on through a good many shops in which part of the work had been carried on, and there would have been a great deal of readjustment, much of which would not be satisfactory.

The Supply Business

The machine tool supply business may well be described as spasmodic. One week the bookings are good, the next week they are equally bad. Munition firms are not buying supplies at the rate they were a few months ago. There is a very marked tendency to adopt a pretty close policy in this regard. Of course there are shops that have contracts where they know they are well protected against any investment they may make with regard to equipment or supplies, but in the majority of cases the policy of buying well ahead is not being followed in the munitions plants.

The Steel Trade

The day of ten cent. steel is almost done for. That is the opinion of the trade, and the trade is glad of it. Two hundred dollars for a ton of steel is a fictitious price, and it cannot long survive. The jobbers have faced a dangerous situation. There has been a lot of business offering even at ten cents a pound, and dealers have been quite safe in buying at a price that ran around 7½c. The danger came in being overstocked when the time should come to meet the 3¼c. price at the American mills. It has been so difficult to secure material that there has been little chance to stock up very much. Jobbers have let their plate stocks bought at fairly high prices run out almost to the point of exhaustion, and they consider that it is good policy on their part to keep these stocks right there until there is something more definite in the way of new prices. There is a feeling, quite marked too, that the War Trade Board, or some organization of a like character may remain in power for some time following the war, to consider and equalize prices. A statement by Hon. Mr. Ballantyne only a few days ago intimates that there will be a drastic readjustment in the price of plate. The government right now recognises $150 per ton at the mills for plate, while the price arranged for the new mills at Sydney, for ship plate is $83. Small wonder that the dealers are working on the

POINTS IN WEEK'S MARKETING NOTES

Scrap metal dealers state that they are practically out of the market. Prices now are on an average 80 per cent. above pre-war figures, and dealers do not want to be carrying these high value materials when the time comes to sell into a peace time market.

—

Machine tool dealers report that there are very few inquiries for new equipment for the turning out of war work.

—

Business in supplies for munitions plants is spasmodic. Most of the shops are not carrying much stock, and only place orders for immediate needs.

—

Dealers in steel plate believe that the day of 10 cents per pound sales is about over, and in nearly every case the stock has been allowed to reach a low level, so there will be little of this high-priced plate on hand when lower levels are reached.

—

The experience of the past week shows that it is harder than ever to secure material for anything but straight war work. A large gas company was refused steel plate for repairs to existing equipment. The same thing happened some months ago, but at that time the company secured statements from many munitions plants stating that gas was essential to them, and the steel material was forthcoming.

—

New York reports that there has been a decided falling off in the volume of business for war shops being placed by the United States government this week.

—

Pittsburgh believes that the War Industries Board, perhaps in some modified form, will remain in existence for some time to regulate prices at the conclusion of the war.

policy of hand-to-mouth until the situation has been ironed out more satisfactorily.

There is no betterment in the steel supply coming to Canada. A large gas company was refused plate for repair work. Not long ago this same concern was turned down at Washington because the authorities there held that gas plants were not necessary to the production of munitions. The management immediately secured the statements of a number of munitions manufacturers that gas was very essential, whereupon the needed material was secured.

Full Up On Scrap

"For the greater part of last week," stated one of the big dealers, "we were out of the market entirely. We are not keen to buy now. In fact there are lines that we would not purchase at any figure. Our whole premises are loaded to the ceiling, and we will not take on anything else. The whole trend of events and of feeling in the trade points to lower values, although the prices quoted now are nominally correct. The situation is this," he continued, "prices are now too high for commercial business. They are, on an average 85 per cent. above the pre-war figures, and we are not going to buy at war prices and hold to sell into a lower after-war market. Copper and spelter set the pace for the yellows, so brass follows. Copper, as a general thing, is the big end of the scrap metal business, although according to the stocks at the foundries, steel and iron are a close second at times. The average price of copper before the war was around 14 cents per pound, while the price fixed by the United States government at the present time is 26 cents. There are large quantities of scrap offering for sale. We don't want to buy and we may as well make our position definite in the matter."

COMING OF PEACE FELT IN NEW YORK

But Large Orders Are Still Being Placed For War Plants Here

Special to CANADIAN MACHINERY

NEW YORK, Nov. 6th.—The coming of peace with rapid strides undoubtedly creating a conservative feeling throughout the machinery industry but there is a wide difference of opinion in regard to the ultimate effect upon manufacturers. Although the volume of business has been reduced somewhat by expectation of less activity in war preparation, it is notable that important contracts for machine tools continue to be placed by the Government and by war munition plants. Some cancellations of orders previously placed indicate that extensive programs for ordnance will not be carried out as originally intended, yet heavy purchases will be made in the aggregate for some weeks longer.

The Emergency Fleet Corporation has cancelled equipment orders for the proposed Scott boiler plant of the Barber Asphalt Paving Co., at Maurer, New Jersey, and also for tools designed for equipping Government owned shipyards in various stages of completion. Already, steps have been taken to suspend the construction of wooden ships at the Kearny, New Jersey plant operated by the Foundation Co. Before the first of the next year the Foundation Co., will have completed the building of ten Ferris standard type ships at the Government yards built on the property of the Ford Motor Co., but orders for other wooden craft to be built at this plant have been cancelled; large numbers of workers have already been laid off.

From information which CANADIAN MACHINERY received from Ottawa before going to press, there had been no cancellations of munitions contracts made yet. However, the feeling at the capital is that this move will be made in the not distant future, should the situation on the Western front remain as favorable as it is at this writing. Local munitions firms are in much the same position as Ottawa, but in the meantime capacity production is the watchword of the shops.

Purchases of several million dollars worth of hydraulic forging presses have been made by the Government for equipping various munition plants throughout the country to pierce hot ingots for shells. Orders were also placed for the same plant for several hundred thousand dollars worth of pumps and accumulators.

The placing of additional contracts for 4,000,000 semi-steel shells by the Government is also announced and several of the manufacturers receiving these orders are buying machine tools. The Kansas City Hay Press Co., is to make 2,000,000 155-m.m. shells, the Pittsburgh Iron & Steel Foundries Co., Midland, Pa., will make 250,000 8-inch shells and the Kohler Co., Kohler. Wis., will manufacture 200,000 155-m m. shells. The Massey-Harris Co., Batavia, N. Y., has also received a contract for semi-steel shells.

The Singer Manufacturing Co., has made additional large purchases of ma-

WELLAND MAN'S VALVE MEETS WITH BIG SALE IN WAR PLANTS

A. L. CALVERT, 60 Randolph street, Welland, chief engineer of the Canada Forge Company, has invented a hydraulic operating valve which will make his name famous, and if it does not make him rich it will be a wonder.

This valve, which was designed to ease the operation of shell making, was perfected last March, and the first one was installed at the Canada Forge plant. The invention met with an instantaneous success. It was taken up by the Imperial Munitions Board and the Imperial Ordnance Board, as well as the United States Board in charge of munition making.

The result, says the "Welland Telegraph," is that eight firms are engaged to-day in making the Calvert valve.

The selling price of the device is $1,040.

Invention Meets With a Remarkable Reception

Among the Canadian installations are the following: Canada Forge Co., 15; British Forgings, Toronto; the following Montreal firms, Peter Lyall & Son, Fairfax Forging Company, and Dominion Bridge Company; the Goldie McCullough Co., Galt.

Last week 45 valves were installed in the Symmington Forge Company's plant in Rochester, and this week a similarly large installation will take place in a large Chicago plant.

The valve used formerly to operate presses in shell making was packed with leather. This packing had to be replaced every few days, causing a delay of some hours, not only to press, but to the whole unit engaged in the operation. With the increasing cost of leather the leather bills ran into thousands of dollars.

Mr. Calvert set out to perfect a valve that would eliminate the use of leather and advance operating time to one hundred per cent.

Inventor Nearly Floored

He got the idea of the valve and had it completed, but he came to a full stop when he came to devise a plan to connect it up. He worried over this for weeks, until finally he was in very poor health. His doctor told him he was worrying about something, but Mr. Calvert gave no inkling of the secret. One day at dinner the idea of the connection came across him like a flash. In a few days the first valve and connection were completed and installed at the Canada Forge plant. Soon fifteen Calvert valves replaced the ones previously in use. Inspectors for the Imperial Munitions Board saw the valves and what they were doing, and now all the munitions plants are being fitted with them as fast as they can be installed.

First Valve Has Never Lost a Minute

As the first valve was put in operation only on the 15th of March last, the success of Mr. Calvert's invention must be put down as one of the largest successes in the engineering field. That first valve, it is interesting to note, has never been a minute out of commission since it was put in.

The device is very simple in operation. A small lever lets loose a pressure of from 250 to 500 tons as is required.

Mr. Calvert has sold the American manufacturing and selling rights to the Southwark Foundry and Machine Company of Philadelphia, and in Canada the machine is made by the Imperial Manufacturing Company of Welland.

After twelve years with the Canada Forge Company, Mr. Calvert now finds it necessary to devote practically all of his time to the immense business developed by reason of his invention.

chine tools for equipping its Elizabeth, N. J., plant for the production of gun recoil mechanisms. The J. L. Mott Co., Trenton, N. J., that will concentrate on fuse work, has purchased fifteen lathes and other tools. The Symington-Anderson Co., Rochester, N. Y., is adding twenty tools to its gun plant. The Bartlett Hayward Co., Baltimore, and Sprague works of the General Electric Co., at Bloomfield, N. J., that are concentrated on Government work, have been buying supplementary lists of machinery.

The Holt Manufacturing Co., Peoria, Ill., has concluded the purchase of $500,000 worth of tools for the manufacture of caterpillar tractors and the Ordnance Department of the United States Steel Corp., has made additional purchases of machinery for the Neville Island plant, including large gun-boring and turning lathes. Equipment orders thus far placed for this plant call for the expenditure of $10,000,000 and a large number of small and medium size tools are still pending. Buying of machinery for the 16-inch howitzer plant at Nicetown, Pa., however, is held in abeyance awaiting instructions from Washington. Included in the $130,000,000 purchases of motor trucks and similar equipment by the Motor Transport Corps are $12,000,000 worth of class B motor trucks; these latter orders were distributed among seven different manufacturers, including the Republic Motor Truck Co., Alma, Mich., which will build 2,000, and the Denby Motor Truck Co., Detroit, 1,500. The Stutz Motor Co., Indianapolis, has taken an order for 200 artillery tractors.

Large allocations of rails, shell steel, and shapes for the manufacture of 40,000 cars have been made by the Government.

GOVERNMENT CONTROL MAY LAST AFTER PEACE IS SIGNED

Special to CANADIAN MACHINERY

PITTSBURGH, Pa., Nov. 6.—Disguise may be attempted, but the great question before the iron and steel trade in the past week has been the matter of prospective prices. Military developments have come rapidly, and it is the cessation of firing, when armistice terms are such as to prevent its resumption, that marks the advent of peace from the business man's viewpoint. In considering the matter of prices, and of control or regulation of business generally, it is important to have clearly in mind the difference between peace from the commercial world's viewpoint and peace from the diplomatic viewpoint. Diplomatically, peace will not come until the President has issued his peace proclamation, which will be many months after the cessation of hostilities. All the war instrumentalities that have been created by authority of law will continue in existence, and doubtless with full legal power, at least to the declaration of peace by Presidential proclamation. The Railroad Administration, the Food Administration and the Fuel Administration, will continue for some time afterwards.

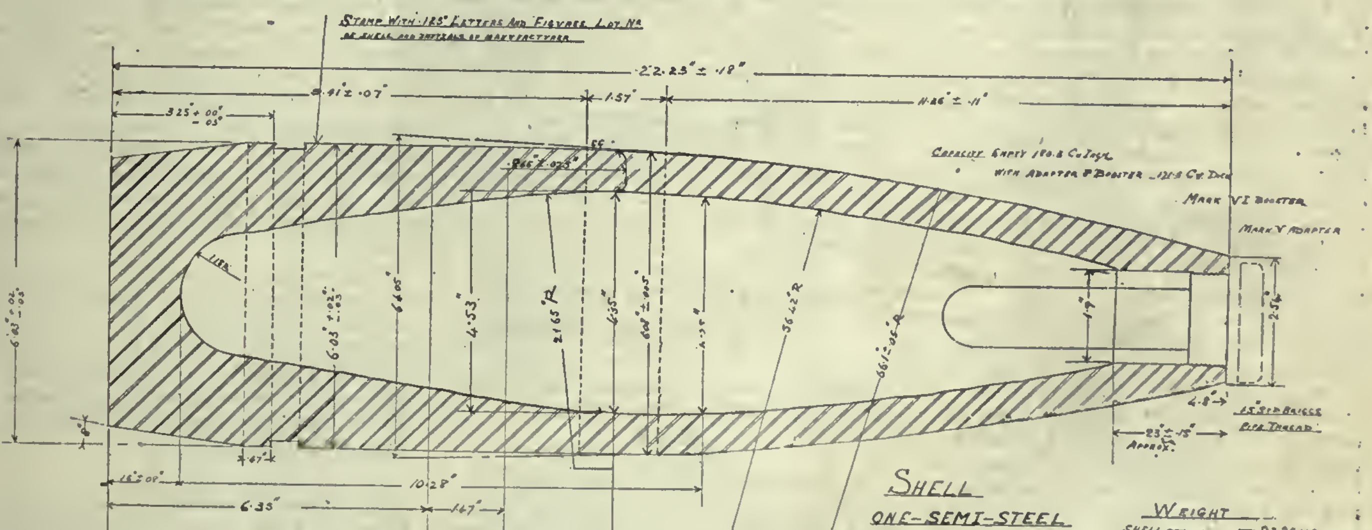
Thus there will be an interim period, from the cessation of hostilities, called "peace" by the business world, to the declaration of peace by the Government. There may be, and probably will be, an interval of several months. Naturally there will be no effort to speed the declaration of peace, but rather the reverse, so as to maintain such war time control of affairs as is desirable.

This separation in the dates of "peace"—commercial and diplomatic—brings to the front the matter of how war time control of industry has been exercised. That which is based on law, like the control of the price of coke, resting upon the Lever Act of August, 1917, the "food, feed and fuel law" is one thing, that which rests upon agreement, like the steel price control, is another thing. The War Industries Board controls steel prices by agreement with the producers. the steel trade has felt strongly all along that control by agreement is better than control by law, and indeed one reason why it accepted control by agreement when it did was because otherwise control by law was in sight, the Pomerene bill being ready for submission to Congress. The matter becomes very awkward, however, at this time, because for war time conditions control was requisite to prevent prices being too high; for the immediate future the steel trade holds control to be desirable to prevent them being too low. It is intimated that the Government agrees. It wants to keep business prosperous for various reasons, one being that it is necessary to collect taxes, and it wishes to avoid a slump or demoralization. Legally, in view of the Sherman law, it is one thing for steel producers to agree not to sell at above certain prices and quite another thing for them to agree not to sell below certain prices.

Government as Buyer

It is hinted that there may be legislation to enable the War Industries Board or some other agency to control

LONGITUDINAL SECTION OF SEMI-STEEL SHELL



Several Canadian shops are figuring on the making of cast shells, and in one case a shop has been started, but that is about as far as the work has prograssed to date. The machining operations much resemble the work on the .155, though of course the work is much more simple. The nose of the gas shell has a longer radius. There are practically no operations on the interior Manufacturers plant to test each shell with hydraulic pressure up to 1,000 pounds, while it is understood that the government test calls for 300 pounds air pressure.

iron and steel prices either way, up or down, but legislation is not always easily secured. There is another contingency, however. In the case of railroad steel and ship steel the Government will continue to be a large buyer, perhaps a larger buyer in these two fields than formerly. If it agrees upon prices that will set a pace. Sherman law or not, steel producers could not be expected to sell to commercial buyers at lower prices than it asked the Government. One could hardly charge that adherence to prices thus approved by the Government constituted an agreement in restraint of trade.

When there is so much confusion, doubt and uncertaintly, there is one clear and important thing to consider in the matter of prospective prices: What will be the Government's attitude as to prices for ship steel and railroad steel? On this subject there is some light. The United States Shipping Board, which controls the Emergency Fleet Corporation, the body that places contracts for ships and controls the shipyards commandeered, has for about three weeks been engaged on a program of revision of the whole operation, the matter being referred to in this correspondence a fortnight ago. There have been developments almost daily. Several contracts for shipyard extensions have been cancelled, also a number of contracts for ships, chiefly wood ships. The spirit in which this has been done has been quite obvious to those familiar with the circumstances, but both Chairman Hurley, of the Shipping Board, and Director General of Shipbuilding Schwab, of the Fleet Corporation, have made official statements which leave no room for doubt. The object is to continue building ships, as many as possible, but to economize, to cut out inefficient operations, which were grasped at when every single ship that could be added promised to be almost invaluable, and at the same time to encourage the building of ships at efficient yards. Mr. Schwab's statement of only a few days ago was that the definite program that had been adopted was to build 15,000,000 tons deadweight, and only 2,500,000 tons, or one-sixth, had thus far been built. The program was to be carried out. This would mean, as the efficient yards speed up still more, that the weekly or monthly tonnage of steel going into shipbuilding would increase for months to come over the present rate.

Thus there is assured a very heavy demand from the Government for ship steel, but obviously a part of the program already well considered is that of getting the steel at the lowest possible price. As already reported, contracts have lately been offered to steel mills with a new clause, allowing the Government to cancel at will. Clearly the object is to seek a lower price whenever circumstances permit.

As to railroad steel the case is equally clear. Long ago prices on all important steel commodities were fixed, with one prominent exception, standard section steel rails. Last September the War Industries Board agreed with the rail mills on prices of $55 for Bessemer and $57 for open-hearth rails, but the Railroad Administration withheld its approval. Of course, it is now more disposed than ever to seek a lower price. Another important fact is that some of the railroads have refused to accept, and pay for freight cars ordered by the Railroad Administration several months ago, its total distribution being 100,000 cars. The railroads that object assert that the prices are too high and they may not need the cars anyhow. They urged the Railroad Administration to pay for the cars out of the "revolving fund" of $500,000,000 provided by Congress for various purposes, and then sell the cars to the roads after the war at what would then be a fair price. Thus one has both the Railroad Administration and some of the individual railroads plainly opposed to the present steel prices, and their attitude assumed before the cessation of hostilities came so clearly in sight. Now, of course, they are necessarily still more strongly opposed.

Thus we have it that the two great fields in which the Government will remain a buyer of steel after the cessation of hostilities, and for quite a period, there is clearly going to be a move for materially lower steel prices. In all the present uncertainty this is something concrete. One cannot attempt to predict how steel prices will range during the period of readjustment from a war time to a peace time basis, but one of the distinct possibilities is that it will be a sort of "waiting market" for the Government to take the lead in developing new prices for ship steel and railroad steel.

As to the present attitude of the steel buying public, that is quite clearly disclosed. All the regulations of the War Industries Board remain in force, of course, but the restrictions have always related to the manufacture and delivery of steel, not its purchase and sale. One is permitted to buy and sell all the steel he likes, as "Class D," which is steel that may be made and delivered after priorities and preferences are provided for (not necessarily filled) so if buyers were eager to get steel without knowing the prospective price, they would be eager to place orders. This is not the case. They are not even enquiring.

CONTRACTS TO BE FOR MORE VESSELS

Outline Given By Minister of Marine Regarding The Future Work

In pursuance of the Government's efforts to establish a Canadian mercantile fleet, the Minister of Marine has now given out contracts for the construction of 31 vessels. These are all steel steamers, varying in tonnage from 3,400 tons to 8,100 tons deadweight capacity. They are of the one deck and two deck type. It is also the intention of the Government to construct a larger class of vessel, reaching a deadweight capacity of 10,500 tons. The vessels will all be built to the highest class of Lloyd's or the British Corporation, and to the requirements of the British Board of Trade, and Canadian Steamship Inspection Board.

There has been some delay in making a start with these vessels, but it has been entirely due to the fact that the building berths were occupied by vessels building to the order of the Imperial Munitions Board. However, these ships are in many cases vacating the ways, and the Government vessels will be laid down as fast as there is available building space. The contracts have been distributed to yards in all parts of the country, though of course, the size that can be built by the lake shipyards is limited to the capacity of the canals.

It is expected that Messrs. Canadian Vickers, Montreal, will be the first yard to launch any of these ships, as they expect to put two vessels, one of 4,300 tons, and one of 8,100 tons, into the water during November. They will be named respectively Canadian Voyageur and Canadian Pioneer, and will have as sponsors Sir Robert and Lady Borden. If all goes well after launching, it is probable that these two ships will leave the St. Lawrence before the close of navigation. During the winter, if deliveries of steel continue satisfactorily, work will have been far enough advanced to have seven or eight vessels ready for service early in the spring, while the whole of the 175,000 tons comprised in the 31 vessels, will be sailing before the end of next year.

Such is the demand for shipping that if it was desirable the Government could dispose of the vessels contracted for at a handsome profit, but such is not their intention. Being now in possession of a national railway system of considerable dimensions, the Minister stated it was the intention of the Government to keep these vessels for the Canadian people, and work them in conjunction with the national railway system. In this connection the railways will feed the ships on their eastern voyages, while the ships will feed the railways on the return voyage. The management of the steamers will be under D. B. Hanna and his staff, and will not be subject to any interference outside of the management itself.

This combination of rail and vessel transportation has worked out very successfully under private management, and if the same success can be achieved with a national venture, it will go a long way to encourage the partisans of Government ownership. However, we must wait and see.

Appointed Director.—At a special meeting of the board of directors of the Independent Pneumatic Tool Company, held in Chicago on Wednesday, October 30, Roger C. Sullivan was appointed a director and elected chairman of the board, also a member of the executive committee, to fill the vacancies caused by the death of the late John P. Hopkins.

Practical System in Factory Operations

It is Necessary to Know Costs by a System That Can Give You Figures at Short Notice—Charts Tell a Story That May Have Its Sequel in Many Other Plants

By M. H. POTTER

A STUDY of all the conditions holding in the old plant must be made before the factory can be placed on a paying basis. A good many make the mistake of starting at once to reorganize one department or one branch without considering each department's relation to all the others and to the parent trunk.

The first step in straightening out the tangle in this factory was to investigate all the conditions. After spending about three weeks investigating these conditions a general plan of reorganization was laid out on paper. The duties of the various persons connected with the heads of the departments were charted, and then, with the whole plan in view the organization was rearranged along the lines shown in Chart 1.

The purchasing agent seemed to have his hands full; he was unable to give proper attention to any one subject. He had some duties in common with other heads of departments. And as the manager of the factory was present only a comparatively short time during the day a great many things were allowed to pass unnoticed. Such a subject as the maintenance of the plant and equipment.

The same men were retained, but the duties and responsibilities of each one were diagrammed so that no misunderstanding could exist. After the whole plan had been thoroughly considered and worked out, blue prints of this chart were made and distributed to each department in the factory. This method of distributing information in the factory was followed by putting any part of the new plan into effect. The head of each department received a bound copy of the methods decided upon so that he could understand exactly his relation to all the other departments and to the work of which he was in charge.

When putting such a plan into effect the hearty co-operation of each individual, which is essential, can be secured by making it of pecuniary advantage to follow out the plans as laid down. The men in charge of departments naturally consider that the plans upon which they were operating are good and do not take

very kindly to new burdens imposed upon them by a reorganization or by the rearrangement of the work formerly handled in their departments. By paying a bonus on daily production the department changes in routine, however, may often be accomplished successfully. After it is explained to the man that he can make more by working out the plan proposed he is not long in deciding that the new plan is at least worth trying out

After a general plan of organization has been developed the second step is to arrange the methods used from the buying of the raw material to the shipping of the product. An easy way to do this is to take some one particular product and trace its course from start to finish through the plant, putting all the different steps down on paper so that the actual routine used in the factory can be seen graphically. After this has been done it will be found that the purchasing and stores department is a starting point for reorganization.

So in reorganizing the factory the start is made with the requisition blank. As no regular system of buying had been in use in the factory the purchasing and stores departments were replanned. When it was necessary for any raw materials, supplies or tools to be purchased it was arranged so that the department head requiring the material was to make out a requisition called a "requisition to purchase" (Form 1). This was sent from the department head to the superintendent for approval. If the cost was considerable this requisition had also to have the approval of the factory manager, and in cases where purchases amounted to over one hundred dollars the general manager of the plant O.K.'d the requisition. The requisition thus O.K.'d was given to the purchasing agent and constituted his authority for making the purchase.

If the item was something which the purchasing agent had no quotations of on hand, a "request for quotation" card (Form 2) was sent to the firm or firms handling the goods required. They had only to fill in the price, sign and return the card. These cards were made standard size so that they could be filed conveniently in the indexed drawer and kept as a basis for price on future orders. After the cards were returned a clerk entered the prices upon a quotation record card for general reference.

When a purchase was to be made the order was sent out on a sheet like that shown in Form 3. Three copies were made, the original going to the supplier. The first copy was kept by the purchasing agent and the third sent to the storekeeper. The latter checks off the receipts on his copy from the receiving report (Form 4).

It had been customary in the plant to call the factory manager, superintendent, or foreman whenever an applicant for employment presented himself. The request for an interview was usually made to the telephone operator, whose desk was near the office entrance. Since she was desirous of pleasing everybody and aiding her friends, the operator would immediately create confusion in the whole plant, if necessary, in her somewhat over-zealous endeavor to locate the department heads.

This plan of hiring men was abandoned. The accounting department was housed in the adjoining room to the entrance as is shown by the office arrangement (Chart 2). The location of the timekeeper was changed and a window was cut in the partition at his back. How the office was rearranged is also made clear. Just above the window was

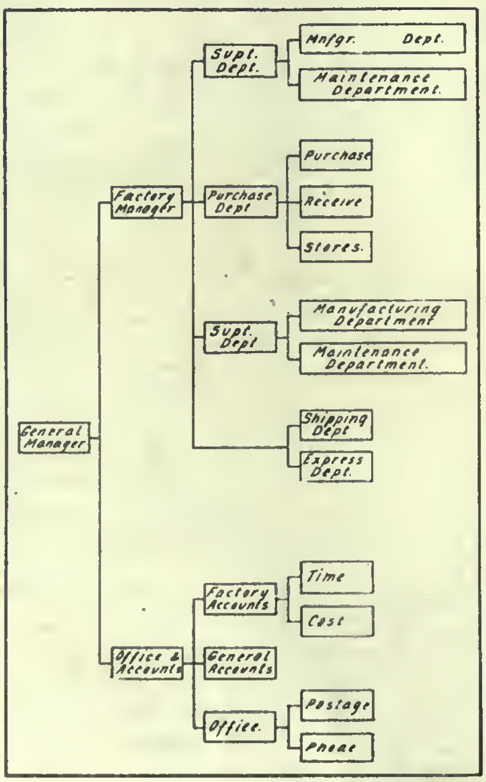

CHART 1

mounted a blue print (Chart 3). This chart was called the "employment chart" and the timekeeper could tell at a glance just what class of employees were in demand throughout the various departments. The employment department was

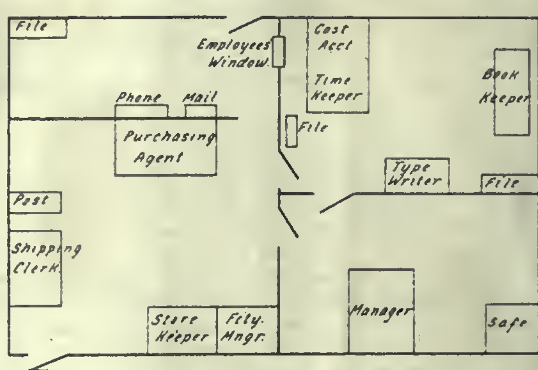

CHART 2

turned over to the timekeeper. Each department head would issue a "requisition for help" (Form 5) when in need of help of any kind. One of these requisitions was issued for each person desired. Upon receipt of these the timekeeper would place a peg or glass-headed push-pin in one of the squares opposite both the department and the class of employees.

When an applicant presented himself it was a very simple matter to tell whether or not he was needed. If not, he was requested to fill out an application as shown by Form 6, providing the timekeeper thought that the company would ever care to engage him.

SPONTANEOUS COMBUSTION OF COAL

It has been shown by experiment that the sulphur contained in coal in the form of pyrites is not the chief source of spontaneous combustion, as was formerly supposed, but the oxidation of the sulphur in the coal may assist in breaking up the lumps of coal, and this may increase the amount of fine coal, which is particularly liable to rapid oxidation. Even this opinion is not unanimously endorsed. In spite of experimental data showing that sulphur is not the determining element in spontaneous combustion, the opinion is widespread, if possible, it is well for storage purposes to choose a coal with a low sulphur content.—M. E.

The Employment of the Returned Soldier

The Following Article Gives an Interesting Resume of This Problem as Viewed by an English Correspondent of the Engineering Supplement of the London Times

WITH the manhood of the whole nation in arms so far as it is of military age, the reintroduction of the nation's soldiers into industry will be a far-reaching problem. It will, indeed, not arise for solution until the war is over, but then there will be no time for working out plans to ensure that this indispensable process will be done thoroughly and efficiently. In the interest both of production and of the producers, the plans for assuring this will need to have been matured before the time arises for putting them into operation, and there will be no industry that will not, in greater or less measure, have to be prepared with its programme.

But in the meantime the employment of discharged soldiers includes an instant problem, which has now been long before manufacturing industry, and is daily increasing in volume—the problem of employing men from the Services who are discharged through being no longer fit for military duty. The engineering trades in particular, which are for the time being the backbone of British industry and the most certain source of employment, are badly affected by this problem, and the methods by which it may be solved are all the more interesting because of the somewhat similar problem on a vaster scale which these trades will have to face when the war is over.

Kinds of Disability

Men may be discharged from the Services for various reasons. The typical case is, of course, that of men who have lost one or more limbs or eyesight. No class of workers can more deserve attention; and it is satisfactory to note that no class appears to be more in the way of getting it. It may perhaps be too early to say how far the great ingenuity that has been spent on devising mechanical means for replacing lost limbs has arrived at the best mechanical solution of the problems it has had to consider. By this time many solutions are under practical trial on the persons of large numbers of returned soldiers; and, in the light of their experience, it should be possible to arrive at something like standard designs, embodying what experience on the unhappily large scale now available may suggest as the best. When this has been done, it will be no less urgently necessary to make arrangements for producing the artificial limbs at a reasonable cost. For the time being cost is doubtless a matter of secondary consequence compared with the importance of giving soldiers who need artificial limbs the best that can be produced with the least possible delay. Once, however, the emergency call is satisfied, the economical aspect will resume its ordinary importance, and it will be the business of those who are in charge of the provisions for supplying artificial limbs to see that the industry is placed on a sound footing in respect of economical production. There is reason to hope that both for discharged Service men who are maimed and for those who have lost their eyesight, enough attention is being paid by enlightened men to make sure that the essential requirements of the situation will be fully met.

Unmutilated Men

It must be remembered, however, that of men discharged from the Services, only a small fraction have suffered mutilation. A large majority have their sight and members unimpaired, and of these a good proportion retain full muscular strength, for either all or many industrial purposes. While, therefore, an essential part of the provision for employing discharged soldiers must lie in finding work that can be done by those whose physical powers are impaired, the problem includes, and consists to even a larger extent for dealing with those who have been released without these disabilities—cases of shell-shock, gas-poisoning, wounds which though they incapacitate men for the violent activities of war, leave them essentially as good as ever for most purposes of the workshop. Such men constitute the large majority of those who have to be reinstated in industry. The figures are not available for showing precisely how many are coming in month by month, but no doubt exists that they are considerable, and are increasing. At the present time most branches of engineering industry are suffering from shortage of labor, and nothing could be more helpful to the engineering trades in discharging their present great duty to the nation than that they should have and make use of a full supply of discharged Service men. Nor, on the other hand, could there be anything more helpful to the men than that they should be introduced into industry at a time when it is most in need of them, and when no economical reason exists for subjecting them to any form of competition such as they will have inevitably to face in ordinary times.

It is, therefore, of great importance both to the work and the workers to consider what may be learned from such experience as has been collected up to now. Engineers have not forgotten that discharged soldiers as a class did not prove satisfactory when it was sought to introduce them into industry at the end of the Boer War. Some of those who have been introduced lately have undoubtedly done better; but evidence from all parts of the country concurs in showing that, as a whole, the services of discharged service men have not been as successful in the shops as it had been hoped they would be.

Industrial Training

It is best to admit the fact plainly, because beyond any doubt a remedy has to be found for it. Whatever circumstances may impede the satisfactory amalgamation of the fraction of the armies now returning with the industries that should receive them will apply no less to the great bulk when they return at the end of the war. If the disappointments and difficulties that are now met with are glossed over or ignored, they will be left to impede much larger operations later on. If they are faced plainly and intelligently, not only may a solution be found for those for whom it is wanted at present, but their more numerous comrades may benefit by it later on.

The complaints that are received do not seem for the most part to show that discharged service men do not find any special difficulty in acquiring the necessary mechanical skill. One of the results demonstrated by experience of war manufacturing has been the extraordinary rapidity with which women can acquire a useful amount of skill—an amount insufficient. indeed, to constitute a skilled all-round tradesman, but emply sufficient to do what is required in a very large part of a properly subdivided manufacture. This experience is getting more and more a matter of common knowledge, though even now it is far from being recognized as widely as it might be. As yet, however, it does not appear to have been applied very completely in the introduction of discharged service men into industry. It has perhaps not been recognized so generally that there is no necessary reason why women should be more amenable to the intensive training by which these results are produced than men would be if they were trained in this way, and not left to the happy-go-lucky methods of trial and error by which lads pick up their trades in workshops.

There is accordingly no reason at all why discharged service men should not rapidly—that is to say, in anything from a month to two, three, or six months, according to the complexity of the craft that they are set to acquire—reach a standard of skill that is fully equal to what would be required of them in a well-organized factory. On the whole, experience seems to show that when they have ben properly trained they give fully as good results as women—results that are quite up to anything that a shop can require. What seems to be more generally lacking is the discipline of industrial life—the habit of keeping time, sticking to a job, and accepting industrial work as a contending vocation.

Factory Life

Nothing can be less surprising than this result. A soldier's life is regulated by discipline; but whether he is fighting or in reserve the discipline is entirely different from that by which men are made contented and efficient in industrial life. When a soldier is in the front lines some forms of routine discipline are greatly relaxed. The life is an alternation. It includes epochs of the severest strain, in which all circumstances combine to force men for an evident common purpose into the attitude their chiefs desire. In the intervals between these epochs of strain are periods of inevitable monotony, during which discipline, though inexorable in essential particulars, occupies a relatively small part of a man's attention. When he is in reserve a well proved and judicious artificial discipline engages practically the whole of his time; but this discipline is so shaped as not only to keep him busy but to keep him interested and amused. It would in any case be out of place for civilians to criticize methods of military discipline; but it is permissible to refer to the fact, now practcally of common knowledge among all who have followed the fortunes of men at the front with any intelligent interest, that the virtue of this apparently artificial discipline has been verified by the most conspicuous success.

When a man comes into a works discipline is no less necessary for the purpose there in view than it is in the army, but both the purpose and the methods are different. The sanction of extreme danger to a corporate body, of which each man is a member, no longer exists. The discipline is no greater at one time than another, but must extend uniformly throughout the day and the year if the work is to be done efficiently. To those who have found a technical interest in their work it may not be monotonous, but those who have not are left for the most part to get contented with their new life as best they can. They are introduced into this new situation fresh from the very different life they had led, conscious that they at least have deserved well of their country, disposed perhaps to expect a special consideration and a softening of their job not permitted by works conditions. What can be more natural than that a considerable proportion of them should become discontented? And what contenting result can be hoped for from discontented men, particularly when the ground of their discontent is a sense, whether well founded or not, that they are being treated with less than justice or with ingratitude?

The Need for Interest

It is idle for manufacturers to imagine that difficulties such as these will right themselves, and still less is it either wise or fair that the returned soldier should be pitchforked into industry to accommodate himself to the conditions of factory life as best he can, and to take the consequence in the form of exclusion if he should fail to do so, leaving out of account altogether considerations of public duty, of which nevertheless engineers are fully as sensible as any other body of men. Again, to leave soldiers to accommodate themselves to works life if they can, or to take themselves off if they cannot, would not only be unfair to the men, but would deprive industry of what should be a valuable means of production. It is more prudent as well as more decent to consider by what means military training has got such brilliant results out of the same men as are found unsatisfactory in industrial life; and when military methods are contrasted with those of industry, the chief difference will as a rule be found to lie on one hand in the absence of corporate spirit by which men should be attached to their works, and on the other hand, in the absence of means for keeping men interested and amused, which are an essential part of the discipline of military life for soldiers not actually engaged in fighting. It may be said that to attend to such matters is outside the scope of manufacturing—that either it is the business of philanthropists, or that men should be able to attend to such matters for themselves. It is needless to discuss whether this contention has any merits. The question has to be settled by much more practical considerations. Those who take the trouble to apply the arts that underlie military training to the care of men engaged in industry will have a body of co-operating workers, and given good management, such a body will be more efficient than groups of men who are not so treated. The works, therefore, that adopt these methods will have an advantage over those who do not; and in times that are coming no works can afford to dispense with any such advantage.

Position of Employers

Civil industry would, of course, fail if it aspired to the methods of control that are used by military authorities. Not only would such methods be unacceptable to workers, but it is more than doubtful whether, even if they were accepted, they would prove efficient for civil purposes. Where the military example should serve as an object lesson to employers is in the care that it takes to keep men interested, and in the extent to which it can count on their corporate spirit. The first condition for a man being interested in his work is that he shall know the difference between doing it right and doing it wrong. Where there is any chance that the work to which a discharged soldier is to be put may be done wrong, it is asking for trouble to put him straight to it among a body of men who are doing it right, and trust to luck that he will pick up the knack. Sometimes he may do so; sometimes his new mates may help him; but often, as repeated experience has shown, the men with whom he may fall into relations will not be those who are the keenest on doing the work right, and his attention will be attracted more to the inconveniences with which he has to put up than to the initiative in marked advanced of selling work which he is conscious of doing only indifferently.

The first condition, that discharged soldiers should have a reasonable assurance of being interested in their work, is that, either in the works itself or in some preliminary training school or instructional factory, they shall be grouped with other men in like position and be shown how to do the work right and how to extract from it all the technical interest that it can yield. While a man is learning thus he will need more personal attention and encouragement than the ordinary routine of most works can spare. At the same time some influence beyond what an ordinary works atmosphere will exercise on a newcomer will be required to help him into habits of punctuality and continuous attention. Some works who adopt no such means find that a majority of the discharged soldiers whom they take on do not stop at their work, but that those who do stick to it for three months remain permanently and do well. Probably a much higher proportion could be trusted to see the thing through if they had a reasonable introduction or re-education in industrial life, given under conditions that include the necessary personal attention and encouragement.

It must, however, be remembered that men vary individually in the work which suits them and which they can do best. A man himself cannot be certain that he will select his occupation suitably, when he has yet to learn and become accustomed to its details; and though experience may do much to cultivate in an instructor the intuition that selects correctly the work for each man, the wisest instructor cannot always be right. The latitude that can wisely be shown discharged soldiers, if the best use is to be made of their services in their own interest and that of industry, should therefore include the choice of a second class of work, should the first not have been suitably chosen.

Team Work

When, however, the initial difficulties have been overcome there remains a wide scope for trying to induce into civil industry the corporate co-operation that is found in military units. What is wanted is not that men should learn either to be eloquent themselves on the rights or wrongs of classes, or—the more frequent case—to sit under other men whose chief stock-in-trade lies in such eloquence, but that they shall be actively practising co-operation as charity should be practised, beginning with their own industrial homes. The purpose of a works is co-operation to a useful industrial end. The more fully that end is attained the better the works, and in any well-managed works the better for each worker. The common experience shows that that co-operation is never so keen and active as when it is promoted by immediate competition. In those works that are large enough to have separate units a wide field is open for stimulating interest by promoting competition between shops or other groups of men within the works.

Two-Ton Electric Furnace Makes Alloys

Heroult Furnace Used For Non-ferrous Alloys—Description of Plant and Equipment

An electric furnace, whose main product is nichrome, the well-known high-temperature resisting alloy, has recently been installed at the plant of the Driver-Harris Co., Harrison, N.J. The furnace is of special interest because of its electrical equipment, which is an excellent example of modern practice. Alloys of various characters are also manufactured by the furnace. It is of the Heroult Arc type, featured with automatic regulation, and has a capacity of two tons.

The amount of power taken at the start of the heat is small, but as the resistance of the furnace circuit decreases, owing to the heating up of the electrodes and the consolidation of the charge, the power consumption rapidly increases until stable conditions are reached. The average amount of power consumed is then held practically constant by the automatic regulator, with the exception of a slight continuous increase, due probably to a corresponding decrease in the resistance of the furnace circuit.

There is, however, no uniformity in the actual power consumption. As the charge melts down, pieces of metal fall between the electrodes and establish short circuits. For the most part these short circuits are only momentary as the fragments causing them are promptly melted down, but occasionally they persist, and then the automatic regulator draws up the electrodes until they are clear. This process sometimes breaks the arc and then there is a sudden decrease in the power consumption until the regulator brings the electrodes down again and re-establishes the arc. As would be expected steel alloys show more of these irregularities than the softer nichrome.

Towards the end of the run there is a marked change in the power consumption when the metal is given a special treatment before pouring. In the case of the nickel steel a higher temperature was necessary, perhaps to lower the carbon contents, while with nichrome the temperature was lowered. The temperature of the furnace averages about 2,200° Fahr.

The high momentary overloads are characteristic of electric furnace work and make it very different from ordinary power service. They must be taken into account in designing the electrical equipment for the furnace, and some of the apparatus must be specially designed to withstand them, as shown in the following description of the Driver-Harris installation.

Power for this furnace is furnished in the form of two-phase, 60-cycle, 2,200-volt current from the lines of the Public Service Electric Co. In the high tension lines are a disconnecting switch and an oil circuit breaker. This latter is used to control the circuit. It can be operated manually and is also provided with low-voltage and overload protection. In order to prevent its operation on momentary overloads, the overload trip is controlled by relays with definite inverse time-limit action. The high tension apparatus and the transformers are contained in a brick compartment behind the furnace.

There are two 400-kva., 2,200 110-volt transformers of the oil-insulated self-cooled type. They are Scott-connected so that they change the high-voltage two-phase current into low-voltage three-phase current, one phase for each of the three electrodes of the furnace.

Special construction is necessary to withstand the overloads. These overloads are of such short duration that their heating effect is negligible, but they tend to force the coils apart. Hence the coils are very firmly braced and are in fact capable of withstanding momentary overloads fifteen times greater than the normal load.

The reactance of these transformers is about double that of ordinary power transformers of the same size. This re-

actance together with that developed in the low tension leads (which are made as short as possible in order to keep this factor low) prevents the current flowing through the furnace from exceeding five or six times normal values even on dead short circuits. The voltage regulation is from 106 volts on no load to about 100 volts on full load, and the power factor is from 85 to 90 per cent.

One of the most interesting features of the equipment is the Thury regulator, which automatically maintains an approximately constant current at the furnace electrodes. Without this device the current consumption would vary erratically even if an operator were constantly endeavoring to correct the variations. It therefore saves labor and current, reduces to a minimum the time required to prepare a charge, and by providing uniform conditions keeps the quality of the product uniform.

Each furnace electrode has a separate regulating mechanism and a raising and lowering motor. The regulator can be set for any desired current value, and when this value is exceeded each regulating mchanism closes a contact momentarily, which causes the motors to raise the electrodes slightly. The contacts continue to close at brief intervals until the electrodes are drawn up high enough to reduce the current to the predetermined value, the intermittent action being employed to prevent the electrodes from being raised too high and thus causing an unstable condition. When the current falls below the predetermined value the electrodes are lowered in a similar manner. The regulator itself is controlled by a solenoid energized by means of current from series transformers in the main high-tension circuit. Damping devices prevent the regulator from acting on overloads that immediately correct themselves.

In addition to the automatic device, each electrode motor has a drum controller for manual operation.

The electrode motors are direct-current machines, because alternating current motors cannot be controlled with sufficient delicacy. The operating current is obtained from a 4½ kw. motor-generator set located in the transformer compartment. The motors are 2 h.p. capacity and are totally enclosed. They are provided with grease-cup lubrication instead of the ordinary ring-oiling sys-

tem so that the lubrication is not interfered with when the furnace is tilted for pouring.

An instrument board is located beside the regulators and carries the following apparatus: A kilowatt meter; a volt meter; a power factor meter; an ammeter for each phase; a graphic wattmeter; a plug switch for reading the voltage of each phase, both across the arc and across the low-tension leads outside the furnace; the operating handle of the high-tension circuit breaker; the inverse-time-element relays for the circuit breaker, and an integrating kilowatt-hour meter.

On the other side of the regulator is mounted a small panel carrying the switches and meters for the motor-generator set, below which is the motor auto-starter.

When the charge is finished the whole furnace is tilted bodily for pouring. This tilting is effected by an 11-h.p. alternating-current slipring motor located in a pit beneath the furnace and geared to the tilting mechanism. It is controlled by a drum controller by the side of the furnace.

The regulating, tilting and control equipment was supplied by the Westinghouse Co.

The Montreal General Tool Co., of Montreal, expect to secure a contract for one hundred marine pumps, the value of which will approximate $300,000.

STOKER MANUFACTURERS' ASSOCIATION

At a meeting in Cleveland on August 1, 1918, an association was formed of the stoker manufacturers of the United States. The principal reason for getting together was to place at the disposal of the government the entire facilities of the stoker industry to the end that everything possible might be done to help out in the national emergency. Even after the war, however, it is expected that great benefit will be obtained by the association members in the discussion of subjects of interest and value to the stoker industry; in the advancement and improvement of that industry; in the standardization of stoker manufacture and application, and in the promotion of a spirit of co-operation among its members for improved production and increased application of stokers. Practically all of the builders of mechanical stokers are included as charter members of the association.

At the first meeting the following officers and executive committee were elected: President, P. Albert Poppenhusen, Chicago, Ill.; vice-president, S. L. Nicholson, E. Pittsburg, Pa.; secretary-treasurer, Fred H. Daniels, Worcester, Mass.; William F. Sauter, Philadelphia, Pa.; W. H. Rea, Detroit, Mich.

The Stoker Manufacturers' Association has been informed that it has been formally elected to membership in the Chamber of Commerce of the United States. A national councillor will be appointed by the association to represent it in the National Chamber, and through this national councillor the association will have an opportunity of expressing itself on national questions under discussion by the federal authorities.

The association, through its War Service Committee, has tendered to the federal government the entire resources and service of its members, and the committee is working with the Fuel Administration and the War Industries Board for the conservation of fuel, labor and raw materials. The association is prepared to do any and everything which may be necessary to prove that American business is ready to back up the government until victory is assured.

OBITUARY

Mr. Frank Davey, superintendent of the Lyall Shipyards, Vancouver, died last week after a short illness. Mr. Davey, who was born in Hamilton, O., went to the coast ten years ago and entered the employ of Mr. Andrew Wallace, who was then starting the Vancouver yards. He remained with the Wallace Company until the Bewicke Avenue yard was transferred to the William Lyall Shipbuilding Co., when he was appointed superintendent for that firm. He held this position up to the time of his death.

Educational Value of Munitions in Canada

Mechanics Who Used to Measure an Inch Into Eight Parts For Fine Work Now on Speaking Terms With Some of the Finest Dimensions in the Trade

By J. N. ROBINSON

SHORTLY after war broke out it was suggested that Canadian factories manufacture munitions. The idea was scouted by most of the manufacturers. They claimed it was an impossibility to handle this fine work with the class of labor and machinery obtainable in Canada. However, some few were bolder, and with the advice of the Imperial authorities, and with the wonderful driving power and enthusiasm of the Minister of Militia, Sir Sam Hughes, behind them, they embarked on the enterprise.

What their troubles and difficulties were during the year of 1915 will never be realized. But the biggest obstacles were gradually overcome and to-day Canada's shell plants compare favorably with any others in the world.

We have re-built old machinery to our needs, and we have built new. But greatest of all we have trained men and women to handle the fine work necessary in making shells. It ordinarily takes from three to five or seven years for a man to work out his apprenticeship in any of the mechanical trades. But here in Canada we had to take men who hardly knew there was a measurement smaller than one-eighth of an inch, and women who measured things by the yard or by the length of their fingers and teach them to work to limits of two or three thousandths of an inch or even finer. And it had to be done in a hurry. England needed the shells and Germany would not wait until we learned how to make them.

True, we had in Canada a large number of splendid mechanics who needed little or no training to enable them to handle this fine work. But a great many of them enlisted and many more went to England to work in the munition plants there. This left us sadly handicapped at a time when we were in dire need of the best mechanical skill obtainable.

That we did succeed is largely due to the untiring energies of the manufacturers and too much credit cannot be given them.

To-day we have many thousands of men and women successfully handling this very finest class of work. They learned under the stress of the moment and because it was absolutely necessary for them to learn, for their work at that time was indispensable to England.

And what they have learned they will not forget. After the war if they do go back to their old trades they will unconsciously do better, finer work. The need for this has been drilled into them for nearly four years. They will be better workmen and will command better wages.

But They Learned It

A typical case of this follows. Early in 1915 a company in a small town near Toronto obtained a contract for 4.5-inch brass nose sockets. Their regular line of work was on iron castings. They had a splendid organization and many loyal men. But when it came to getting down to fine work they failed badly. Government inspectors were sent to the plant with orders to give the management all the help possible in the manufacture of the sockets.

One of the inspectors in helping a man to set up a machine, made the suggestion that if a certain measurement on a roughing cut was made one-sixteenth of an inch smaller, it would make the succeeding operation easier and quicker.

The man opened his mouth in blank amazement and stared at the inspector. Then drawing a blacksmith's scale out of the leg pocket of his overalls he examined it carefully, glancing scornfully at the inspector from time to time. Finally he folded up the rule and put it away, saying, "Say, boss, when you start to talk about sixteenths of an inch around this shop you are in the wrong boat. If you talk of eighths I might be able to follow you. But nothing less than that goes around here."

A few days ago this same inspector met the workman —Jones, we'll call him—on the street. He didn't know Jones. Jones was neatly dressed and appeared prosperous, and in general looked more of a success than he did three years ago. Jones had to tell his name, for the inspector could not place him as the man who did not know what a sixteenth of an inch looked like.

It seems that Jones is now working in a factory making shell gauges. He has learned his lesson. He now not only knows what a sixteenth of an inch is, but is on familiar speaking terms with ten-thousandths of an inch, pitch diameters, root diameters, thread micrometers, vernier scales and all the terms and instruments used in fine mechanical work.

So "it's an ill wind that blows nobody good," and the above case is typical of thousands of others. In fact the education value of the munitions industry in Canada can never be indicated in dollars and cents. But the workmen and women who have learned will be better workmen and women and better citizens hereafter because they are more efficient. And in these days of manufacturing competition it is efficiency that counts.

But Times Change

I USED to think I'd like to have a job of bein' a king, or else an emperor or duke or some such hefty thing, to have a crown stuck on my dome and set upon a throne, and havin' fifty thousand folks a-dustin' round your home.

To say unto this man, get out, to that chap, come in, to see them hustle off the porch and 'op about like sin.

To always have a dollar bill to blow just when I please, and not to hear my creditors line up and snort and wheeze. To have ten pairs of boots to wear and sixteen suits of clothes, by heck, that gent would have no frets, no troubles and no woes.

But just the other day the folks what dwell about Berlin, they pulled a trick that worried me and got beneath my skin. They went unto the Kaiser's place, they pounded on the door, and walked with muddy, ob'-nailed boots upon his parlor floor, and took the crown from off his brow and gave it to some jay, who used to wear a homespun gown and dine on bread and hay.

And then they turned again to him what ruled the German land, and they had blood within their eye and muscle in their hand, and said: "Now, Bill, hoist out of this, and move your wife from here, for after this you'll drift and earn your wieners and your beer."

I'd rather have some lowly job, where I could show my worth, where I could take a pick and gouge some holes into the earth. Where I could hear the boss come 'round and say, "You are a bird, I'll make you boss some day, you jay, of all the bloomin' herd. You'll rise to be a dandy here, the banks will court you soon, I'll give unto you ten bucks more and holidays in June."

No, this here job of kingin' and emperorin' over folks, and tryin' to stand in sideways with all the warrin' blokes, it ain't just what it used to be, I'd rather be uncrowned, the way they're grabbin' things and tossin' them around. —ARK.

WHAT OUR READERS THINK AND DO

Views and Opinions Regarding Industrial Developments, Factory Administration and Allied Topics Relating to Engineering Activity

MAKING A RECORDING STEAM CONSUMPTION METER

By T. H. FENNER, Associate Editor.

THE necessity often arises in plant and factory operation to determine the amount of steam consumed by a particular apparatus. This may be occasioned by the requirements of the cost accounting department, or by the desire to compare two different ways of operating the same unit, or the relative merits of two different appliances for the same purpose. For all these purposes, accuracy is the essence of the contract, while the question of obtaining accuracy with small expense is also important.

Methods of Measuring Water

If there are suitable tilting traps on the premises, to which a counter can be attached, registering the number of times the trap discharges in a certain time, then the volume of the trap being known fairly accurate results can be obtained. However, there is always room for inaccuracies to creep in, through leakage from glands, valves, etc. If all working parts are perfectly free to move, the trap will be sensitive, and open and shut promptly, while if the gland packings are at all hard, or unduly tight, the trap is slow to open and discharge and steam is blown through for a moment after the condensation has been removed. Errors like these are small in themselves, but multiplied by a large number of operations extending over days, they make a respectable total, and render valueless any test that does not take them into account. An ordinary water meter may be used, but these are by no means to be depended on. If a Venturi meter can be connected up to the return pipe, it is possibly the best means of securing the consumption, but a large number of plants do not possess these instruments, and where they are installed they are usually connected to the boiler feed, and are not easily moved.

Needed a Meter

The writer had occasion some time back to determine the steam consumption on a number of different kilns, used for baking Japan, varnish. etc., also lumber drying kilns. As the results were to establish the cost of production of various parts, accuracy was necessary, while at the same time it was not desired to go to much expense in securing the figures. Under these circumstances a search around the plant was made for suitable equipment. There were a variety of traps on the premises but none on which much dependence could be placed for a particular job of this kind, so they were eliminated from the list of possibilities. However, in looking around a store house of obsolete or unused machines, several steel tanks that had been used in the plating room, were discovered, and these suggested the idea of making our own measuring appliance, which was at once acted on, the result being a very serviceable instrument, at practically no cost.

HOME-MADE WATER METER

How It Was Made

The tank, as shown in the cut was mounted on skids, and kept about 18-inches off the floor. This was to give room for the discharge pipe to come below the bottom of the tank. The general arrangement can be followed easily by referring to the cut, and the action was as follows. The condensation was led into the tank from the kiln to be tested by a half-inch pipe. A 2-inch nipple with a long thread was screwed into the side of the tank near the top, and a union put on inside the tank, to connect the suction leg of the siphon pipe. The down leg of siphon was connected to nipple through the elbow outside the tank as shown ,and the pipe carried down low enough to give a good discharging head. On the end of the discharge pipe a clock valve was fastened by a hinge, and on the opposite side to the hinge a lug was carried out, to which was fastened a wire, the other end being fastened to a beam in the ceiling, and a light spring conneeted between.

This valve and spring were the key to the whole affair, and some considerable experimenting had to be made before the correct strength of spring was arrived at. This spring had to have just enough tension to balance the column of water in the siphon pipe, so that the instant the water rose above the top of the pipe, the valve would open. This would start the siphon, and the velocity of the escaping water held the valve open till the water was emptied down eo the level of the bottom of suction pipe. The spring would then close the valve, and the tank fill again. Here then, we had a definite quantity of water discharged, and all that was wanted was a means of recording the number of times the tank was filled and discharged in a definite period, and make one necessary correction. This correction was the quantity of water flowing into the tank from the return pipe while the siphon was discharging. This was merely a matter of placing a T on the return pipe, with a valve outside the tank. A pail was placed under this, and the tank watched carefully, and as soon as the siphon opened, the valve on the return pipe was opened and the water ran out into the pail instead of the tank. As soon as the tank was emptied, the valve was closed and the water in the pail weighed carefully. This weight had to be added to the weight of water discharging from the tank, to make it correct.

The Recording Chart

For recording the number of times discharged, a chart, registering automatically was required. This was secured by purchasing for 75 cents an ordinary domestic alarm clock. The fingers and dial were removed, and a tin dial soldered onto the spindle of the hour hand. Four small cleats were made on the new dial to hold a paper chart. A flat piece of wood, 1-inch thick by 6-inch. square formed a float into which was fastened a piece of ¼-inch round iron, which passed through a guide fixed on the flanged edge of the tank. A cross beam of wood was connected to the top end of this and this was supported on a fulcrum about two-thirds of its length away from the float rod. The other end carried a vertical rod, through which was passed the pencil. A stop was placed on the float rod, to hold the float up when the water dropped below a certain level. This level was adjusted to give just enough upward travel to the float when tank was filling, to make a mark of 1½-inch. long on the chart. The charts were placed on the dial at 7.00 a.m. and 7.00 p.m. and thus a continuous 12 hours record appeared on each chart The position of the clock is shown on drawing. In the actual layout the clock was enclosed in a wooden box, to protect it from steam, and dirt in the air. The valve on the bottom of siphon pipe was made of two pieces of galvanized iron No. 16 gauge, one soldered to the other. The top piece was of just sufficient diameter to enter the pipe neatly, while the bottom piece was made to the outside diameter of the pipe, and two lugs made on it, one for the hinge the other for the wire. A piece of good 1-16 wire wove insertion was made to fit the end of the pipe, to form a joint, and fastened onto the valve to begin with by shellac. Otherwise, the rush of the water would have washed it off. Later on this insertion joint was replaced by a ring of square rubber, ¼-inch wide by ⅛-inch thick. This was more satisfactory. Later on two more tanks and clocks were added, to enable three different tests to be made at once. This method resulted in accurate figures being furnished, and the only new material was the three clocks costing $2.25. The pipe and fittings were all on hand, and the labor amounted to probably another $2.

CUTTING LUBRICANTS THEORY AND PRACTICE

A MEMORANDUM on cutting lubricants and cooling liquids issued as Bulletin No. 2 by the Department of Scientific and Industrial Research, England was prepared in connection with a survey of the field for research or lubricants and lubrication. While the bulletin is not claimed to contain new knowledge, it is published in the belief that it furnishes a large amount of useful information which will be new to many users of cutting lubricants and likely to increase the efficiency of production in operations concerned with the cutting of metals.

The materials discussed in the first part of the memorandum, which is by Mr. T. C. Thomsen, are classified as soluble oils, which are oily liquids that form emulsions when mixed with water; soluble compounds or cutting compounds, which are greasy pastes that form emulsions when mixed with water; cutting emulsions, formed by mixing soluble oils or soluble compounds with water; and cutting oils, such as lard oil, rape oil, mineral oils, or mixtures of such oils, free from water and soap, which ordinarily do not form emulsions with water.

Characteristics and Preparation

The mineral oils best suited for use as cutting lubricants, either alone or mixed with animal or vegetable oil, are preferably of pale color and low viscosity, ranging from 100 to 200 seconds Redwood at 100° Fahr.. those of lower viscosity being used for high-speed conditions, and those of higher viscosity for slow speeds. Tinged lard oil, containing as much as 10 or 15 per cent. of free fatty acid, is the animal oil most frequently used either alone or in admixture; prime lard oil, which is almost free from acid, is more expensive, but is less inclined to gum under severe conditions of heavy cut and high speed. Wherever possible a mixture of lard oil and low cold test mineral oil is to be preferred on account of greater fluidity in the cold. Cottonseed oil oxidizes more readily than rape oil, and should not be used for cutting lubricants that are to be employed in a circulation system. Animal oils are not so easily oxidized in circulation systems as are vegetable oils, and lard oil produces deposits in such systems under severe operative conditions only when the percentage of free acid exceeds, say, 10 per cent. Cutting oils are nearly always used "straight," i.e., without admixture of oils; some of them containing at least 5 per cent. of free fatty acid and preferably over 20 per cent. of saponifiable (animal or vegetable) oil, may be used either straight or in the form of cutting emulsions. They will emulsify with water to which the requisite amount of alkali (soda ash, borax, etc.) has been added.

Soluble oils are prepared by dissolving a soap (usually less than 20 per cent.) in a mixture of mineral oil (usually less than 70 per cent.) and saponifiable oil (usually more than 15 per cent.). The oils used for making the soap are either animal or vegetable (lard oil or other olein from animal fat, whale oil, wool grease, castor oil, sulphonated castor oil, rape oil, cottonseed oil, resin, etc.), and are saponified with caustic soda or potash. In some cases a small percentage of alcohol or ammonia is employed to promote the formation of the emulsion. Soluble compounds are made on similar lines, except that they contain 10 to 50 per cent. of water and are in a semi-solid and semi-emulsified condition. They are not so easily mixed with water as soluble oils, which therefore are usually preferred.

Purposes of Use

Cutting lubricants and cooling liquids are used for the purposes of cooling, lubricating, producing smooth finish, washing away chips and protecting the finished product from rust or corrosion.

The importance of properly cooling the product, particularly under high-speed conditions and with materials such as aluminum which have a high coefficient of expansion, lies in the fact that the material is warmed by the heat developed during machining, and contracts on cooling, its dimensions then differing from the measurements taken during machining. Excessive heating of the tool causes the cutting edge to wear rapidly; in a tool of large section the heat is more rapidly conducted away than in one small section. Efficient cooling of the tool edge increases output; with high-speed steel the gain in cutting speed on steel and wrought iron is from 30 to 40 per cent., and on cast iron from 16 to 20 per cent. Efficient cooling of the shavings on the side not in contact with the tool is particularly important in tough material, helping to reduce the friction produced by the shavings rubbing against the nose of the tool. Lubrication is of little importance where the manufactured article is made of brittle material, but is very important where the metal is tough and is removed as spiral shavings which grind their way over the face of the tool. The heavier the cut the greater the necessity for lubricating the nose of the tool.

When the requirements of cooling and lubrication are satisfied the finish will be good. Cutting oils of great oiliness are required for a very smooth finish, and for this purpose some engineers find vegetable oils, such as rape or cotton seed, preferable to either mineral or animal oils. Dies, taps, reamers and form tools have a longer lift when used on tough steel if a cutting oil is employed in place of an emulsion prepared from a compound or soluble oil. For finish boring, rifling, etc., a mixture of 1 part of castor oil to 3 parts of mineral cleaning oil (gravity about 860-890) has been used with good results; the addition of an equal volume of turpentine substitute (white spirit) causes perfect solution to take place and is said to be advantageous for finish turning on guns and hard material.

The washing away of chips is often quite an important function of the cutting lubricant or cooling liquid, particularly in cases of deep drilling and in most milling operations. In boring deep holes, gun-tubes, etc., a solution of 50 lb. of sodium carbonate and 25 lb. of soft soap in 200 gallons of water has given very satisfactory results. If the cutting emulsion is too weak it will not carry away with it the minute particles of metal and scale, which may prove detrimental to the machine tool.

Good cutting oils used straight will not cause rusting, but those containing fixed (animal or vegetable) oils, such as lard oil with a large percentage of free fatty acid, will give rise to verdigris on brass. Vegetable oils such as rape, with a small percentage of free acid, do not produce verdigris unless they are rancid. Cutting emulsions made up from cutting compounds or soluble oils and water cause rusting if they are used too weak or if they contain acid. Water containing sodium chloride is most destructive to emulsions and must not be used, nor must hard water on account of the precipitate caused by the calcium and magnesium salts in it. Emulsions of oil and water are not stable in the presence of even minute quantities of acid; to a limited extent they can be reformed by neutralizing the acid with ammonia, but excess of alkali may facilitate corrosion.

Factors in Selection

Low speeds and shallow cuts require little cooling and lubrication. Low speeds and heavy cuts demand a lubricant of great oiliness, particularly if the material is tough. High speeds and shallow cuts demand a cutting medium with great cooling properties; hence emulsions are favored and should be used if the speeds are particularly high. Turpentine substitute is a satisfactory lubricant for aluminum, but being inflammable must be used with care. A mixture of paraffin oil and lard or other cutting oil for high speed work on aluminum is also dangerous, and has led to several fires. Cutting emulsions which possess the necessary cooling properties, and are not inflammable, are to be preferred.

Cutting emulsions are nearly always used for brittle material, and frequently for tough material if the speeds are high and the cuts light; when the material is tough and the cut heavy it is necessary to employ cutting lubricants used straight and containing 10 to 50 per cent. of animal or vegetable oils, or consisting entirely of such oils. Emulsions, in some cases, have been found to form a deposit on the working parts of automatic screw-cutting machines; this may be avoided by using straight oils, but emulsions should be adopted wherever possible, in view of the present scarcity of oil. The amount of soluble oil or soluble compound used in preparing the cutting emulsion varies from 2½ to 20 per cent.; the richer mixtures are used for severe conditions, and the weaker for light duty or for materials like brass and aluminum, where there is no danger of rusting.

The cutting lubricant may be applied by hand by a drop-feed system, or by some system employing gravity or pumping. In large machine shops the cutting oil is sometimes circulated in pipes throughout the works, returning through other pipes to a central tank; group systems with central tanks are excellent where one mixture is used for all the machines on the circuit. The return pipes should be large and arranged for easy access for cleaning; isolating valves should be employed to sectionalize the system when large; efficient strainers should be fitted on all return pipes and pump sections, and should be cleaned daily. Tanks, as a rule, should be cleaned out every four weeks, and return pipes every four months. Any scum formed should be skimmed off the tanks daily. It must be remembered that the oil or emulsion, in any system in which it is circulated over and over again, is exposed to the admixture of dust and dirt from the machine shop and to the oxidizing influence of air. The suction of any pumps that are employed should always be covered to prevent air from being drawn in, since aeration of the oil or emulsion has a strong oxidizing effect upon it.

Effects on Health

In the concluding part of the memorandum, Dr. J. C. Bridge deals with skin diseases produced by lubricants. He describes oil rashes as being, generally speaking, of two kinds—one due to the plugging of the small glands at the root of the hairs on the arms and legs of workers, and the other to mechanical injury to the skin produced by metallic particles suspended in the cutting lubricant. Primarily the first is purely mechanical. The plugging of the minute openings of the glands by the mixture of oil and dirt sets up inflammation round the hairs, and this may lead to suppuration or abscess formation. Injury from suspended particles occurs chiefly on the hands, where two surfaces are rubbed together, e.g., the skin between the fingers. Injury to the skin may also be produced by wiping the hands or arms with a cloth or rag when they are coated with a film in which metallic particles are suspended. Such injury permits the entry of germs and causes septic infection.

Methods of prevention include cleanness of the workers of the lubricant and of the machines. Washing accommodation must be on a liberal scale, and hot water, soap, and scrubbing brushes are essential. Workers should be instructed not to wipe their hands on rags before washing and to avoid washing their hands in the cutting compounds. Either soap, which dissolves oil, has been found useful in preventing inflammation of the hair follicles, and dusting the arms with a powder containing equal parts of starch and zinc oxide before starting work prevents the action of the oil on the skin.

In handling of the constituents of the lubricant before blending care must be taken that they have not undergone changes such as the formation of free fatty acid. Constant removal of metal particles is necessary; filtration, such as is provided on the machines, and centrifugal action are insufficient. When straight oils are used their viscosity can be diminished by heat sufficiently to allow the particles to sink without affecting the lubricating value, and this operation completely removes the particles. Where this procedure is impossible constant change and renewal of the lubricants are necessary. Frequent cleaning of the machines, with removal of all old lubricant from their parts, is essential.

Various antiseptics, carbolic acid (1 to 2 per cent.) being the most common, have been added to the lubricant to prevent rashes, and in the case of cutting emulsions disinfectants soluble in water have been used to the extent of 0.5 per cent. for the same purpose. The results, however, have not been altogether satisfactory, and the method cannot be relied on to prevent skin rashes. Heating the cutting oil to 300 ° Fahr. for a short period, with the object both of sterilizing it and of increasing its antiseptic or germicidal action, has been suggested, laboratory experiments in America having shown that oil which has been heated by use possesses rather marked germicidal effects. Apparently heating new oil does bestow germicidal powers on it; the actual temperature required has not been determined but is above 125° C.

Workers whose hands have become the seat of septic infection should not be allowed to work on machines as they are liable to infect the oil with germs and so infect others. As a general rule frequent washing with soap and hot water is sufficient to bring about rapid cure of folliculitis produced by plugging of the glands. Subsequently the skin may be dusted with zinc oxide and starch powder, and where this has been insufficient a mild antiseptic applied on lint has relieved the irritation and given good results. Septic infection of the skin due to cuts should be treated on general principles with suitable antiseptic dressings.

DEVELOPMENTS IN SHOP EQUIPMENT

Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.

NEW FULFLO PUMP

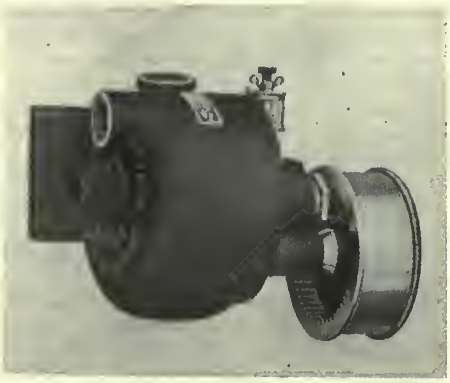
OWING to a demand from manufacturers of small grinders, drill presses, milling machines, hack saws, etc., for a smaller size "Fulflo" pump, the Fulflo Pump Co., Blanchester, O., have developed the small direct driven pump illustrated herewith. This pump is provided with a ⅜-inch intake and outlet, and has a capacity for pumping up to 5 gallons per minute when compound or water solutions are used, and 3 gallons per minute when mineral lard or oils of like viscosity are handled. Like all of the "Fulflo" pump designs, this type is centrifugal in action, and it may be placed above the level of the liquid, and absolutely retain its prime under all conditions without the aid of valves or other mechanical means. There is but one internal working part—the impellor—that does not depend upon any contact fits for pumping efficiency; consequently it is not affected by grit, chips or other abrasive matter that is always present in the liquid being pumped. The pressure is not cumulative and therefore no relief valve or overflow piping is required, since the flow is entirely controlled by a stop cock at the outlet of the piping, which may be opened or closed at will. The pump may be permitted to run indefinitely with the stop cock closed without damaging either pump or piping.

There being no passages in the pump interior smaller than the intake and outlet obviates all possibility of clogging, and anything that can be sucked in will pass through without damage. Bearings do not come in contact with the liquid pumped, and are oiled through lubricators that are supplied with pump. The shaft of the pump is hardened and ground, made of cold rolled steel, all other parts except bearings which are bronze, are of cast iron. Pumps can be furnished of brass or bronze. The packing is of flexible metallic type, not affected by any liquid either hot or cold.

The pad for mounting is located at the bottom of the pump, but when it is desirable, an angle bracket is furnished on which the pad can be bolted; this allows the mounting to be made at either the back or the front of the pump as may be desired.

The over all dimensions are 7⅞ in. x 5 in. The pump has a greater capacity by 50 per cent. than any other type of pump manufactured for machine tool use of equal size. The driving pulley is 1½ in. in diameter; 1 in. or 1¼ in. single belt is used. The pump is built to stand speeds up to 3,500 r.p.m. Weight, complete, about 9½ lbs.

To give an idea of the capacity and flexibility of this little pump, at 2,100 r.p.m. with a 12 in. suction and a 4 ft. head lift the flow will be 3½ gallons per minute. With the same suction and the same head lift at 2,600 r.p.m. the flow will be 5 gallons per minute. With a 30 inch suction and a 10 ft. head lift, at speed of 3,000 r.p.m., the flow will be 5 gallons per minute. With a 30 inch suction and an 18 ft. head lift, at speed of 3,500 r.p.m., the flow will be 3½ gallons per minute. It will thus be seen that this pump is capable of supplying any machine tool that does not require more than 5 gallons per minute of liquid and will meet any possible condition that may be demanded at any machine shop.



NEW FULFLO PUMP

SHELL LATHES

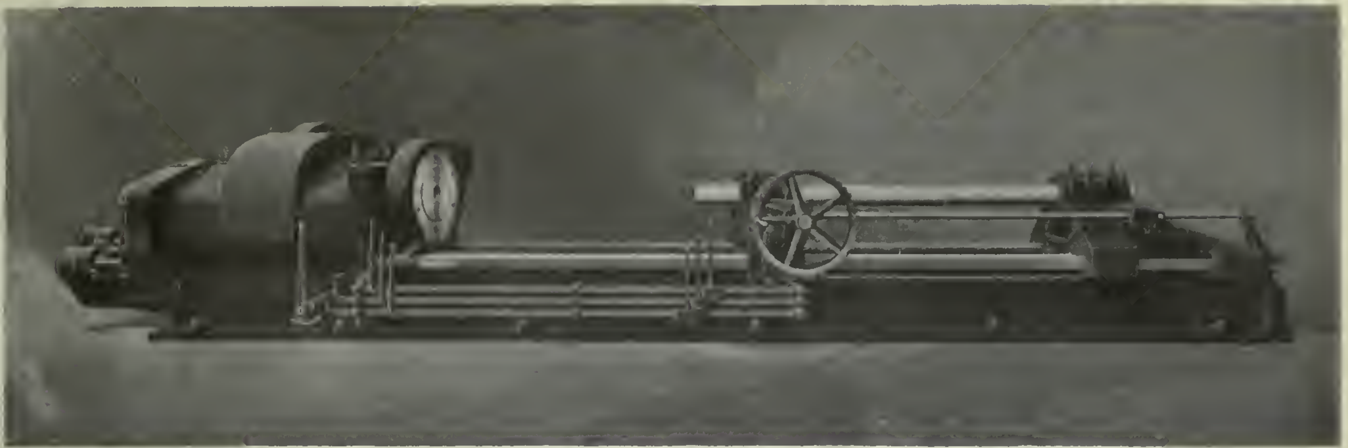
The Amalgamated Machinery Corporation, Chicago, now has nearing completion the first of 168 large lathes for turning and boring shells in the Neville Island, Pittsburgh, ordnance plant which the United States Steel Corporation is building for the Government.

The turning lathe is 29 ft. 9 in. in length over all; 5 ft., 3 in. in width, has a swing of 39 in., and at the headstock end is 6 ft., 8 in. in height. The total weight is approximately 65,000 lb. The new machines embrace several novel features apart from their massiveness. The spindle has a double drive; there are unusual and convenient means of control; the feed screw is placed in the center of the bed, instead of outside and through the apron of a carriage; there is a specially-designed method of turning the curved portion of the shell, besides other features, as will be described.

The bed and headstock are cast in one piece. The machine is belt-driven by a 12 x 16-in. pulley on the first driving shaft, the pulley being equipped with a friction clutch, thus obviating any overhead countershaft with tight and loose pulleys, or other overhead contrivances for starting and stopping the machine. The speed reduction gears are contained in the headstock, four gear shifts giving four spindle speeds with a constant speed of the first driving shaft. The gear ratios are 27.3, 31.3, 36.1 and 42 to 1.

The driving gear changes have been so proportioned that when the work is changed from shells of one size to another the cutting speed may remain unchanged. The feed change gears are easily accessible through a door at the end of the headstock. The faceplate itself is a gear, while also on the spindle, back of the front bearing, is another gear, the teeth of the two being staggered, thus distributing the application of power and averting a tendency in the spindle main bearing to wear bell-mouthed.

Because of the contour which must be given the shell, both cross slides are fitted with forming attachments that are fastened to the carriage at the back. The one which enables one tool to form the flare is a simple arm connected with a block which slides in a slot that inclines toward the axis of the shell and in the direction of the live center. More complicated, though still simple, is the arrangement for compelling the other tool to follow the proper curve to be imparted to the nose of the shell, this end being toward the dead center of the lathe. In this case, two arms radiate from a point on the slide to which they are firmly attached, forming a triangle, the two back corners of which



SHELL BORING LATHE

are attached to blocks that slide in a cam slot having its outline curved to correspond with the curve of the shell. The result is that the tool moves with a motion similar to that which it would take if it were pivoted on an arm several feet long, the tool and holder being at all times at right angles to the work, a phase of the arrangement which is considered most important as it obviates any tendency of the tool to mount the curve in steps and causes the proper cutting edge to be presented to the work at all times. The cutting edge does not change as it would if the tool were at right angles to the axis of the shell.

The carriage consists in part of what is termed a master carriage, this being in reality the base and the part that rests on the ways and that carries the nut through, which motion is imparted by the feed screw. The upper part of the carriage, including the cross slides and the apparatus for giving the proper contour to the shells, is easily changed for each size of shells.

The tailstock is of heavy design corresponding to the other parts of the lathe, and is held secure to the bed by eight 1½-in. bolts. The spindles, both live and dead, are 7 15-16 in. in diameter.

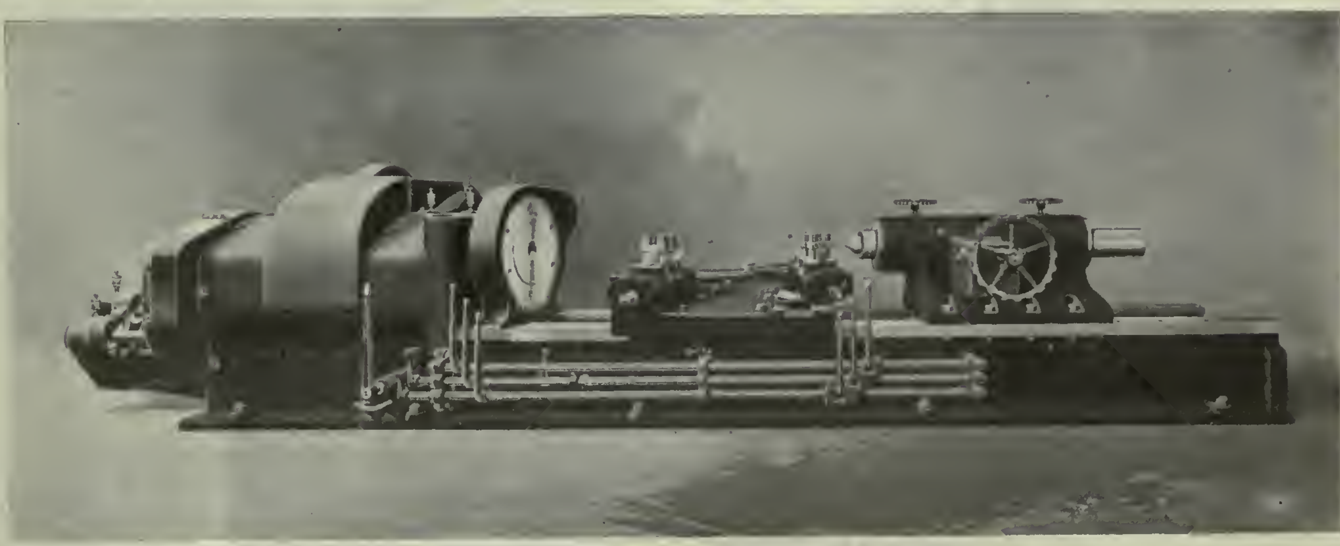
The boring lathe differs from the turning machine in that the carriage and tailstock are eliminated and replaced with the necessary equipment for holding and operating a boring bar, the end of which is bored to take a taper shank attached to a boring head carrying the cutters. The boring bar is 7 15-16 in. in diameter, and 11 ft., 6 in. long. It is supported by a rest in which it slides, and by a carriage in which it is clamped and keyed. The rest is fitted with a bushing and is moved by power, having a half nut which meshes with the feed screw beneath, and is made to move by lifting a lever.

An important feature of the boring-bar carriage is an arrangement whereby the movement of the carriage and consequently the feed of the bar can be retarded or accelerated by turning a hand-wheel on the rest, thus virtually giving the bar the advantage of hand feed when it is desired. The handwheel being on the rest makes it conveniently located, along with the other controls, for the operator. The main points of design which enable the boring bar to be controlled by hand, are as follows:

The carriage is driven by a nut on the feed screw, the nut being supported in a bearing in which it can revolve. At one end of the nut is a worm gear meshing with a worm, the latter being turned one way or the other at will by the operator manipulating the handwheel. He can thus nullify the movement of the feed screw, reduce the movement imparted by the screw or make the carriage move faster. Left alone, the nut and carriage move at the uniform speed imparted by the feed screw.

Another feature of the carriage is the manner in which its tendency to tilt upward in front from the pressure of the boring bar is overcome. Ordinary procedure would be to gib the base of the carriage under the ways, in which case the strain would be on the bolts holding the gibs to the carriage castin·· avoid this, the carriage is cast with a hook-like bearing surface on the under side of the ways, and the gibs proper are placed on the top of the ways with suitable screws for adjustment. At the rear end of the carriage, gibs are used in the customary manner.

Shelburne, N.S.—The schooner, "Jean MacKay" was successfully launched last week. She is owned by Patten and Forsey, Newfoundland. Rigging is proceeding.



SHELL TURNING LATHE

The Courage of the Rail Splitter Needed Now

Canada's Industrial Future Now in the Melting Pot—A Better Labor Market Than Before the War Industries Came—What the Manufacturers Expect of the Government in Way of Co-operation

THE coming of peace was not a surprise to Canadian manufacturers. They had known for a long time that it was on the way. They had figured out in a good many cases what they would do when the glorious day of peace did arrive. But its coming has caused a little jerk just the same.

Right now is the time for the Canadian manufacturer to show his common sense. If he has been in war work he has been able to run his plant on munitions contracts while others went to the front and took their lives in their hands.

His business has not been confiscated. His home has not been invaded nor have the members of his family been maltreated by invaders. He has not gone hungry, nor has he stood day after day in the stench and stink of a trench. The chances are that his plant is in better condition than it was before the war contracts came. The making of shells was simply a temporary piece of business, and he knew it before he ever went into it.

Apart from all that, there is the fact that the future must be faced right away, and it must be faced fearlessly and cheerfully. The present is no time for blue-ruin blatherskites to be turned loose in the land. It is above all else a time for quiet and serious consideration, for real assistance on the part of the government, and for courage and confidence on the part of the manufacturers themselves.

Has Opened Canada's Eyes

Canada has had a good chance to get her eyes open during the period of munitions making. This country has found out that it can compete with the world. It has made shells and fuses, its mechanics have worked to finer dimensions than they ever thought possible, and unskilled men are able to value the thousandth part of an inch.

Canada has developed her industrial nerve to a greater extent than ever before. There is no reason why, having learned quickly the making of shells and their parts, she cannot turn to lines that were never known to mechanics here, and which, in years gone by, we have simply passed along to other countries because we have taken it for granted that their enormous equipment and their outstanding industrial prestige have entitled them to the trade without a struggle on our part.

The Spirit of Lincoln

Right now we need the spirit of Lincoln when it came to dealing with the steel monitor.

Early in the war of the secession, Ericsson, a Swede in New York, invented a monitor and needed a government appropriation to build it. G. B. Fox, Assistant Secretary of the Navy, said the heavy armor would sink such vessels. "But," answered President Lincoln, "is not that a sum in arithmetic? On our Western rivers we figure just how many tons will sink a flat-boat. Can't your clerks do the same for an armored vessel?"

But that was too absurd. Why was it necessary when all rule-of-thumb experience was against such an idea—for there are rule-of-thumb scientists as well as business men?

Congress passed a special appropriation for the purpose, but the naval board, consisting of a commodore and an admiral, condemned the monitor. Ericsson went to Washington and argued the question in the President's presence with this board of naval officers. Again the board ruled adversely. Lincoln overruled the board and told Ericsson to go ahead. The result was the "Monitor," and the subsequent triumph over the "Merrimac." The principle of the armored vessel was practically established. That was an instance in which the common sense of the rail-splitter, with the memory of his work on a Western river, overruled the rule-of-thumb "experts," who obeyed only the law of precedent, but had neither common sense nor open-mindedness towards innovation, as a part of their science. Lincoln's common sense could see no essential difference between the boats on the sea and the boats on the river.

Canada needs to develop a splendid disregard for the shiver that says, "Can't do it." It can be done. It doesn't make any difference whether it's been made here before or not. Neither shells nor fuses were made here before, and the operations on each are of very close dimensions. Canadian manufacturers doubted their own ability and the ability of their mechanics to make shells and fuses. Canadian manufacturers and Canadian mechanics have demonstrated beyond a doubt that they can make shells and fuses.

What Manufacturers Want

A deputation of Canadian manufacturers went to Ottawa recently and submitted the following outline on "reconstruction":

"The most pressing problem at the close of the war will be to find employment for all available labor.

"The manufacturing industry will be more seriously affected than any other, and it is certain that unless the government takes immediate steps to assist the manufacturers to increase the demands for their products they cannot cope with the situation.

"Therefore, we would ask the government to seriously consider the following suggestions:—

"1. That the plan for building up an export trade to be submitted to the Reconstruction and Development Committee of the Cabinet by the export committee of the C.M.A. be adopted.

"2. That a commission be appointed to take a survey of imports with a view to ascertaining what part of such imports could be made to better advantage in Canada.

"3. The government publicity department should be instructed to start immediately a nation-wide campaign to educate the people on the importance of buying Canadian products, and we respectfully suggest that the policy herein advocated be adopted by the government as a fixed and permanent practice for the conduct of government departments.

"4. That the Dominion Government, the Provincial Governments and municipalities be prepared to start immediately after the close of the war, all necessary construction work.

"5. That immediate steps be taken to ascertain what use can be made, after the war, of plants employed during the war for the production of munitions and war supplies.

"6. That it would be in the national interests if, as far as practicable, our soldiers were returned to the provinces from which they came and that in determining the order in which soldiers will be returned the military authorities be requested to govern themselves in conformity with information to be periodically supplied them by the government employment bureaus as is hereinafter described.

"7. That government employment bureaus be started immediately and that one of the principal duties to be assigned them be that of surveying the labor market with a view to furnishing the military authorities with monthly reports showing both by location and occupations the number of men for whom immediate employment can be found.

"8. That a practical land settlement plan be worked out at once and in connection with same the publicity department should start a campaign to educate our soldiers in the advantages of farming.

"An interesting series of booklets should be supplied to our soldiers while they are still at war particularly designed to show that community farm life can be made not only profitable but socially attractive in the older as well as in the new provinces.

"9. The publicity department of the government should start at once an 'optimism after the war' campaign, and in this they should ask the press of the country to co-operate.

"The country is drifting into a pessimistic frame of mind as regards 'after the war' conditions; this might easily bring about far-reaching depression unless it is quickly checked.

"10. When the time comes for demobilization the Militia Department and the government employment bureaus should co-operate in order that the lapse of time between discharge and employment be as short as possible. Congenial work is not only an antidote for discontent but it will be a pleasant relief for the soldiers after the ordeals of war.

"11. Having regard to the important part which research must necessarily play in Canada's industrial reconstruction the appropriation for that purpose should be increased to not less than one million dollars annually, and that the administration should be entrusted to a board of business men.

"12. That the government in shaping its policy with regard to the problems of standardization and the cost of living should follow the practice that has grown up at Washington of calling the manufacturers and the representatives of their employees into consultation; that price arrangements rather than governmental fixed prices be made the governing principle so long as such agreements can be arrived at that will accord with the government's own sense of what is right and fair.

"13. The Dominion Government should contribute to the Provincial Governments for the development of vocational training.

"14. The Dominion Government should take some action towards developing water powers now going to waste.

"The government may rely upon the manufacturers collectively and individually to do their utmost to provide employment and to show proper consideration for all those who may be handicapped by participation in the war, but if the government will co-operate along the lines suggested above the manufacturers will be in a position to render much greater service than would be possible under ordinary conditions."

Expect Trade To Develop

The agricultural implement trade should be in for a period of expansion and development. That seems to be the consensus of men close to the trade with whom CANADIAN MACHINERY has discussed the matter. But they also point out that much depends on the encouragement and assistance they receive from the government. The government can play the game of business or it can play the game of politics. The breach between Western Canada's agriculturists and the manufacturing interests of the Dominion has not been bridged, and it is just possible that, unless wise counsels prevail, scheming politicians may see the advantage to further selfish political interests by driving this wedge deeper and pitting the Westerner against the manufacturer.

There should be a better labor market than ever. Mechanics will not agree that experience on a one-operation machine makes a mechanic out of a laborer. It's not worth while to argue the point, because the mechanic's contention is right. At the same time there are thousands of men, and women too, who have had several years' hard experience at doing things exactly right in the production of shells. This experience will be of unusual help when they come to work at peacetime lines.

Canada's position is strong. She has a host of people holding her bonds. Interest charges, large though they may be, will be paid largely in such a way that the money will remain in the country. She has resources capable of enormous development, and she has a place in the eyes and heart of the world that will stand behind every move she may make in industrial development.

For the present the big task is to be brave, hopeful, and big enough to meet the new situations that will arise in the very near future. These problems can be turned into stepping-stones to bigger and greater things, or they can turn themselves, through pessimism and indifference, into millstones that will put industrial Canada in a position of near bankruptcy and misery.

It's up to you. See to it, no matter what your calling or capacity may be, that you meet every situation with a firm resolve to conquer it, and that you regard every occasion as a great opportunity. Do this and the future has a wonderful development in store for us.

THE VISION OF AN OLD HAT

(Copy from New York Times)

Ninety-seven million rosy and comfortable people in this country pick out three million men and say to the three million men they have picked out: "You go into the jaws of death for us!"

Then what do the ninety-seven millions do?

God help us if there is a man or woman left before this week is over who is not acting or trying to act as if he or she were the whole ninety-seven million!

When a man cries out to me three thousand miles away: "Oh brother, won't you lend me fifty dollars to die for you with! "What can I do?"

I know one thing.

I am not going to be caught by my God higgling on the edge of his grave with him—with the man who is dying for me—as to whether I will have to run a little risk or not, or go without a servant or not, or wear my old hat!

What has risk to do with it?

The more risk goes with a bond the more decent a bond feels! My brother says to me: "I give my life for you!" I say to him: "Here is another inch I smoke on my cigars for you!"

Every man speaks for himself, but as for me—when I think of him—of the man who, without knowing it's a cross, has died for me—when I think of Him I wear my old hat through crowds while the tears roll down my cheeks.

How strangely the world is lighted up as I see the soldiers troop down the streets.

I think of nine hundred thousand dead English boys.

I think as our boys' faces pass of the nine hundred thousand dead English boys.

How the nine hundred thousand dead English boys light our boys' faces up!

I stand on the curbstone and watch our boys.

Down the street their faces go, and out to sea, silent, unmentioned, unknown, while the bands play —each with his shadowy cross on his shoulder!

Hundreds of thousands. Then more hundreds of thousands!

Hundreds of thousands of soldier boys bring back to me my God!

The Cross is no longer crowded off on to a lonely hill in Galilee two thousand years away.

I walk as in a dream past hundreds of thousands of crosses down the street!

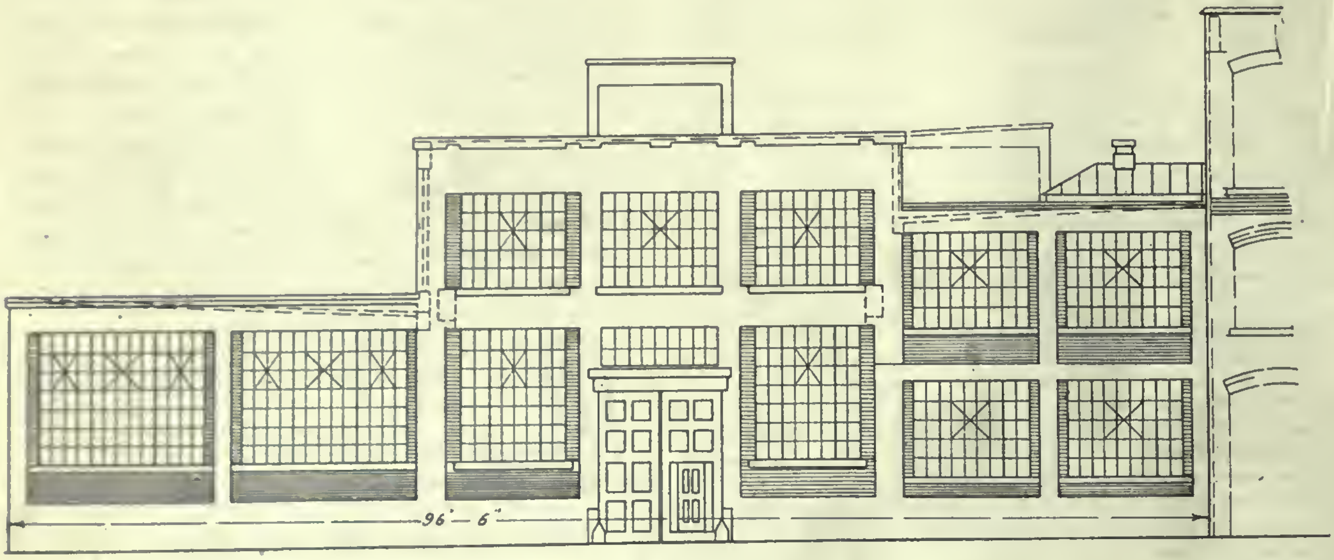
I have seen two thousand boys with crosses follow Christ up Calvary

That we may have a world children can say their prayers in!

AN OLD HAT SEEMS LITTLE ENOUGH

"GO! GO! NO LEFT TURNING"

New Grey Iron Foundry of Darling Bros.



THE steady increase in the business of Darling Bros., of Montreal, has required considerably more factory space during the past few years. While much of this has been the result of munition work the greater portion of the increased activity has resulted from the enlarged volume of orders for general contract work. The most recent expansion is in the foundry business, this development being virtually forced upon them by the existing situation created by the contingent difficulties in obtaining the necessary castings for the manufacture of their product. The inability of many foundries throughout the country to secure sufficient raw materials for their usual operations, created a situation where many essential industries—dependent upon outside sources for fundamental material—were brought to the point of establishing for themselves a source of supply upon which they could rely.

The new foundry of Darling Bros. had been under consideration for some time but was necessarily hastened by abnormal conditions arising out of the war. To meet the pressing demands for greater output the decision to construct the foundry was shortly followed by active operations, and work on the foundations was started early in the spring, and early in October the first cast was successfully made. The foundry building, which consists of the new addition and a small portion of the old structure which houses some of the auxiliary equipment, covers an approximate area of 18,000 square feet. The main portion is of the lantern type which provides abundant lighting to all sections of the floor and gallery, where the charging floor is located. The cupola now installed is of the 10-ton continuous type, and provision has been made for an additional unit of similar capacity. The blast for the cupola is supplied by a No. 4 Roots blower, with a capacity of 4,000 cubic feet of air per minute; this unit is operated from the line shaft.

Two ladles, one of 2 ton and one of 1 ton capacity, made by the Whiting Equipment Co. are provided, each of these being fitted with improved pin spur gear opening arrangement. The core ovens are built of brick and are equipped with the necessary shelves in addition to the portable car. Balanced lifting doors are also provided. The smaller oven was installed by C. J. Woodison Co. of Detroit, and is of the stationary type, set in brick. The cores are placed on swinging shelves, which operate independently of each other, allowing of the removal of the cores without hindering the baking process of the other shelves.

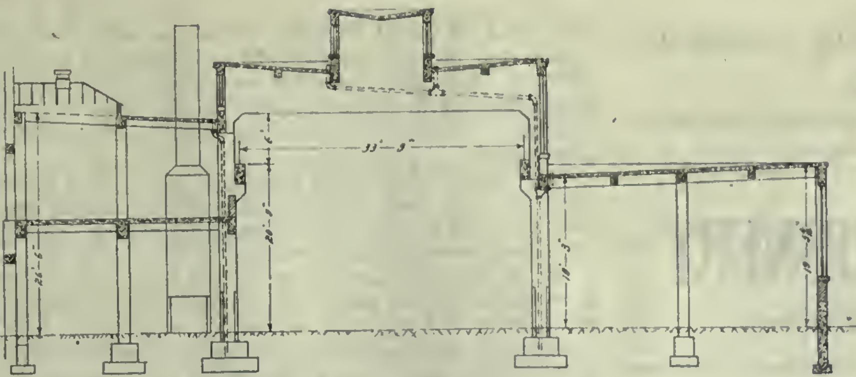
The central portion of the floor, where the heavy work will be done, is provided with a 4-ton electric traveling crane, operated and controlled from the floor level.

The fettling shop is amply provided for the cleaning and dressing of the castings before the same are transferred to the machine shop. The large Whiting tumbler is of the steel plate barrel variety driven off the line shaft. Emery wheel and air hammers are also provided. A power-driven elevator with a platform 5 ft. 6 in. by 8 ft., and with a capacity of 3,000 pounds, has been installed for supplying the charging floor.

The building is heated by the Webster vacuum system of steam heating, steam being delivered through a reducing valve from a 40 horse power return tubular boiler. The condensation is returned by means of a 5 x 6 x 10 vacuum pump, discharging to a receiver, from when it is returned to the boiler by a 5 x 3 x 6 boiler feed pump in the usual way. There is installed 2,000 square feet of direct radiation divided into 14 units capable of maintaining a temperature of 60° during the most severe weather.

Adjoining the foundry and in a section of the old structure is the pattern making department. This space has been enlarged and equipped with the latest type of modern wood-working machinery. This department which was formerly located in the main building across the street, is in charge of a competent super-

POURING: DARLING BROS.' FOUNDRY



CROSS SECTION THROUGH FOUNDRY

visor of long experience and a staff of efficient pattern makers.

The primary object of the recent development was for the purpose of supplying the need of their own business, but it is expected that general contract work will also be a feature of this new activity.

T. Pringle and Son, architects and engineers, were the designers and erectors of the building and the finished structure exemplifies the latest and most efficient practice in foundry installation and operation.

It is stated that during a recent French offensive the consumption of petrol for the army and air service was at the rate of 1,800 tons per day, which represents a daily consumption of approximately 500,000 gallons of petrol.

SUCCESSFUL WITH A "VOLUNTEER PLAN" AT THE BOWSER TANK AND PUMP WORKS FORT WAYNE, INDIANA

THE Fourth Liberty Loan Campaign at the Bowser plant was conducted strictly according to a "Volunteer Plan." The Allen County, Indiana, organization put on a "voluntary campaign" and the factories were asked to join in the spirit of the undertaking.

In previous campaigns a soliciting squad was organized which enlisted the services of practically 175 workers. The head of each department was designated as captain, and he would appoint as many lieutenants as necessary to get the subscriptions in his department.

This "Volunteer" campaign made it unnecessary for all of these workers to solicit the subscriptions. Everyone was urged to buy as many bonds as they could possibly afford, without being personally called upon to do so.

In consequence of the request, the old Bowser team organization which have operated in the past were not in existence. Three booths were set up in the plant where subscriptions were received. There was no soliciting—there was no urging—but every man and woman was permitted to work out the problem with his or her own conscience, and be the sole judge.

When the voluntary campaign closed Tuesday night, October first, the results were counted up and it was found that the conscience of the Bowser employees had been seriously at work without a single prompting from the old-time team organization. The employees had subscribed of their own free-will a larger amount, number of people considered, than was subscribed in the Third Liberty Loan campaign. The fact attests to the soundness of the voluntary subscription plan of a conscience campaign and at the same time speaks well for the state of health of the Bowser Conscience.

Fourteen hundred and ninety-five subscriptions were contributed to the Fourth Liberty Loan. No branch office nor salesmen's subscriptions were included in this. The firm deemed it advisable for branch office employees and salesmen to subscribe locally. The contributions were therefore solely from the home office and factory forces.

After War Orders—What?

A PERUSAL of the armistice terms imposed on Germany make it quite certain that the German war machine has been smashed and crushed for keeps. The Allied nations, having been driven to war, resolved that they would make an end to it, and they have.

It almost looks like taking away a man's clothes and not extending the courtesy of a barrel in which to sneak home.

As a matter of fact, the German emperor doesn't appear to have a back alley left open to him.

Canada faces a new world. For all purposes, consider war contracts as finished.

Get the words of Prime Minister Hughes of Australia, who said:—

> "The war has destroyed all the landmarks of the world in which we used to live. Every day we confront a situation without precedent, and ancient traditions are buried beneath the burning lava of war. Nothing matters but that we should learn by experience to no longer waste our time in profitless doctrinaire discussions or drift with the backwaters of inaction."

That practically amounts to the statement that out of the cauldron of war has come a time for the Canadian people to develop to the full the initiative with which they are endowed; to forget past precedents that have held them in check, and to press on until they occupy the place in the world for which they have been so wondrously endowed by raw materials, boundless resources and a race of splendid men.

A Celebration With No Booze

A NUMBER of cities in the Dominion had a scare celebration on Thursday on the strength of the report that an armistice had been signed and fighting had ceased. In Toronto, during the affair, the suggestion was made in several sources that the ban on liquor should be lifted for 24 hours, in order that the celebration should be a mad one and a merry one.

Fortunately the suggestion never got to the stage where it had a good chance to sprout.

There is a feeling that liquor should have been freely spilled during the influenza epidemic. Booze has a string of victims to its credit that would make the death list from influenza look simply like an index to the chapters that follow.

A man who cannot celebrate the coming of peace and remain in his sober mind and in possession of all his senses had better not celebrate at all. It must be remembered that booze was shut out of this country in order that we might be more efficient to wage war. This young land gave a practical demonstration of her moral strength that England could not give. The Old Land was weakened by booze, and yet in the face of national disaster it could not rise in its might and strangle the slimy thing.

The industrial world in Canada is better by a thousand per cent. with John Barleycorn dead and buried than it ever was with him trotting around and making damn fools out of otherwise sensible men.

Be mighty careful when you take a hand in the business of rolling away the stone that is holding his carcass under the ground for the time being.

Booze is not dead yet, but the people who were soused in it before have had a chance to pull themselves together and appreciate the sensation of being sober and decent and 100 per cent. efficient.

Canada's a Great Place

CERTAIN factions of the Canadian press are given at times to discussing the degree of imperialism to which they are addicted. Apparently there are lukewarm imperialists to whom Canada is, and always will be, a colony and nothing else.

With all due regard to the policy of some of these papers, there is a great big work that remains for the Canadian papers to do, and that is to speak and think in terms Canadian.

This country is a great proposition. There is none better. The children in the schools should be taught that it is the greatest place under the sun. They should be etrly given the idea that Canada is a nation, not an offshoot.

Canada has been giving a demonstration in the last few years that should serve to let a little daylight into the skulls of some of the colonial-saturated folk.

This country has made a record on the field of battle that has not been surpassed by all the military traditions in the world. The Dominion has shown that the mechanics of this country are capable of making the Canadian shell shops the finest in the world, and shell and fuse making were new things to the Dominion. The very fact that the Dominion was able to maintain her leadership in this business shows that, with equal opportunity she could do the same in any other line that her pepople had the opportunity of tackling. Canada has developed her industrial nerve to quite a degree, and she is not minded to let it grow weak after the making of shells has ceased.

All this is well, but there are happenings at Ottawa that the Canadian press would do well to watch and watch carefully. This country is being too much governed by orders-in-council and the rule of censorship. The censorship of the Canadian press was never justified, and the serious-minded people resent it. It was a slam at the whole decent press because certain authorities had not the courage to handle a few renegade papers that council is dangerous; it is not a good thing for the government itself that has to abide by the decisions of the few of its members who put these things across; it is not good for the people of the country at learge who have to live under the half-baked legislation that is galloped through. The press of the Dominion can right now perform a real service by calling, irrespective of politics, for a cessation of the ruling of Canada by orders-in-council.

THERE'S three things you can't beat, the race horses, the stock market and the booze.

* * *

DON'T imagine you're a great patriot because you buy a war bond. It's a gilt edge security, and non-taxable. In fact it's the best investment in sight, and buying them isn't nearly so risky as fighting at $1.10 per day.

HAD TO START ALL OVER—BUT HE DID IT

Frank W. Barron Recollects His Apprenticeship at Time the Roller Boat Was Being Built

THE temperance wave swept many hotelmen off their feet. One of them was Frank W. Barron—for three years proprietor of the Oshawa Hotel at Oshawa, Ontario, and now, little more than two years later, mechanical superintendent of British Acetones, Toronto, Limited. This is the story of how he came back.

"Remember the Knapp roller boat?" he asked. "About the time I finished my apprenticeship with the Polson Iron Works she was ready to ride the Bay. I had helped to build her.

"Knapp was a clever fellow and he had several intelligent and moneyed backers. But a number of the workers had misgivings. One of them swore she would fail. To him—a little Irish sailor from the Upper Lakes—she was a monstrosity, a fool thing designed to outlaw the sanctity of water."

Five years in the Polson Works was time well spent to Frank Barron, ambitious to become a mechanical engineer. Not more than eleven or twelve years old when he started at Polson's, he was still a lad when he left to work in Eaton's power plant under E. J. Phillip, who is now with the Belleville Locomotive Works.

It was while with Phillip that young Barron formed the study habit. In fact, he was probably one of the first Canadians to mix advanced theory with practice by enrolling for a correspondence course in mechanical engineering. But toward the end of five years, hard study on the top of hard work—and it was work underground in the Eaton plant—started inroads on his health.

He left Eaton's and went as erecting engineer with the Wrought Iron Range Company, of St. Louis. And with the change his health improved — likewise his finances.

But when all's said, there's always room for another snug nest among Canada's maples, and Frank Barron, acutely aware of this after five years away, demonstrated that no inducement in even "show me" Missouri could hold a homing bird.

The Copland Brewing Company started him as chief engineer; promoted him to plant superintendent; later to superintendent of construction. And when he signified a desire to go into the hotel business, it was this company's capital plus his own considerable savings that gave him proprietorship of the Oshawa Hotel.

"Out of the wreck," he said, speaking of the prohibition enactment, "I saved nothing but the farm that had provisioned the hotel table. I'd have gone on it at once had I known farming, for there were my wife and three boys to provide for.

"One day I heard that the Whitby Asylum needed a night engineer. I applied for the job and got it. And I managed all right, for I had plenty of time to think before I had to act. But had I first of all attempted the job I've here, or one like it, I'd have surely failed.

"As it was, my first few weeks in this plant were nearly too much for me," Barron said seriously. "I sat up all night studying my plant problems more times than I'd care to tell you.

"Two and one-quarter tons of coal consumed to every one ton of corn distilled in making acetone—that was the situation when I came here. But since then, by utilizing exhaust steam until by making other plant changes, the management has dropped the consumption of coal to seven-eighths of a ton to one of corn.

"Other problems were quite as difficult. The men had to be patiently trained. What that meant you'll understand when I say that we have miles of steam pipes and that the best steam fitter might easily make serious mistakes and never depart one iota from standard practice.

"For the making of acetones and the by-product butyl is purely a germ proposition. It calls for a delicate distillation process, for pipes that are steam tight, for frequent flushing, thorough sterilizing, for care surpassing that of an expert dairyman handling sweet milk."

"And just what is acetone?" Barron was asked.

"It is a cordite solvent—a munition of war."

If ever on Trinity Street you might find it worth while to step into Barron's office. On the wall above a subordinate's desk and in full view of his, you would notice a score of simple clips holding work—orders for as many departments. He can tell at a glance whether work for any one or for all departments is at high ebb or low.

On the wall opposite his own desk are two or three large white-prints captioned "Late and Absent." No need to waste words on a delinquent; just show him his record.

But supposing you don't carry away an adaptable idea, you'll have met Frank W. Barron—a young man who has mastered the theory and practice of mechanical engineering, mastered both so well that he came back and made good.

Hanging to a Poor Old System

THERE is still a tendency to adhere to certain regulations regarding civic business that serve no other purpose than to be a nuisance. There was a case in point in an investigation that was being carried on in Toronto a few days ago. Here is the way in which it was reported:

> "Did you know that Miles Vokes' sons were selling to the board?"
>
> "I knew the British-American Hardware Company were selling. I spoke to Mr. Vokes about it, and he said, 'Hodgson, my position is clear. I have had legal advice, and am told that a joint stock company is quite legal.'"
>
> "You knew that Mr. Vokes' sons were the British-American Hardware Company?"
>
> "I knew nothing direct. It was only what I was told."
>
> "Don't you think it was a vicious principle?"
>
> "Not if they were the lowest tenderers."

Now, just where the vicious part of the system comes in, it is hard to understand as long as the whole work is let by tender, and the tenders are handled honestly and in public.

Civic regulations provide that men who sit on councils or commissions shall not sell to that body. What is the result? A capable man, one who might make a splendid public servant, keeps out of public life because he does not feel in a position to sacrifice his business.

There are instances all over the country where this same thing is working to very grave disadvantage. It is easy to imagine a case where there would be plenty of grafting were it possible to do the purchasing otherwise than by tender. But the public can be protected and well protected if the public tender system is used, and if these tenders are opened at a certain time in public. Publicity is in this case the safeguard, and it will also allow a man to serve his community without having to hang up a shingle saying, "I'm under suspicion because I am a member of the council."

CANADIAN MACHINERY learned that British Acetones, Toronto, Limited, manufacture seventy-five per cent. of all acetones made in Canada, and that a good deal of this remarkable success is owing to Colonel Gooderham's executive ability and long experience in the distillery business. For over two years he has given his plant and his personal services gratis to the British government.

MARKET DEVELOPMENTS

U.S. Government Stops Chance of Any Panic

War Contractors to be Treated Very Liberally and Given Every Opportunity to Get Back on Peace Lines Again—Should Be a Better Labor Market in Canada Now Than Before the War

EVERY precaution has been taken in United States against allowing the bottom to fall out of business by reason of the cancellation of contracts. It is only following the logical course of events that these should go by the boards in a short time following the cessation of hostilities, but it is of the utmost importance that the operation should be completed with the least possible derangement of the industrial fabric of the nation. Any movement that is taken in United States in this direction will certainly have a reflex influence on this country. The government will accept and pay for all materials finished at the time of cancellation, and will also buy all material in process at prices including a pro rata of profit. The term "material in process" will be interpreted liberally to include material secured for the purpose of filling the contract, even though no actual work has been done on it. This plan has been submitted to the leading holders of U.S. war contracts and they approve of it. It seems only reasonable that the same arrangement will be made with Canadian contractors who have unfinished contracts for the U.S. government.

The signing of the armistice has been the signal for a lot of neglected business to come prominently to the front. Railroad shops orders for machine tools are reported in generous quantities at U.S. points. This class of business has largely been denied access to the markets for some time past, and now that the war pressure is removed, there is likely to be considerable activity and renewed buying.

Industrial Canada faces its period of reconstruction right now. It has been anticipated in many cases, and firms have ambitious programs that should work out to good advantage if the proper support is forthcoming. Other firms were war favorites and nothing else, and they will simply drop out. Although there may have been little in the mechanical training a person received in a shell shop that would fit that person for machine work after, there is another side to the matter. Those who have worked for some years in shell shops have become accustomed to working to very fine dimensions. They have learned to do things within a ten thousandth of an inch of being absolutely correct, and this training is not going to be lost. The shell shop workers will carry a lot of it into other lines, and in that will come the benefit of providing Canada with a better labor market than she ever had before.

SUPPLIES WILL HANG OUT LONGEST

Will be Sold to War Trade as Long as There is a Shell to Be Turned

TORONTO.—Munition shops in Toronto started work on Tuesday morning as though there had been no cessation of war. Of course the management and those in the works know very well that it will be only a short time until these operations shall have ceased. There does not seem to be any tendency to adopt the guillotine method in cancelling these contracts, rather does it seem likely that they will be dropped as easily as possible, with a view to avoiding anything approaching a panicky feeling in the industrial or labor world. It is intimated that the policy of United States authorities will be to pay for all material in the process of manufacture, and to make readjustment on the basis of labor costs on material that is not needed. It is likely that the same treatment will be extended to shops in Canada handling American orders. It may be that before this reaches the readers a statement may have been sent out from Ottawa covering the case in full.

Dealers in Canada are not quite clear yet on some of the rulings that have been made at Washington regarding the placing of stock orders with firms on the other side of the line. The interpretation of the order made at Ottawa does not coincide with that at Washington in detail. In fact in a good many cases there has been quite a bit of confusion regarding priorities and licenses. Some of the larger dealers have found it necessary to institute and maintain a separate department to deal with these matters.

One of the dealers here expressed the view this morning that the day of the single-purpose machine had not passed with the end of the war contracts. "I believe that production machines in specialty work will be more than ever used in this country, and that to that extent they will replace the general purpose machine. The best results have been obtained where each operation in the shop is specialized."

This same dealer refused absolutely to believe any blue-ruin talk. On his desk were letters from four firms that had not in four years purchased a dollar's worth of equipment outside of war work machinery. They stated that they were desirous of information regarding certain lines of machinery that the dealer had practically gone out of for the period of the war.

The Supply Departments

Supplies for war shops will be the last to receive notice to quit. As long as there is a shell made it will be necessary to have supplies for the work. Some of the dealers here are fairly well stocked with this material. They are getting rid of it in fair style, however, and by the time the munition contracts are done for they will be pretty well squared away on the material that they had to purchase at war prices. War shops have been buying their supplies rather close for some weeks past so that there will not be any particular jar in this direction.

The Steel Stock

Most of the houses doing a warehouse business in steel are in good shape. That is they are fairly well cleaned out of material that has had a period of very high and inflated value during the period of war buying. In some cases, however, there are stocks held that will not be readily disposed of at prices that will clear the dealers. For instance, some places have a fairly large amount of nickel steel on hand. When munitions contracts and airplane building fall off the big demand for this in war work will be done for. It is used for automobile axles, but builders of cars are not likely to pay war prices for anything that will be sold in the after-war market. This opinion is simply based on presumption.

Dealers do not look for a slump in the price of the basic article, steel. They anticipate a higher level than is paid at U. S. points of production now.

There seemed to be a tendency all through the market to look for good business ahead. The trade is willing to admit that there may be a period of quiet trade, but the fact that the war is over and the Allies are more than conquerors is enough to counterbalance this many times over.

EVERY SAFEGUARD PLACED AROUND CANCELLATION OF THE WAR CONTRACTS

Special to CANADIAN MACHINERY

PITTSBURGH, Pa., Nov. 14.—Pig iron production in October fell off about 1.3 per cent. from the September rate and steel ingot production about 3.2 per cent. This is contrary to precedent, as October, with its favorable weather conditions, usually shows exceptionally heavy production rate. This year there were two special factors. In the first place September production was very heavy, showing a sharp gain over the August rate, while in the second place the influenza epidemic very considerably reduced working forces at blast furnaces and steel mills. The production of coke was materially reduced, but it appears that the blast furnaces suffered from depletion of working forces more than from shortage of coke.

The production of steel ingots in October was at the rate of about 45,250,000 gross tons a year, and that is in itself a favorable showing, comparing with actual outputs of about 43,700,000 tons in 1917 and 41,400,000 tons in 1916. Productive capacity, with all conditions favorable, is fully 47,000,000 tons a year, perhaps more, but in these war times conditions have not all been favorable. There has been some shortage of labor, and in a few cases inefficiency of labor, while there has been a shortage of good grades of scrap. The total tonnage of scrap has been fairly large, but it has run to the lighter grades, really standard heavy melting steel being in poor supply.

Cancellations of War Contracts

It goes without saying that the cessation of hostilities means a great decrease in the total amount of steel required for war and near-war purposes, and many contracts have to be canceled. Already there has been worked out a definite plan for such cancellations as may be necessary, to cover the case of contracts that do not carry their own cancellation terms, and the majority of contracts do not. The government will accept and pay for all material finished at the time of the cancellation, and will also buy all material in process, at prices including a pro rata of profit. The term material in process will be interpreted liberally, to include material secured for the purpose of filling the contract, even though no actual work has been done on it. This plan has been submitted to leading holders of contracts and meets their approval. The Government having purchased material of various sorts will be in position to sell it at the best price obtainable, as values will run under the new conditions, and in most cases the material will no doubt be sold back to the contractor. The government has established a board of military men to hear and adjust complaints under these contract cancellations, so as to avoid what would otherwise be tedious delays in adjustment.

The first cancellations will doubtless be of contracts for shell steel for the Allies, the next of contracts for shell steel for the government. At all times there is a large quantity of shell steel in transit and in process of manufacture, and even the instant cessation of all rolling of shell steel would allow for a large supply of shells for emergencies during the period between the cessation of hostilities and the final assurance of absolute peace.

Ship Steel

The Shipping Board continues working out its policy of retrenchment, but this is retrenchment in expenditures, the introduction of economies, rather than any material reduction in the quantity of ships to be built. Relations with inefficient yards will be discontinued, and various contemplated shipyard extensions have been abandoned. The program to build 15,000,000 tons deadweight of vessels, of which about 2,500,000 tons has been completed, is left intact.

To the steel trade, especially as regards conditions during the next few months, the important item is a decision not yet officially announced, but quite well known in the steel circles immediately involved. That is, to reduce the weekly quota of ship plates called for to been held to a schedule of 50,000 net an amount not exceeding the quantity of plates that is at the same time actually passing into vessel hulls. This will effect a reduction in weekly deliveries of plates of from 30 to 50 per cent. For several months past the plate mills have tons weekly of plates for account of the Fleet Corporation. This would cover approximately 700,000 tons deadweight of steel shipbuilding per month. The actual average of steel hull launchings in the past few months has only been between 300,000 and 400,000 tons. As a consequence, plates have accumulated. There must be a large tonnage in transit and in course of fabrication, but the accumulation apart from that is now understood to be about a million tons. When it was important, regardless of expense, to complete every vessel possible, it was right to have a surplus at every point along the line, even though shortage in some particular retarded the use of the material or facilities. Thus the "bottle neck" for months past has been the supply of engines, boilers and other appurtenances. Now, when money must not be spent so lavishly, these extreme factors of safety are not desirable. Hence plate deliveries are shortly to be curtailed, so that there will be no further accumulation, and the present accumulation may even be reduced. The reduction, however, will only be temporary, as Director General of Shipbuilding Schwab has just stated that the present objective is 700,000 tons deadweight of vessels per month, and this rate is expected to be reached next Spring. That rate, or even a greater rate, will be continued for a long time when once it is attained. The rate would require about 50,000 net tons of plates a week, the quota recently in force, so that the former rate of deliveries is eventually to be restored. Meanwhile, there will be more plates for other purposes. Foreign buyers are keen to secure plates and there are indications that they are ready to pay very high prices, above the present Government limits. It appears even that some such purchases have been made. Plates in the domestic market, on the other hand, are expected to rule at less than the present level.

Price Control

The War Industries Board is making progress in its plans for continuing control of industry after the war. Its life is assured to the President's proclamation of peace, which will necessarily be months hence, but legislation is to be sought covering a further period of six months. This plan meets with general approval among iron and steel manufacturers, who expect that without such control there would be a period of light demand, while the market finds itself for extended period of prosperity that nearly all expect to follow the war. In that period the market would presumably slump to a level far below that subsequently to be established, and this would cause disorganization.

There are some iron and steel manufacturers, however, who apparently would prefer the slump. Doubtless their idea is that there is so much to be done by way of reducing costs that a period of slackness would be useful in helping this cost readjustment. They are thinking of wage rates among other items, but it is really doubtful whether wages can be reduced much, if at all. A couple of years or so ago the trade was almost a unit in expecting, and desiring, a general "shake-out" after the war, to get costs down, believing this to be imperatively necessary, but a great many have changed their minds meanwhile, and expect wages, commodity prices and practically everything to continue on a much higher level after the war than obtained before, probably for years afterwards and perhaps for an indefinite time.

RAILWAY SHOPS COME IN THE MARKET

Will Do a Lot of Buying Now in Order to Catch Up With Repair Work

Special to CANADIAN MACHINERY

NEW YORK, November 13.—The topic of all-absorbing interest in the machinery industry to-day is the effect that the end of the war will have upon orders for machinery to be utilized in the manufacture of war munitions. In a general way the government is relied upon to prevent any hardship being visited upon either manufacturers or dealers in machinery. In the Eastern territory last week there was evidence of a conservative feeling and of the holding back of prospective orders for machine tools that were expected to be needed for the additional manufacture of guns, shells, small arms and other war munitions.

Thus far the most of the cancellation of orders for machine tools have come from shipbuilding concerns and most of these resulted from the abandonment of the Alameda ship plant by the Emergency Fleet Corp. Cancellation of machine tool orders have been guarded against by provisos in contracts placed during the last six months or a year, stipulating that one third or one-half of the order be paid for in cash upon acceptance of the contract and the balance of the purchase price be subject to sight draft against bill of lading. Such contracts were entered into, however, only with untried interests, this precaution not being considered necessary in dealings with regular customers with stable lines of manufacture. Not a few contracts were recently written with a non-cancellation clause. This form of contract has been quite generally adopted in the last month.

On the other hand a few large manufacturers of machinery have taken a stand against the non-cancellation clause, believing that as the government is practically the source of all work for which machinery has been purchased, that satisfactory arrangements will be made covering the period of reconstruction.

Upon the cancellation of contracts for troop ships, made by the Emergency Fleet Corporation with the Bethlehem Steel and the New York Shipbuilding Corporations, it was ordered that work on machinery for these government yards be suspended. This order, however, applied only to equipment upon which manufacture had not yet been commenced. It is now understood that the Fleet Corporation has called upon each machinery contractor to report the exact status of machinery orders at his plant.

It is understood that the twelve-inch howitzer plant planned for construction at Nicetown, Pa., by the Midvale Steel and Ordnance Co. will not be built. No action has been taken toward the purchase of tools for the manufacture of pistols under recent contracts, and no orders for machine tools have been placed for the additional machine shop at the Charlestown, Mass., Navy Yard, which, with equipment, was to cost $900,000. It is expected also that the $1,000,000 list of tools for the Osgood, Bradley Car Co., Worcester, Mass., will be withdrawn.

Railroads, however, have been buying machinery more actively in the last week and are expected to continue placing important orders for shop equipment. The Pennsylvania R. R. is buying tools for its locomotive repair shop now being built at Marietta, Pa. The New York Central is placing orders for cranes for its East Buffalo car shops. The Baltimore and Ohio has also bought tools; other railroads have put out inquiries for machinery, including forging machines, which will probably be purchased for 1919 delivery. The Pennsylvania R. R. will spend about $1,000,000 for building and equipping repair shops in South Philadelphia.

SERVICE FLAGS IN THE DUNDAS SHOPS

There was no great stimulus required in the plant of the Bertram Company in Dundas to put them over the top in the Victory Loan campaign. The payments on the last loan had just been completed on the company's extended payment plan, and the receipt of these documents just on the eve of the present loan had a very good effect in bringing home the real value of the proposition. The company used a large envelope, printed in red, to deliver the paid-up bonds, and also to solicit subscriptions to the new issue. The envelope stated, "This is YOUR Victory Bond, bought and paid for out of your weekly earnings. Perhaps the payments pinched you sometimes, but—would you have made this saving if you had not subscribed for this bond? You have shown yourself what you can do. You are again offered the same opportunity to save systematically."

The publicity was well attended to. T. Stevenson, from the Trades Council, Toronto, was secured to address the men, and he put the case in a very plain and pointed way and made a good impression. When a representative of CANADIAN MACHINERY was at the Bertram plant a few days ago there were service flags proudly displayed in a good many of the departments. The sum of $150,000 was the total subscription. The company needed 813 subscribers to get a service flag, and the total a few days ago was 940. In fact the Bertram plant is pretty close to 100 per cent. in the matter of the number subscribing.

In the Pratt & Whitney plant, which is just across the road from the Bertram plant, the same good success was met with in the search for purchasers of Victory bonds. There were several rather amusing events here. The company had eighty-two men on the roll, and there were eighty-four applications taken in. The explanation was given that two men had been taken on since the census was taken. There are also two boys in the office at this plant that have at an early age developed the financing instinct to quite a degree. These lads made the proposition that if their wages were increased they would gladly subscribe to the Victory Loan fund. Pratt & Whitney won their flag in short order.

HOW WELLAND WENT AFTER THE BIG LOAN

The following tables show the records made last week by Welland's industries. Up to noon last Saturday ten plants exceeded their quotas and work is still progressing in all the plants.

The following industries have exceeded their quota by the percentages shown: Volta Company, 145 per cent.; Electric Steel & Metals, 117 per cent.; Electro Metals, 95 per cent.; John Deere, 73 per cent.; Canadian Billings Spencer, 75 per cent.; Union Carbide, 69 per cent.; Plymouth Cordage, 58 per cent.; M. Beatty & Sons, 50 per cent.; Chipman Holton, 46 per cent.; Canadian Steel Foundries, 8 per cent.; Empire Cotton Mills, 5 per cent.

The following percentages show amount of quota raised by these plants: Page Hersey, 94 per cent.; Welland Machine & Foundries, 93 per cent.; Shipbuilding Company, 75 per cent., and Metals Chemicas, 70 per cent.

100 Per Cent. Industries

Every employee in the following plants have bought bonds: Canadian Forge, John Deere, Electric Steel & Metals, Empire Cotton Mills, Union Carbide, Volta Mfg. Company.

Up to Saturday noon the following amounts were raised in the factories named:

Electro Metals	$117,000
Canada Forge	105,000
Union Carbide	76,400
Canadian Steel Foundries	75,850
Empire Cotton Mills	57,000
Plymouth Cordage	47,500
Canadian Billings & Spencer	47,400
Page Hersey	41,650
Shipbuilding Company	38,000
Electric Steel & Metals	31.300
John Deere Mfg. Company	17,100
Beatty & Sons	15,600
Metals Chemicals	10.250
Volta Mfg. Company	8,800
Welland Machine	6.000
Knitting Company	3,700
	$698,550

Conciliation Will Do Much To Solve Problem

Imperial Munitions Board Let Some of the Contracts Run to Ease Labor Situation—Minister of Labor Sees No Cause to Anticipate Trouble in Handling the Situation

Special to CANADIAN MACHINERY

OTTAWA, November 19.—Ottawa's not the same old Ottawa that it used to be. There's too much business being carried on here to permit of the old political atmosphere thriving and having full fling. The ward heeler is not cutting much ice in the capital just now, although his day may come again. But the people who are here and who get the hearing are the men who are in touch with business, who have much to do with the employment of labor, who are planning how best to pilot their several concerns from the war-time trade to the basis of peace-time work. Of course it's all a little rough on the old-time politician, but it's a fact, and for the present chapter his likes or dislikes are not of very serious consequence.

As far as CANADIAN MACHINERY can find out, the matter of after-the-war trade has been put right in the centre of the ring. It has preference over everything. In fact its rating on the basis of priorities is A1. Men are discussing it. It's the talk at the Chateau, in the government offices, and in the inner chambers as well. So if talking and discussing are going to settle the after-war problems they will be polished and turned until they dazzle. As a matter of fact the great "What next" chapter is the centre of all interest. Anything else that gets a chance simply flies off on a tangent.

Stopping the Orders

CANADIAN MACHINERY learns that the extension of British orders after the cessation of war was largely out of consideration for the men employed in the works, and partly from a desire to avoid dumping thousands into the labor market at once. The Munitions Board do not want the shells. That is pretty generally understood. Some weeks ago—in fact at various times—they have drawn the attention of the government that the day was coming when they would not give out any more orders, and they have urged the government to look forward to that time, and guard against it. So it is that at the present time the Imperial Munitions Board is in the position of the purchaser buying clothes that he will not wear, or of the householder loading up his larder with food that he will not need. Poor business, you say? Yes, it is, and the chances are that the head of the Imperial Munitions Board would not be inclined to dispute the point. He knows a real business deal about as thoroughly as any man in Canada, and if the matter were looked at from that slant alone the contracts would probably have been cancelled the day the armistice was signed.

The Other Side

Several other ways were considered. It was suggested at one time that the munitions workers should be given a bonus of a couple of weeks' pay in lieu of any notice that their services were no longer required. There were objections to this plan as it was felt that there would be an inevitable glutting of certain labor markets, and it was decided to make every effort to avoid this, so the plan, which meets with the approval of Sir Joseph Flavelle, was brought out, of giving contracts until the 14th of December to run. That was coupled with instructions not to take any new material into the works after Friday night, the 15th. Those in the rough turning would thus be let out first, probably about ten per cent. of the force.

Not Likely to Continue

The suggestion has been made here that the Imperial Munitions Board should continue in office. They have a splendid organization that has produced results that the country hardly appreciates, and if it did understand their work better it might add to the size and insistence of the request that they continue in office. When questioned on this point Sir Joseph simply remarked that the work now before the Imperial Munitions Board was to liquidate as quickly as possible. "We were brought into existence to perform a stated work. That has been done, and as soon as possible we will cease to exist." That apparently is the feeling of the chairman. When on this subject it might be worth while to give the opinion of a prominent Canadian manufacturer who was in Ottawa within the last few days. The manufacturer in question stated that he was going to tell Sir Joseph personally the same thing. Speaking to your correspondent he said: "Our firm has a great deal to thank the Imperial Munitions Board for. I have gone to the chairman several times with propositions that I couldn't see daylight through and I have never come away without the solution of my trouble or something pretty close to it. I believe that I should give credit for the assistance that we have received in this way."

Absorbing Labor

The Imperial Munitions Board had a request from a lumbering concern in the north asking if that board had any objections now to its taking men from shell shops for bush work. The Board replied by wire that if the lumber concern were able to do this they would be helping very materially in bringing about the very end that the Imperial Munitions organization has in sight.

American Contracts

While the British business is done for—or at least will be within a few days or weeks—there is not such certainty about the termination of some of the American contracts. The production of the 240 mm. shell may be continued.

The guns for these shells are being turned out now in United States shops; the Motor Trucks Ltd., of Brantford, have a contract for 250,000 of these shells. The shell differs from the old 9.2 as it has quite a taper from about half way up the body. The U. S. government wants these shells, and it may be that firms holding these contracts will be making shells when the business in other centres may have become simply a memory of good wages and quantity production. Of course there's nothing official about this, but it looks probable.

J. B. Detwiler, president of Motor Trucks, was at the Chateau for a day or so at the week-end. He went from here to confer with some of the directors in New York City, and it may be that something definite will be announced shortly.

Motor Trucks have a large shop in Brantford, and it may continue after the war work is done. CANADIAN MACHINERY discussed this point with Mr. Detwiler. "We have a shop there that is certainly something more than a shell shop," he stated. "It is 700 x 90 feet, and it was finished in 45 days from the breaking of ground. It is a steel structure and fitted for other lines than the production of shells. I am not able to state just what lines I refer to, but we have plans that are fairly well advanced in this direction. Production has been held back with delays in installing equipment, and more especially with power shortage. We are equipped for group motor drive, and it is only recently that we have been able to secure anything like sufficient power for some of the heavy initial operations."

The Position of Labor

The next few months is likely to require a considerable amount of common sense on the part of both employers and employees. CANADIAN MACHINERY can state definitely that the Labor Department does not anticipate trouble if this condition can be brought about, and there are many indications that point to it as a real likelihood. Senator Robertson, the newly appointed Minister of Labor, has a grasp of the situation. He came from the ranks of organized labor, and it does not require much conversation with him to impress upon one the fact that he sizes up like a good go-between for both capital and labor. He discussed the situation at some length with CANADIAN MACHINERY, and his views are those of a man who has been a keen student of the situation, well versed in the contributory causes to trouble and their cure, and firm enough to have a solution for them.

"I have no reason to anticipate serious trouble, although we realize that the demobilization of the army, following hard upon the cancellation of war contracts, is going to give the country a real problem to deal with. Against that I am firmly convinced that we have a more conciliatory spirit on the part of both employers and employees than has been the case for some time past. The employer of to-day, especially the younger generation, realizes in a very direct way that they have a greater responsibility to the man in their shops than simply to extract a day's work from him, and the men are coming to see that their success is very closely connected with the success of their employer. Then there is the softening influence of the war. It has played its part. It may not be apparent on the surface, but it is there, and it is going to be felt.

The Demobilization Plan

"The manner in which the army is going to be demobilized is going to prevent, as far as possible, the congesting of the labor market in any one particular section. For instance if you take ten thousand British Columbia men and put them back in British Columbia, and ten thousand Alberta men in Alberta, and so on, you are going to have a much more equal distribution than had you taken that ten thousand and unloaded them at some of the ports, either at Halifax or Quebec.

"If there is going to be a pinch it will probably come in the first four months of the year. We are facing a situation where, above all else, we have a right to demand from all classes, moderation, and a large measure of conciliation. Give us that, and we have little to fear."

Officials in close touch with the Labor Department believe that a lot of foreigners will be leaving Canada very shortly. One of them put the case to CANADIAN MACHINERY this way: "As soon as an Italian gets about $2,000 in his belt he buys a ticket and goes back to Italy, and he is fairly well fixed for some time to come. These men have not been able to get back for some time, and when I refer to that I mean others than Italians. They have in many cases during the last four years made more money than they ever dreamed was possible. As soon as shipping is available they are going to leave. They will take quite a lot of money with them, but lying in their money belt is equivalent to having it withdrawn from circulation. So my parting word to them would simply be, "We'll never stop you."

MASSEY-HARRIS WANT 100 MOLDERS, THEN 1,000 MEN

THAT the securing of one hundred molders right now means the employing of 1,000 men in the shops of the Massey-Harris Company is the information given out there to-day. The Massey-Harris Company is starting an advertising campaign to secure these men. They are using space liberally. Here are some of the advertising notices that state the case from the company's point of view:

Food For Thought!

What does the future hold for you, Mr. Worker? Why worry when prompt action may get you a steady position in the largest peace industry in Canada?

MASSEY-HARRIS CO., LTD.

Notice To Factory Workers

Now that peace is in sight you will wish to consider permanent employment. Never has the demand for food been so urgent. Why not help us to increase production by working in the Massey-Harris factories? Ideal working conditions.

Massey-Harris Co. still have room for more molders as the demand for implements is urgent. Why not secure steady work at the highest wages while you still have the opportunity?

Mr. Gifford, superintendent of the Toronto plant, in discussing the matter with CANADIAN MACHINERY, stated that their policy would be to keep up the wages as long as possible, and so secure the cream of the men that would be desiring employment. "A few men dropping in and asking for work in the last few days is the first sunshine that we've seen in a long time," he stated. Ten of their old molders are back with them again.

In some cases molders have quit their trades and entered war contract shops for the higher wages that were being paid there. In that they have acquired a liking for machine operations, and seek them when they apply at places like Massey-Harris. However the chance of making around $6 per day, with steady employment, is quite a factor in making them molders again.

Officials at the plant stated that there was a tendency on the part of some who had been laborers before to hold out for something better because they have been making big money in munitions plants, and they do not like to fall back to the laborer's rate of pay. The prospects of steady work through the winter have considerable to do with a decision, though.

Hamilton Industries In Good Shape For It

Interviews With Large Number of the Industrial Leaders Gives Reason to Hope For Continued Employment—How War Shops Are Turning to Other Lines Now

Special to CANADIAN MACHINERY

HAMILTON, Nov. 19.—The forecasts made by economists that a period of industrial depression was bound to follow quickly on the heels of the termination of the European conflict, are not going to materialize so far as the numerous large industrials of Hamilton are concerned.

Not that the heads of these concerns think there will not be a period of grave re-adjustment to be carefully weathered. But they are prepared for the transition that must soon come, and ventured the opinion collectively that there would be enough foreign orders to keep the wheels of industry humming for many months to come, to say nothing of the large volume of domestic business which is looked for.

Shut-downs are not looked for at all, and while in a few isolated cases war workers may be thrown upon the country for a short time, and the reduction of the Canadian army may do likewise, Hamilton manufacturers rather lean to the opinion that all this available labor will be absorbed quickly.

It was frankly admitted by several of the more prominent manufacturers that the Imperial Munitions Board would in all likelihood entirely cancel its contracts within the next few days, but no alarm is felt at that, because, as has been mentioned, all preparations for placing factories on a peace basis have already been made. Nor does this imply that wages will decrease. The labor market is still acute and is likely to remain so for some time to come. More than a few Hamilton industrials reported that they could all do with two and three hundred more men each, and were willing to pay current wages. Die sinkers and machinists are most in demand.

As for foreign business, there appears to be plenty of it in sight. A heavy demand has been created for machine tools in foreign countries, all the belligerent nations included. Much rollink stock is also wanted, while South American nations have placed large orders for agricultural implements with four Hamilton concerns.

It might be said here that the labor market is causing concern if anything. Many manufacturers predict that once the present scarcity of shipping is relieved—as they expect it will be another twelve-month hence—hundreds of foreigners who worked steadily during the four years of war for the highest wages they ever earned in their lives, will flock to their native lands with pockets filled with gold. The question which causes worry is: "From where will albor be recruited to make up for this shortage?" Meanwhile, there is every promise that Hamilton, industrially speaking, will pass through the period of readjustment without any depression. Fully thirty or thirty-five thousand industrial workers are engaged at the present time, and this huge force will be increased if anything.

An individual canvass of the larger industries tends strongly to confirm the general viewpoint. Especially large orders for all kinds of equipment have been received from Belgium and France, and now that the submarine menace has ceased, export business will gradually revert back to normal, and orders which have not been delivered on this account will now be forwarded.

The largest industry in Hamilton is the Steel Company of Canada, which employs 2,900 men, and which has been working steadily on war work since the outbreak of hostilities. The company's contracts with the Imperial Munitions Board would ensure it remaining on war work for many months to come, but it is felt that these contracts will doubtless be cancelled at an early date. Loss of this work will cause not even a temporary lull in the operations of this plant. Francis H. Whitton, general manager, stated that, while the company was necessarily uncertain at present as to how much longer it would continue to produce war material, there was no uncertainty regarding future orders.

Much Depends On Railways

"We are working on war orders at full blast at the present time. If the war work is stopped we will revert to our other orders which include equipment for foreign countries. We have considerable domestic business in sight also," stated Mr. Whitton, who added that the railways were all in need of rolling stock, which meant heavy castings, etc., while the government would no doubt start many public works. Mr. Whitton said it was imperative to the stability of conditions in Canada that railways keep things moving. If transportation was not adequate to the new demands then it would be very difficult for large industrials to carry out their programmes.

Mr. Whitton pinned great faith in the ability of the Canadian Trade Commission to procure much foreign business for Canadian manufacturers while it is abroad. He thought that if manufacturers were prepared for the readjustment this commission would see to it that they got all the orders they could handle for months to come.

Mr. Whitton made it clear, however, that no one really knew just what the future held. Many broad questions were involved; but summing the situation up, by and large, he thought it was very promising.

As regards the probable demand for machine tools, Mr. Whitton said the Steel Company of Canada was not purchasing any at the present time. This company is not likely to scrap its munitions machinery.

At The Westinghouse Plant

Paul J. Myler, president of the Canadian Westinghouse Company, which has worked extensively on munitions, when asked what the outlook for his company was, was inclined to be non-commital as he said he was not in a position to talk. Mr. Myler did say, however, that the company had sufficient American orders for electrical equipment to keep it going for the next four months. About twenty per cent. of the output of the company is destined for the American markets in normal times, and no uneasiness is felt. As for the equipment which had been used in the making of munitions, Mr. Myler stated emphatically that none of it would have to be scrapped as it was adapted for such work.

War End Makes No Difference

Although it has worked exclusively on munitions since the outbreak of war the cancellation of such orders will have no effect on the Tallman Brass & Metal Company, and work will continue as usual.

Addison H. Tallman, manager of the company, said that if anything conditions in the immediate future would be better than ever. "We do not look forward to experiencing the slightest difficulty during the readjustment period. There might be a temporary hold-up, but that is extremely unlikely. We have large orders on hand which were held up owing to the shortage of certain material. The ending of hostilities will enable us to get these materials and then we shall proceed with our new business. Our new orders are both domestic and foreign. We expect to be soon able to resume our export trade in brass lines to Australia, Siam and South America. We certainly will not close our plant."

Will Make Steel Barrels

Otto W. Cook, manager of the Canadian Cartridge Company, stated that the end of the war would not affect his company in the slightest degree. One of the largest makers of munitions in Canada, this concern has lost no time in preparing for the period of readjustment, and will divert its efforts into a new channel entirely. Believing that a large market is open in Canada, the United States and other countries for steel barrels the Canadian Cartridge Company has erected a new $100,000 addition to its plant for this purpose and will commence making these barrels early in December. This company will be the only one in Canada to make steel barrels, and the present staff, engaged on munitions, will all be absorbed when the new work is taken up.

"We do not expect the slightest lull in operations. By the time we clean up our munition work we shall be able to proceed with the manufacture of barrels," said Mr. Cook, who added that machinery for the new work was arriving every day.

Men Are Wanted Here

Officials of the National Steel Car Company were very hopeful regarding the future. They said that they had plenty of business in sight and were not worrying in the least at the possible early cessation of munition making.

B. A. Hamilton, works manager of the company, said that the new orders the company had received were chiefly for rolling stock for the Canadian Government and the Malay and Indian governments. One thousand cars alone would be made for Canadian railways controlled by the government. Increased business was anticipated as a result of the visit to Europe of T. E. McAllister, president of the company, who recently returned. The company also thought that the Canadian Trade Commission would be very hopeful to Canadian industrials.

"We are badly in need of more labor, and can use three or four hundred more men and ensure them steady employment for several months to come. We principally want die-sinkers, machinists and car builders," concluded Mr. Hamilton.

At Dominion Foundries

Officials of the Dominion Foundries & Steel were not in a position to say just what the future activities of the company would be. The making of shell castings had occupied the company's attentions for the past four years, but plenty of new work was in sight, chiefly heavy castings and forgings. No shut-down is anticipated.

Not On War Work

Walter B. Champ, secretary-treasurer of the Hamilton Bridge Works Company, said that large orders for shipbuilding material, principally angle-iron, etc., would keep the company busy for many months to come.

"We have large orders for this material from the United States to enable it to carry out its large shipping programme. We also have many orders for construction steel and iron. The company never engaged in war work, strictly speaking, and therefore will not be affected during the readjustment period," said Mr. Champ.

Plenty of Orders

Col. Arthur F. Hatch, general manager of the Canada Steel Goods Company, was optimistic regarding the outlook in general. He hazarded the opinion that two years hence Canada would be the most prosperous country in the world. "Any country that can produce the grain we can, does not need to worry about the future. As for our own company we have plenty of orders on hand. There is always a demand for steel goods, consequently we do not look for any lull in production. We have many foreign and domestic orders."

Tonnage Will Help

C. R. Brown, secretary of the Canadian Drawn Steel Company, said that his company was in good shape. The output of this concern is chiefly agricultural implements and also equipment for shipbuilding concerns. These oredrs will keep the company busily engaged for several months to come, and are destined for Canadian points. Mr. Brown said that the company always did a large export trade until the scarcity of shipping prevented further activity. With the tonnage growing better all the time he said the company's export trade would not only come back to normal, but would doubtless increase, as it was out for all the foreign business it could get.

Officials of the Otis-Fensom Elevator Company, which has worked almost exclusively on munitions during the war, declined to make any statements regarding the industrial outlook of the company, as they said they thought the present time was not opportune for forecasts.

No Trouble Here

A. L. Page, general manager of the Frost Wire Fence Company, stated that his concern has been, and will be, engaged solely on the producing of agricultural equipment and farm requirements. Mr. Page said that the company, having never engaged in war work, did not contemplate any difficulty in passing through the period of readjustment, as it had plenty of orders on hand.

Want Farm Machinery

The Oliver Chilled Plow Company, which also has not engaged in war work, has plenty of export orders on hand to keep it going for a long while to come. Great demands for tractors have come from South America, Australia and Western Canada. Gang plows and all other forms of agricultural equipment are in demand also. "We have plenty of orders on hand for this equipment from South Africa, Great Britain, and other countries already mentioned," said Albert C. Dann, superintendent. This company is also eager to engage many additional workmen. Bench hands, assemblers, forge hands, etc., are wanted.

Busy at International

H. H. Biggert, superintendent of the International Harvester Company, stated that the company had orders for agricultural equipment that would keep it going for the next twelve months, and with the return of conditions to normal, orders would no doubt be increased.

"We have much business for New Zealand, Australia, Great Britain, South America and Italy. We are going full force at the present time and unless something unforeseen happens will continue so for some time to come. There is no possibility of this plant closing down. Every man we have will be kept busy," concluded Mr. Biggert.

Orders of Machine Tools

Regarding the likelihood of a demand for machine tools, officials of the Ford-Smith Machine Company stated that they were figuring on a large demand for this class of work from the foreign markets. The current demand of the domestic market might slacken for a time; but there was no doubt in their minds that much of the munition equipment would have to be scrapped. Most of it was worn out anyway, it was said.

"We have large orders for machine tools from all the belligerent countries," said an official.

LONDON SHOPS READY

Geo. White & Sons Co. Have Lines in Shape—Concrete Machines For Export Trade.

LONDON, Ont., Nov. 21—George White & Sons Company, Limited, and employees, of London, have subscribed $75,000 to the fifth Victory Loan which has just closed. Arthur W. White, vice-president and manager, has been the efficient chairman of the industrial committee of the London Victory Loan organization and to his leadership a great deal of the success of the work among the factories has been due. The canvass was handled by the company, the work being done in the various departments by the different foremen. F. J. White, secretary and sales manager, and E. A. White, treasurer, had charge of the canvass among the office employees. John Vasbinder, superintendent, assisted the foremen in their work. Following are the names of the department heads who did good work among the employees in the canvass: Harry Williams, machinists; William Wood, foundry; John Fryer, boiler department; William Elliott, and William Cooper, woodworking department; William Mason, wheel department; Frank Meanley, engine erecting department.

After-War Conditions

Arthur White says in reference to the conditions of the near future, that his firm is ready to start full blast on the manufacture of farm machinery as soon as it is possible to secure sufficient supplies of raw materials. He anticipates that his company will have a full supply of gasoline and steam tractors, and threshing machines ready for next year's trade which he thinks will be unusually heavy.

He intends going after the tractor trade as he sees a great opportunity in it. The tractor is here to stay and it will not be long until it will be as common as the automobile. The steam tractor is still holding its own with the gasoline tractor, and Mr. White thinks that it will be in good demand.

Export trade is being considered by the company, but it is the intention to supply the home market first. It is anticipated that this market will be so heavy that it will be nearly impossible to supply any goods for export.

Prospects Are Bright

"Prospects are bright for a heavy trade in our line at least," said H. Pocock, president of the London Concrete Machinery Company, to the CANADIAN MACHINERY AND MANUFACTURING NEWS recently in reference to the outlook for business following the war. "Our business has kept up throughout the four years of war and for the first fifteen days of November it has been double that of the corresponding period in any other year. September and October of this year we did the largest business of any corresponding months in any other years."

The London Concrete Machinery Company, H. Pocock, president; J. C. Doidge, vice-president, manufactures concrete mixers of all sizes, and it has recently undertaken to distribute the Novo dust-proof and frost-proof gasoline engines for Canada. This is the engine that is now being put out with the concrete mixers. It is made by the Novo Engine Company, of Lansing, Michigan. It is a vertical engine and all its working parts are enclosed in oil. The manufacturers assert that this feature enables it to give service for three times as long as the ordinary open type engine. It is also lighter in weight per rated h.p. than theh ordinary gasoline engine.

The Export Trade

An order recently has been received by the company for two carloads of cement mixers to be shipped to Australia, two carloads to South Africa, and one car to New Zealand. The company is busy on these orders now.

This company is already making plans to capture some of the export trade in France as it is thought that the demand for its goods will be large there for the next few years. It will have an exhibit of concrete mixers at the Lyons fair which will be held in France in March. Several sizes of mixers suitable for building construction will be exhibited.

Mr. Pocock has no fears for the future of Canada as he thinks the export trade will enable the wheels of industrialism to keep revolving at a sufficient speed to preserve the present prosperity and in time increase it.

WELLAND PLANT IS O.K.

Steel and Metals is in Shape to Manufacture Mining Machinery Now.

WELLAND, Nov. 21—The Electric Steel and Metals, Welland, are actively contemplating the manufacture of mining machinery and other products of like nature. Unlike many plants engaged on war work, this company's equipment is admirably adapted to peace needs. The electric furnace installation and the structure in which the furnaces are located were erected in 1913 to serve the strictly commercial purpose of making steel castings and no change in equipment was needed to adapt the plant to the casting of steel shell billets. On teh coming of peace a few days' preparation will suffice to change from a war to a peace basis and the buildings since erected for shell turning have been built to serve the purpose of a permanent machine shop.

In conversation with a representative of CANADIAN MACHINERY Mr. E. Carnegie, president and general manager, expressed the opinion that Canadian manufacturers have reason to be very optimistic over future business conditions and that a little thought and foresight now would be amply repaid in the permanent prosperity to come.

BELT TERMS DEFINED.

British Cost Is Away Below This Country's

Figures Secured Shows That the Shipbuilding Industry in Canada is Up Against a Very Hard Competition by Reason of the Difference in Wages and Cost of Material

Special to CANADIAN MACHINERY

OTTAWA, November 20.—Under the programme of Canadian shipbuilding authorized by order-in-council last March fifty-five million dollars was to be expended. Up to the date of this article the contracts authorized may be summarized as follows:

Lake type	9	vessels
4,300 ton type	6	"
5,100 " "	8	"
8,100 " "	14	"
10,500 " "	2	"
	39	

As mentioned by Sir Joseph Flavelle in an interview given to this paper this week, the policy of the Imperial Munitions Board will be to push its shipbuilding activities to the limit, and as soon as the berths occupied by the Board's vesseds are cleared they will be occupied by ships to be constructed under the Canadian Government programme.

For some time to come the government work will keep all the yards fully occupied. From the very first the Marine Department has been opposed to the increasing of the establishment of new yards. The steel available has not been sufficient to keep existing yards fully occupied, and the Department felt that the best policy was to keep existing yards occupied to their full capacity rather than to increase the number of yards when, owing to the scarcity of labor and material, they would not be running full time. It was also felt that if at any time in future construction should decline, the same thing would apply

The Matter of Price

The prospects for the future largely depend on how far we in Canada can go in the direction of building ships within measurable distance of what they can be built for in the United Kingdom. This applies to the future of shipbuilding in the United States also, because at the present time prices in the Canadian yards compare most favorably with the prices for ships of the same type in American yards.

At present, ships built in Canada are costing about double what they cost in the United Kingdom. This is due to the high cost of material which, in turn, is due to the high cost of labor, mainly.

Steel plates have been available to builders in Great Britain at a price of, approximately, fifty-five dollars a ton. Compare that with the following schedule, showing the delivered cost of steel per long ton from Pittsburg and Chicago to different points in Canada:

From Pittsburg to	Cost per long ton
Vancouver, Victoria and Prince Rupert	$102.25
Port Arthur	89.37
Toronto	78.84
Collingwood	80.19
Montreal	96.89
Three Rivers	81.87
Quebec	81.87
Halifax	84.67
From Chicago to	**Cost per long ton**
Vancouver, Victoria and Prince Rupert	$100.80
Port Arthur	82 32
Toronto	79.29
Collingwood	81.08
Montreal	99.68
Three Rivers	84.78
Quebec	84.78
Halifax	87.36

So much for the relative cost of materials with ourselves and our great competitors. The next factor is the cost of labor in the shipyards. The following are the wages paid per week to the different classes of shipyard workers in Great Britain and in different points in Canada:

Wages Per Week to Shipyard Workers in Great Britain and Canada, With Per Cent. Increase in Canada Over Great Britain

Trades—	England 50 hrs.	Montreal 50 hrs.	% Inc.	Pt. Arthur 50 hrs.	% Inc.	Pac. Coast 44 hrs.	% Inc.	Pac. Coast % inc. over Montreal
Shipwrights	$16.50	$27.80	68.5	$34.45	108	$36.30	120	30
Joiners	16.50	26.50	60.0	35.77	116	36.30	120	37
Patternmakers	16.50	31.80	92.0	37.00	124	39.30	138	24
Plumbers	16.50	27.80	68.5	34.45	108	33.00	100	19
Blacksmiths	16.05	27.80	73.0	34.45	114	33.00	105	19
Hammermen	13.00	17.50	34.5	35.15	93	24.64	89	41
Painters	16.05	23.85	48.5	29.15	82	20.22	88	26
Machinists	14.40	29.25	100.0	35.75	148	33.00	129	12
Rivetters	15.55	29.15	87.0	35.75	130	33.00	100	12
Holders on	14.15	26.25	85.0	26.50	87	25.52	80	*2¾
Platers	16.05	29.15	81.0	26.50	65	33.00	105	12
Caulkers	15.55	29.15	87.0	35.75	129	33.00	112	13
Electricians	16.50	27.80	68.0	35.77	116	33.00	100	18
Riggers	13.20	23.85	80.0	31.80	141	33.00	150	38
Laborers	12.70	20.00	57.5	21.20	67	21.12	66	5
Engineers	16.09	33.75	110.0	33.75	110	33.00	105	*2
Boiler makers	....	39.25	....	33.75	...	33.00	...	*19
Boiler makers, rivetters	16.50	39.25	137.0	33.75	.100	33.00	100	*19
Boiler makers, helpers	12.40	20.00	61.0	22.50	80	23.65	91	18

*Dec.

Approximate Increase—
Montreal over England 80%

Port Arthur over England 108%
Pacific Coast over England *110%
Pacific Coast over Montreal *15%

*Not allowing for lower number of working hours.

Needless to say, if private capital is to be invested in the purchase of ships, they will buy in the cheapest market, and cost of building being about the same here and in the United States, the competitor of both countries will be Great Britain. If the industry is to expand, or even continue to the same extent as before the war, it is apparent that it can do so under one of two conditions: wages must come down in the steel making and shipbuilding trades, or the industry must be helped by some system of bonuses or tariff protection.

Before the war a common objection to the feasibility of building ships here was that we did not have a supply of skilled labor. That objection has, to a large extent, vanished. A large body of skilled labor has been trained here during the war. As a matter of fact there is nothing very intricate or technical about the majority of the operations in building a ship, and the time required for men to become reasonably skilled is not long.

The immediate policy of the government in regard to the industry will be to fill up the present berths as they become empty, and, so far as can now be seen, this will continue for an indefinite time to come.

NOVEL ENGLISH SPEED REDUCTION GEARS

By F. C. P.

The English speed reduction gears shown in the accompanying illustrations were designed at Willesden, London, England. These reduction gears are constructed on the epicyclic principle, having sun and planet pinions running in oil and enclosed in a cast-iron dust-proof case. The pinions are cut from solid steel blanks by special machinery and bushed with phosphor bronze, and the pins on which they turn are all carefully case-hardened.

There are oil grooves cut, along which when the gear is running the oil is forced into various bearings by centrifugal force. For large power gears running at high speeds an oil cooler is attached and the pinions are frequently cut from special high quality nickle steel.

Owing to the efficient system of lubrication, and to the special shaping of the wheel teeth, a very high efficiency is obtained with this gear, 90 per cent to 95 per cent being obtained, and this efficiency unlike that of most other forms of gear, is found to be lasting. Instead of the load being transmitted through one point of contact, as in most gears, it is divided between three points simultaneously, thus greatly reducing the pressure between individual teeth, and consequently the friction and wear.

It will be seen that by varying the size of the pinions, it is easy to construct a gear to give any required reduction, there having been developed gears of from 3 to 1. 2.000 to 1 reduction. The slow shaft at one side of the gear is in a straight line with the fast shaft entering on the other side. It is often a very great convenience to have the drive in a straight line with the engine or motor shaft as in these gears. A friction clutch is provided in the gear which allows the engine or motor to be started without any load on, and when started, the load may be gradually applied by means of the clutch.

It may be stated with regard to the life of the gears that there have been several cases in which they have been running for 7 or 8 years and a number running in the Willesden Works for driving line shafting and machines from electric motors for 8 or 9 years, the original wheels being still in use.

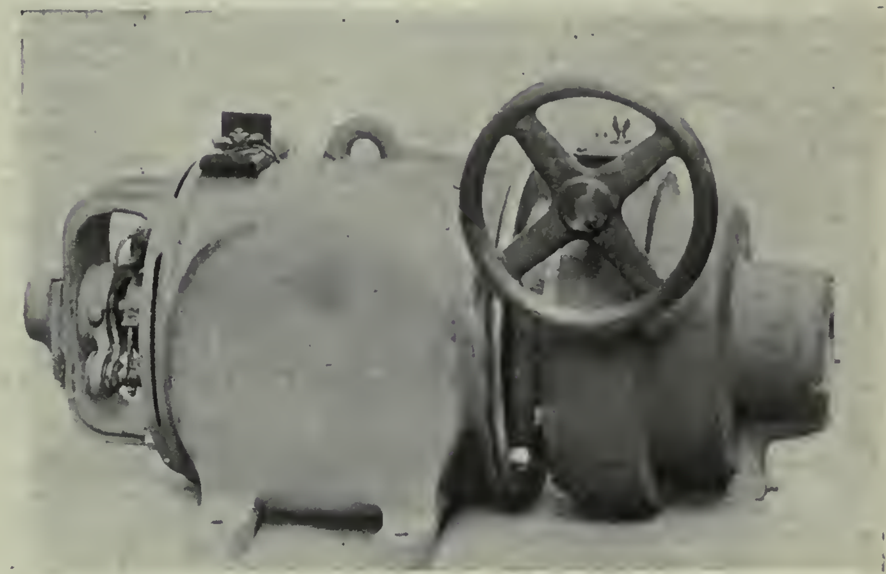
The advantage of the direct electrical method of driving machines in almost all kinds of manufactories is now very generally admitted, it permits the machines to be placed in any position and does not restrict them to the line of the shafting; they can be placed in out of the way positions far away from the source of motive power; the very heavy losses due to belt slip and friction on line shafting and counter shafting are avoided. Finally and perhaps more important than all others is the advantage that where each machine has its own motor no power is being wasted during the time that the machines or some of them are standing idle.

It is claimed that one difficulty which has stood in the way of the application of the electrical drive has been the high speeds at which electric motors of low and medium powers run, and the inefficiency of the ordinary means employed to reduce these speeds to those of the driven machines. In many cases where the driven machines run at low speeds as much energy is absorbed by the gearing or belt transmission as would suffice to drive the machine. Counter shafting with the necessary belting takes a great deal of room and is constantly requiring attention and even then the loss of power due to friction and belt slip is very considerable. Worm gearing if carefully constructed for low radius of reduction is fairly efficient while new, but wears very quickly, and is then, and when employed for high ratios of reduction, notoriously wasteful in power. Slow speed motors can be obtained, but are necessarily very heavy and very costly.

Another difficulty which applies especially to places where alternating current is used is the difficulty of starting up the motors under load. These difficulties are entirely overcome by employing speed gears for coupling the electric motor to the driven machine.

This gear is an adaptation of the epicycle principle, spur wheels and pinions being used throughout arranged to distribute the driving force in the gear as to reduce the pressure between the teeth of the gear wheels as much as possible, thus ensuring high efficiency and reduced wear. This is accomplished by always having a large number of teeth of the wheels in mesh and dividing the load between certain number of points in the gear, two in the low ratio gear and three in the higher.

It will be seen that the sun and planet wheels run in oil, and are carried in a cage upon which centripetal grooves are cut, which distribute oil under pressure to all bearings, and the gearing, being cased in, is thoroughly protected from dust and dirt. The teeth of the wheels are very accurately cut by special machinery from steel blanks, and the wheels are suitably bushed. In special cases nickel steel pinions are used.



ENGLISH SPEED REDUCTION GEAR ATTACHED TO MOTOR

This gear is noiseless and very compact. It is usually fitted on an extended bedplate with the motor. These gears with any ratio up to 30 to 1 can be used to increase speed instead of reducing by working from the opposite end of the gear. In this form they can be successfully employed to couple slow-running engines to dynamos. Most reductions required for any commercial purpose can be obtained in a very small space.

There are a great many of these gears in use for mining haulage work, stamps, elevators, pumps, line shafting, conveyor bands, mixing machines, gas blowers, and for numerous other purposes where the speed of the driven machine is comparatively low.

Views and Opinions Regarding Industrial Developments, Factory Administration and Allied Topics Relating to Engineering Activity

CENTERING TOOL FOR DRILLING CONCENTRIC HOLES

By D. A. Hampson

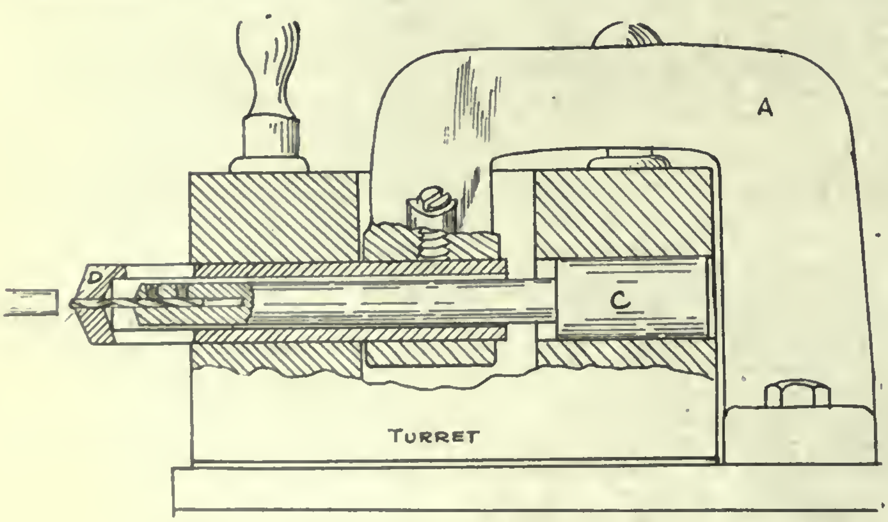
ANYONE who has done automatic screw machine work knows of the necessity for centering if a concentric hole is to be produced. At times a set-up may be so involved that there is no chance to use a centering tool in any of the turret holes; then various devices are resorted to which put in the center by a combination of turret and cross slide movements actuating an auxiliary tool; again, no center at all will do if the drill is large and has but a short extension beyond the holder. But if there is no way to get in a center and the drill is small and must enter the work a considerable depth, then a breakage of a dozen drills an hour must be expected and a large number of eccentrically drilled pieces will result.

If not pushed and with a machine in first-class condition, an operator can keep the severed end of the bar flat; against this flat end a small drill will usually start true if a light feed is used. but given average conditions and we find a suspicion of a raise or teat on the bar end which works havoc with the drills.

We had a ½-inch hand screw machine that had been rigged up to work automatically, that used but one of five holes in the turret and as a consequence was not made to revolve the latter. The machine did well on plain work. Unexpectedly, it was necessary to put the machine on a steel piece that had a 1-16-inch hole ¼-inch deep, and it was impossible to arrange any centering tool. The device shown by the drawing is how the work was done successfully with but little drill breakage.

A yoke shaped piece A was fastened to the turret saddle reaching over inside the turret and holding the guide D, sliding in the forward hole and having a hardened end to guide the drill. The guide D is drilled out almost its entire length and in this space there extends the drill holder C, carrying the drill at its forward end and secured to the turret at the rear end. Slots in the free end of D give access to the screws holding the drill and permitting chips to fall out below.

The guide is set an eighth of an inch away from the work; it remains in one position all the time but the drill passes in and out according to the camming of the machine. The hole at the rear of the turret secures and moves the drill instead of the front hole as usually done. Operation was quite satisfactory, the drill in effect being guided as in a drilling jig.



SET UP FOR DRILLING CONCENTRIC HOLES

STRAIGHTENING HARDENED PIECES BY VARIOUS METHODS

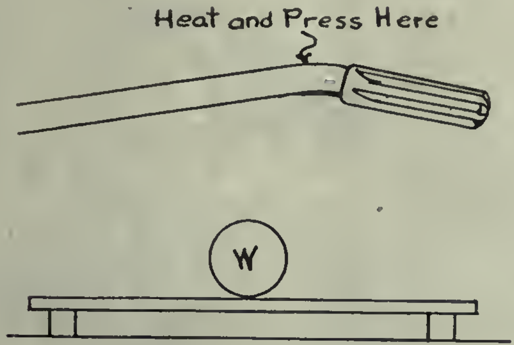
By D. A. Middleton

All machinists know in a general way that tool steel pieces that have been hardened can be straightened. But in trying out the method—heating the part and springing it in the direction it should go—there have usually been disastrous results. I have seen 1-inch arbors that had got bent put in the lathe and forced over by a piece in the tool post and about the time they assumed the desired shape, they snapped like so much glass. Breakages will occur—do occur even in plants that make drills and reamers and have experienced straighteners at work all the time—but if the principles are understood and care exercised there is no reason why much crooked work cannot be straightened and represent a big saving for the shop.

It must be understood that freak bends belong in another class. A piece 8 inches long with an inch of bend cannot be straightened—here the trouble is ignorance or carelessness on the part of the hardener or it has originated from lack of knowledge as to working the steel in the machine shop. But supposing a special rose reamer for a ¼-inch hole has been carefully made up and tempered and when put on the centers it shows a bend of a sixty-fourth—that can be straightened very easily.

Heating

The heating is done in a variety of ways according to the shop equipment and the nature of the crooked piece. A "hot plate" is often the medium for flat pieces, a Bunsen burner or ordinary gas flame or an alcohol torch serves very nicely in other cases, and even the forge fire can be made to answer when the piece is large. One would naturally think that as the hollow, or concave, side of the crooked piece has to stretch out in straightening that that side would be heated to take advantage of the expansion that occurs with a rise of temperature, but such is not the case—the heat is always applied to the "high" or convex side.



EFFECTS OF HEAT AND PRESSURE.

SMALL PRESS FOR STRAIGHTENING

Gauging the Heat

If the part being straightened has been polished, the workman can tell when the limit of heating has been reached by the appearance of the lightest straw color; in most cases this will be the limit, though in others the natural working state of the part may correspond to a blue and in such cases any color up to the blue will do no harm. A good way to gauge the heat is to put a film of oil on the concave side, then when this begins to smoke, it is a sign that the temperature has risen several hundred degrees and the work is ready to spring. Various oils have different flash points, so if desirabble they can be roughly calibrated and used according to the different tempers in different work pieces. A point in favor of the oil method appears when the work cannot conveniently be polished or when the flame is of a discoloring nature.

Making the Bend

Having brought the work up to right heat, the greatest heat at greatest bend, it is transferred quickly to some sort of a straightener or to lathe centers. With a portable source of heat, the heating is done with the work already in place. Selecting the point of greatest bend, pressure is applied on the high side, springing the work until it bends the other way. By holding the piece so, as it cools, a permanent set is acquired. It is possible to overdo the spring and bend the piece in the opposite direction—experience, good judgment, and trial will tell how far to carry this; skilled men seldom have to re-heat a piece.

Pieces with centers in may be handled in a lathe. In lieu of this, the small bench straighteners on the market are supplied with centers and these are the most convenient means of straightening rectangular shaped pieces. Slender pieces may be held by pliers in each hand. Another way is to weight the part that has been heated. A shop that had quite a variety of this work to do—largely flat and square-made cast iron straighteners, very simple and cheap, and as the work was all delicate, a ⅜-inch thumb screw furnished all the "power" necessary and was a safeguard against too much springing. The lathe and the straightener have been disastrous in so many cases because "a man gets too strong" when using them.

Prevention has always been better than cure; applied to hardening, much of the warping and crookedness can be avoided by proper heating and dipping. It is generally known that long pieces should be dipped straight down—sometimes they are suspended from a string to insure this. When a piece is held at angle and plunged, it cuts a path through the water which cannot close quickly enough to give the same intimate contact on the back as on the leading side, with a result that the leading side cools first and contracts, giving it a concave form which necessitates straightening. In some kinds of work this may be taken advantage of and forms a trick of the trade—as in file hardening where the back of a half round has more surface than the flat side and consequently contracts more if dipped straight, but the hardener overcomes this by dipping the file at an angle.

SLIPPING OF BELTS

By M. E.

Belts, when running slowly and transmitting little power, may run a considerable time without giving evidence of slip, but when running at recognized speeds for the transmission of power, the slip may be considerable, although it is hardly a subject for calculation. Many factors may enter into the causes of slipping, slackness being the most important. Slipping, once begun, may polish the inner side of the belt and reduce its adhesion. A layer of air is said to enter between a high-speed belt and its pulley, serving as a lubricant and reducing adhesion. As a remedy, perforating the pulley with holes has been tried, but without definite results. Centrifugal action has also been suggested as a cause for slipping; but, when reduced to calculation, the centrifugal of a piece of belt x weight running at w speed round a pulley by radius would be a very small amount compared with the united pull of the driving and returning sides of the belt. There is another consideration, usually neglected, that may account for what might be called the permanent slip of all belts that are to any degree elastic. The driving and return sides of a belt work under different stresses, and as it passes from driving tension to return tension it is altering in length to the measure of its elasticity. When entering on the driven pulley it travels partly round before meeting the pull of the driving side, which takes place before it reaches the point of release. It is here that the belt is stretched and the permanent slip or creep takes place, which, in every elastic belt, is unavoidable. A properly adjusted steel belt should be free from this peculiarity and should ensure an accurate transmission of speed in all machines except those in which the respective revolutions of axis bring about fixed recurrent relations as in clockwork. Irregularities of belt transmission arise from dirt adhering to the pulleys or to the belts, and also from the action of heat and moisture. All belts and cords contain some moisture, and any increase or decrease of this moisture affects their length. A leather belt shortens on drying and elongates on becoming wet. Hair has the same property as leather, and this property is utilized in the hair hygrometer for measuring atmospheric humidity. Cotton cords and belts, on the contrary, shrink when moistened and elongate when dry. This is due to the alteration of the thickness of the fibre which, when twisted either in woven tissue or cord, swells and alters the angle of twist, causing contraction. Air may hold a great deal of moisture in suspension but, if hot enough, it can absorb more, and thus an oppresively hot and moist atmosphere is still capable of drying and slackening driving ropes and bands.

THE MINIMETER FOR FINE MEASURING

By FANK C. PERKINS.

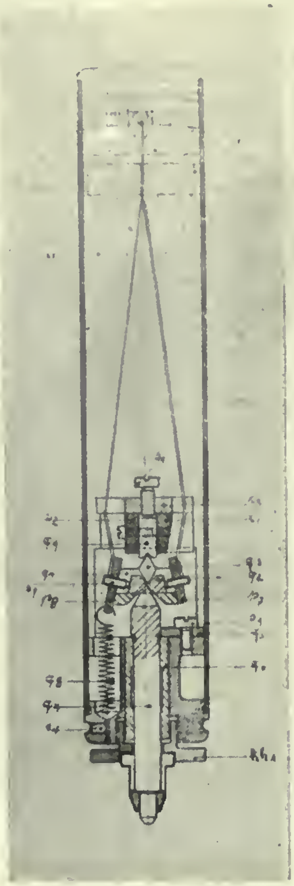
THE accompanying illustration shows the various forms of minimeter of the Hirth design for measuring threads, balls, cylindrical parts and grooves, also for inside measuring of various diameters. It is claimed that there has been a revolution in fine measuring since the war as the greatest care and precision has been necessary in the manufacture of guns and shells.

The development and progressive specialization of modern machinery and the wholesale manufacture of same, necessitates the interchangeability of parts, thus demanding the most perfect measuring instruments. The ordinary rule, caliper gauge with vernier, the feeler, and the deoth gauge, are only sufficient for approximate measurements. Micrometer screws serve for fine measurements and are adjusted on valuable and sensitive measuring instruments.

The construction of the micrometer is well known. It allows gauging to within .0005 of an inch, but its use requires the practiced hand of a skilled workman and, in spite of various improvements, two persons seldom obtain the same result in measuring the same part. The wear of the anvils, the spring of the shoe and the play of the screw, which needs lubrication, are the causes of many errors in taking measurements. The measuring limits of a micrometer are also small, as long screws cannot be made sufficiently accurate.

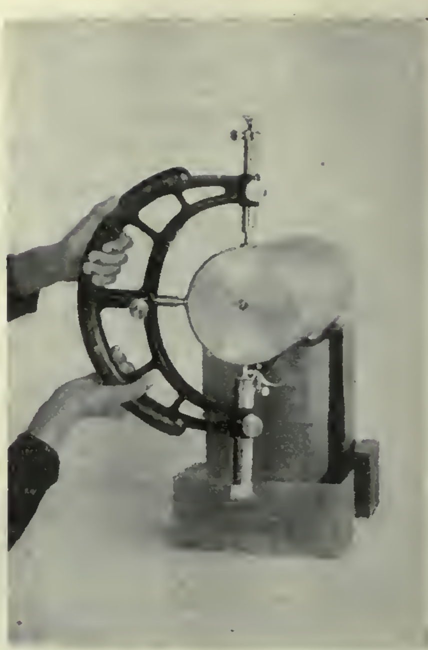
For absolutely accurate measurements only measuring machines can be taken into consideration. The German machines made by Reinecker and various American machines vary considerably in their methods of exact adjustment, but are in principle more or less large micrometer gauges. In both type of machines the measuring disc is divided into thousandths round its periphery, but .000005 of an inch can be read on the vernier. This fine graduation, however, is only useful when the screw is employed in short lengths, that the error arising from same may be neglected. It is therefore necessary to adjust by means of limit end gauges by steps of one inch or, when most accurate measurements are required, in stages of not more than .25 of an inch.

MINIMETER WITH STAND FOR MEASURING THREADS UP TO 80-MM.



SECTION THROUGH MINIMETER

It is true that the instalment of a fine measuring machine and the sets of end gauges which accompany it involves heavy cost, and its use requires much experience. Such a machine is therefore practically limited to the works testing room and may only be used to adjust the limit gauges. The latter are really the actual measuring gauges used in manufacturing and it is a well known but deplorable fact, that they very soon lose their accuracy through wear. Their maintenance is accompanied by large and continual expense, but their greatest drawback is that they are useless except in practiced and skilful hands and only register if a dimension is too large or too small, leaving the amount of error unknown, thus giving the limits of error an unsafe and unsatisfactory character.



MINIMETER WITH HOLDER FOR CALIPERING CYLINDRICAL PARTS

The completion of the work can therefore only be carried through with great care and considerable loss of time by constant measuring and checking.

The fine measuring instrument known as the Minimeter illustrated, it is said, avoids all the drawbacks by its original and simple construction and enables this class of work to be revolutionized. The principle of the Hirth Minimeter consists of a lever having unequal arms carried on knife edges. The use of a double system of levers and bearing pins being discarded, oil films and all play are entirely avoided, thus doing away with the causes affecting precision of apparatus. A longer or shorter distance between the points of support of the lever allows a variation of travel of the indicating hand, whilst the length of the latter remains the same, thus permitting of any given ratio of lever arms to be used.

There is a spring which holds the lever on to the knife edges and keeps it in its normal position when out of use. The whole appartus is screwed into a tube with a glass covered opening at its upper end, showing the graduated dial, bearing the proportion of the lever arms (1:100, 1:200, 1:500, 1:1000), and above which the hand of the lever moves. All the working parts are made glass hard.

The photographs show a complete instrument in actual service. The clamp holding the minimeter slides up and down, thus allowing the minimeter to be set very quickly by means of the screw behind the head of the minimeter, and is locked by the two clamping screws at the side. The adjustment is made by means of two standard gauges. The two rests supporting the part to be measured, consist of two hardened and ground cylindrical rods, so that any wear on the rests does not interfere with the accuracy. The clip holding the rear rest can be adjusted for various diameters of work according to the scale, which can be seen in the illustration. The scale has proved itself a great time saver in adjusting and measuring various sizes of work. The end of the measuring pin is made semispherical, but can also be made conical, if required. The lever at the lower end of the minimeter enables a light finger pressure to raise the measuring pin and thus allows free introduction of the part to be measured, avoiding premature wear on the rests and permitting the measurements to be taken rapidly.

In the minimeter for measuring larger dimensions, the construction of the lower end of the shoe allows a fine adjustment of the instrument, by means of a fine threaded screw, which is locked by two milled nuts. The shoe is held in a wooden socket which closes on hinges.

It is pointed out that by the arrangement for surface measurements, they can be readily taken and the platform or table can be quickly moved within certain limits, by means of the screw underneath. The minimeter holder is in the form of a double clamp and allows horizontal or vertical adjustment over a large field.

Besides the minimeters above mentioned, arranged for outside measurements, the difficult matter of inside measurements has been considered and an absolutely exact, useful and rapidly operated instrument has been made. Until recently one has had to be satisfied with plug gauges and micrometers, which give doubtful results with small bores. An important step in this direction has also been made in the minimeter for this purpose, which is a well-thought-out arrangement for inside measuring of small parts.

The diameter of a circle being given by three points of contact, two fixed ball points are arranged on the cylindrical measuring head, whilst the third point is attached to a lever, borne on knife edges. This lever is in contact with the arm inside the casing and causes a proportional deflection of the indicating arm in the manner previously described, if this arm is pressed. The horizontal contact pins serve as side stops for the measurement of rings. This apparatus can be used for measuring various diameters, by changing the measuring head.

In the special arrangement for measuring inside rings, the minimeter is fastened in the upper sleeve and the three surfaced stops, which are let in, form a rest exactly at right angles to the axis of the ring. The two slots allow for a wide range of varying diameters. It may be stated that inside measuring instruments in various sizes up to 40 inches diameter are available by means of interchangeable rods.

MINIMETER WITH TUBE FOR INSIDE MEASUREMENTS BETWEEN 175-150-MM. AND OF LARGE DEPTHS

PRINCIPLE OF MINIMETER

THIN VERSUS THICK BELTS

By Mark Meredith

In a recent conversation with a man whose experience entitles him to respect the subject of belt life and endurance was broached. The individual in question has pretty definite convictions on the subject, and explained that he would not give double belting house room. He explained that unless the pulleys were of inordinate size the internal stresses in the belt by flexure and repeated bending wore them out in a very speedy manner. His solution is increase in pulley width and decrease in thickness; indeed, he goes further and says that even where pulley width cannot be increased it is quite as economical to use a thin belt, it will last as long. Interpolating as to belting of the Hendry type where the thickness can be anything desired, I was informed that this type of belting was ideal, but it was best not too thick.

As practical instances of what could be done at a pinch in an emergency, a neighboring factory shut down by the main drive belt repeatedly breaking, was got going again by teh use of stout roller toweling purchased at the local drapers. I was invited to see the belting in use in the particular shop, and also that in the stores; it was certainly all single, and even so, thinner than ordinary. The pulleys driving various tools and machines were all criticised on the ground that speed cones were invariably too narrow, that is from my friend's point of view.

Although much has been written first and last on the subject of belting, the particular point elicited here does not seem to have been made permanent. Leather can be had single and double, and there are processes of tanning which plump out the substance to obtain the greatest weight from the original hide. Indeed, for years past the proverb, 'there is nothing like leather," needed revision, for steady deterioration has been a universal experience. In judging, therefore, between rival offers accompanied by small samples, it needs caution, for the best color and substance is by no means the best article. The belt running over small pulleys, as in a high-speed sensitive drill, which stretches like elastic and grows thinner and thinner at each take up, is by no means uncommon, and perhaps the conditions in this instance are the worst possible. It is equally certain that a thick belt on a small pulley has no more adhesion than the thinner type, and slippage means speedy destruction. If for unavoidable reasons the width of the pulley must be limited, and the belt thickness increased to stand the load, the pulleys must be as large as possible.

The same facts apply to balata. This can be obtained 3, 5, 7, and 9-ply, the latter unusual, but provided that the belt is narrow there is no reason why the thickness need stop here. The limiting factor is the width canvas can be woven. My informant, whose opinions are entitled to respect, believes in thin belts of adequate width. He has given much attention to the subject first and last, and the unsuspecting belt salesman who calls for the first time is apt to be crestfallen at the result of the interview. My reason for relating the foregoing is that, from personal experience I am inclined to think that many machine tools have stepped pulleys too narrow on the steps. Where conditions are good it is really wonderful the length of time that a piece of first-rate belting will endure; it reaches a dozen years in some instances, a length of time which may cause surprise in those quarters where belting costs are a disproportionate annual expense.

STANDARD SPECIFICATIONS FOR BABBITT METALS

THE American Society for Testing Materials, at its annual meeting at Atlantic City, N.J., June 25-28, 1918, proposed the following specifications for babbitt-bearing metals, designated as grades Nos. 1 to 12:

TABLE NO. 1—FORMULAS.

	Copper Per Cent.	Tin Per Cent.	Antimony Per Cent.	Lead Per Cent.
No. 1	4.5	91.0	4.5	....
No. 2	3.5	89.0	7.5	....
No. 3	8.33 1/3	83.33 1/3	8.33 1/3	....
No. 4	3.0	75.0	12.0	10.0
No. 5	2.0	65.0	15.0	18.0
No. 6	1.5	20.0	15.0	63.5
No. 7	...	10.0	15.0	75.0
No. 8	...	5.0	15.0	80.0
No. 9	...	5.0	10.0	85.0
No. 10	...	2.0	15.0	83.0
No. 11	...	....	15.0	85.0
No. 12	...	....	10.0	90.0

TABLE NO. 2—PHYSICAL PROPERTIES OF METALS.

	Deformation of Cylinder 1¼" diameter, 2½" high at 70° Fah. in.			Melting Point. Degrees.	
	At 1,000 lbs.	At 5,000 lbs.	At 10,000 lbs	Fah.	Cent.
No. 1	0.0000	0.0010	0.0150	453.2	234
No. 2	0.0000	0.0015	0.0120	460.4	238
No. 3	0.0010	0.0045	0.0070	462.2	239
No. 4	0.0005	0.0025	0.0090	365.0	185
No. 5	0.0010	0.0030	0.0090	.....	...
No. 6	0.0015	0.0050	0.0180	.....	...
No. 7	0.0010	0.0050	0.0230	464.0	240
No. 8	0.0020	0.0090	0.0630	469.4	243
No. 9	0.0040	0.0120	0.0840	469.4	243
No. 10	0.0010	0.0100	0.1540	471.2	244
No. 11	0.0010	0.0100	0.1190	474.8	246
No. 12	0.0025	0.0170	0.2850	474.8	246

The society wisely refrained from recommending these formulas for any special purposes; confining themselves to the statement that "these specifications cover the range of alloys commercially used."

It is regretable that these tables do not also give the coefficients of friction as this information would have been perhaps the most useful aid in determining the relative values of these twelve bearing metals—especially if tests had been made with water lubrication. But the society has made a good start and doubtless they will give these frictional coefficients at some future time.

However, the data furnished in these tables is useful for purposes of comparison, and the object of this article is merely to point out certain facts in connection with these figures that may have escaped general notice.

Many users of babbitts, especially those required for heavy duty, are very careful to specify "copper-hardened" metals, and certain manufacturers of babbitts, knowing this pedilection, boost copper-hardened products. In this connection we call attention to formulas Nos. 3 and 8, given in above tables.

No. 3 is a tin base metal and contains 8 1-3 per cent. copper, the highest percentage of copper in any of these formulas. This composition, under 1,000 lbs. pressure per square inch, compressed to only 0.0010, or one one-hundredth of an inch, and its melting point is 462.2° Fahr.

No. 8 is a lead base metal, which contains no copper, under pressure of 1,000 lbs. per square inch, compressed to only 0.0020, or two one-hundredths of an inch, and its melting point is 469° Fahr.

The difference between these two alloys under 1,000 lbs. pressure per square inch is only one one-hundredth of an inch, which is in width about equal to a line made by the stroke of a hard lead pencil, and the same relative difference between these two metals is maintained at 5,000 lbs. pressure per square inch.

As to the melting point of these two alloys, the lead base metal has the better of it by about 7° Fahr.

When you consider that the tests shown in Table No. 2 were made by compressing a small cylindrical-shaped block, and that in actual use a babbitt metal would, in most cases, be supported by a backing and further bolstered by recesses, the difference in sustaining powers between a tin base copper hardened metal and a lead base metal is practically nil.

Table No. 2 also gives a good illustration of the influence of lead in tin alloys, as shown by No. 4. This composition contains but 10 per cent. lead, yet this small quantity was enough to reduce the melting point to 365° Fahr., which is about 5° lower than the fusibility of half and half solder.

Attention is also called to the fact that the compressive strength of Nos. 10 and 11, which contain neither tin nor copper, is equal to that of No. 3 at 1,000 lbs. pressure per square inch, but at the higher pressure the No. 3 shows greater sustaining strength, due doubtless to its greater malleability, but such high pressures are rarely, if ever, used in actual practice. It is rather anomalous that alloys Nos. 1 and 2, which contain less copper and antimony than No. 3, should show greater resistance to pressure.

The conclusion that can be drawn from the foregoing figures is very favorable to the use of lead base alloys for all bearing purposes except in cases where malleability is a prime requisite and paramount to all other considerations on certain forms of thin, loose shell bearings.

The lead base metal is unquestionably superior anti-frictionally to the tin base metals and by reason of that quality it wears longer, runs cooler and protects the bearing from the injurious effect of frictional heat, and it is very much cheaper.

The lead base metal also has an advantage in pouring as the tin base metal with high copper content has to be brought to a much higher heat to obtain the proper fluidity to obtain a good casting.

These figures of tests are doubtless dependable, and assuming that they are at least approximately correct, they unquestionably show the fallacy of using the copper-hardened tin base metals merely to obtain compressive strength and apparently authorities in these matters have been taking a good many things for granted.

The fact that lead base metals are being used successfully under extremely high pressures is evidence that their failure in some instances where the tin base metals succeed is doubtless oftentimes due to improper handling rather than fault of the metal.

THE DEVELOPMENT OF NITROGEN FIXATION IN AMERICA

In a lecture on the nitrogen problem, by Professor A. A. Noyes, at Washington recently, the author said that as regards "fixation" processes, America is now working, to a greater or less extent, all the methods which have been developed during the past fifteen years. Even before the war the American Cyanamide Company at Niagara Falls was producing about 20,000 tons of cyanamide a year, largely for use in agriculture. By the action of steam upon this substance it is practicable to get substantially all the original nitrogen in the form of ammonia. This process is capable of a great extension, and has already reached considerable proportions in Germany, where it competes with the Haber process. The American government is building a cyanamide plane with a capacity of 110,000 tons of ammonium nitrate at Muscle Shoals, Alabama, and a third plant has been authorized for the production of another 110,000 tons in Ohio. The cyanamide process has the advantage that it can be installed in many places in the country, and that it requires little power. It has probably a great future before it—certainly immediately—but whether it is ultimately destined to be supplanted by the synthetic process time alone can show.

WELDING AND CUTTING

IMPROVED LEVIN OXY-HYDROGEN GENERATOR

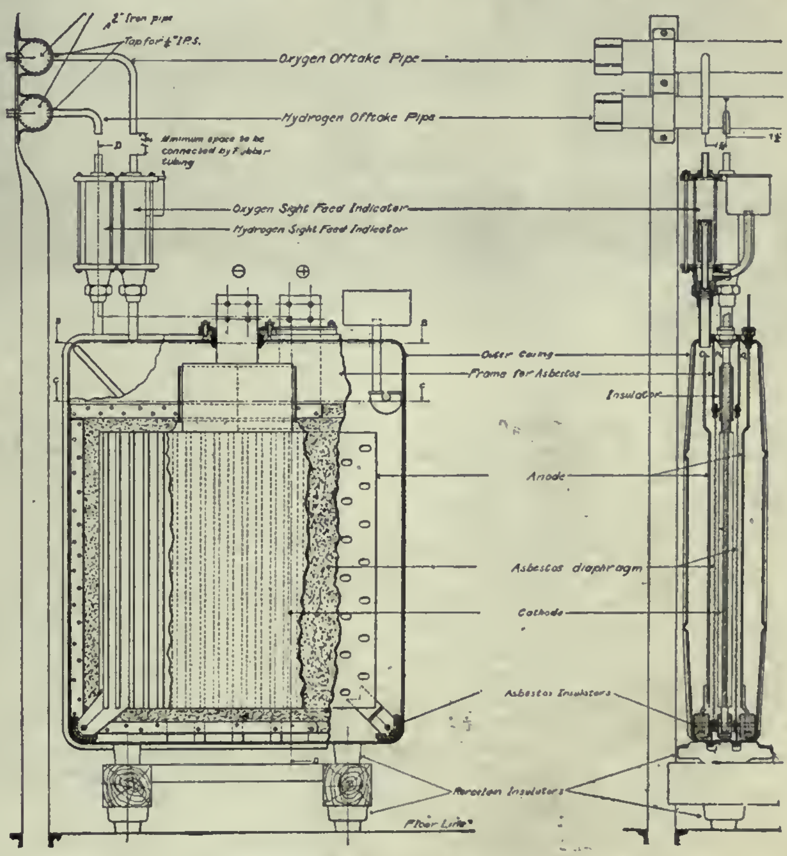
THE demand for oxygen in connection with the oxyacetylene process having increased in enormous proportions, several firms have contemplated installing their own oxygen plants in order to decrease their outlay for gas and at the same time assure themselves of a constant supply, thus avoiding delays due to effective transportation and the cost of the same. In view of these conditions the following may be of interest. The accompanying half-tone and line cut illustrates the Levin type of generator for the decomposition of water by means of electrochemical action, for the production of oxygen and hydrogen for commercial and chemical purposes. These generators are designed on the unit principle, being small and compact, simple in construction, and

EXTERIOR VIEW OF CELL

built of a few standardized parts which insures rapid and accurate assembly. Each generator consists of three compartments, the oxygen being generated in the two outer chambers and the hydrogen in the inner or centre compartment. The division walls are comprised of two sheet metal frames supporting asbestos diaphragms. The electrodes are independent of the casing, being separated from it, but fixed in position by means of the specially designed blocks of asbestos, for efficient insulation. A distinct feature of the generator is the use of Cobalt on the electrodes. Water is fed to each compartment independently, the inlets also providing a suitable blowoff or vent from each section, when the generator is operating under abnormal conditions.

A specially designed sight-feed indicator is located in the discharge pipe, between the generator and the main offtake pipe. This method makes each unit independent of all others in the group. The individual indicators not only serve to maintain uniform pressure in the different compartments of each unit, but enable the operator to see at a glance the action of the generating process and the quantity of the gas being formed. Another important feature of the generators is the total absence of packed joints, a very essential factor in the maintenance in this class of equipment. Each unit is completely assembled at the plant of "Electrolabs," and the casing entirely sealed by means of welding. This is made practically by eliminating all material or component parts that would have a tendency to deteriorate through the action of the electrolyte, the formation of the gases, or the electrochemical action of the decomposing process. No elaborate installation work is required, as each unit is ready for operation immediately it is delivered, the only necessary detail being the placing of the short rubber connection to the main pipe lines and the filling with electrolyte.

The general dimensions of these generators are 30 inches in height, 25 inches in depth, and a width of about 6¼ inches. With the floor supports and porcelain insulators in position and also the upper pipe connections, the total height is not more than 4 feet 8 inches, thus insuring easy access and view to every portion. The unit system provides for the installation of sufficient equipment to meet the specific needs of the user, and the generators can be so arranged as to occupy the minimum amount of floor space, the replacement of a unit not requiring any more space than that occu-



ARRANGEMENT OF APPARATUS

pied by itself. The approximate production of one of these units, operating at 200 amperes, for 24 hours, will be 38.4 cu. ft. of oxygen and 76.8 cu. ft. of hydrogen, measured at 20 degrees C. and 760 m.m. pressure.

C. Royer, formerly general manager of the L'Air Liquide Society and acting manager of the Welding and Supplies Co., 1227 Ontario St., Montreal, is the Canadian representative of Electrolabs.

NEW WELDING PLANTS

The St. Lawrence Welding Co., Ltd., Montreal, have opened a new branch in Halifax, N.S., at the end of Evans Ltd., plant on the Dartmouth side. They are equipped to handle all classes of welding, oxy-acetylene, thermit and electric processes. This branch was opened about the middle of May and is now doing a large business in the welding line.

WELDING TUG OF THE ST. LAWRENCE WELDING CO.

The plant is equipped to take care of ship work and lead burning, and the firm is now fitting out a tug in the harbor that will be equipped with electric welding apparatus and an oxy-acetylene unit, also an air compressor of large capacity for operating the tools for necessary repair work. The tug will also have a large fire pump for fire fighting purposes. The branch will be managed by Mr. A. Young, an old employee of the St. Lawrence Co., who will work under the supervision of A. M. Barry, the managing-director. This company has branches in several of the large Canadian centres and anticipate the opening of additional ones as soon as the necessary organization can be trained.

Toronto.—We regret to announce the death from Spanish influenza of Capt. Anthony Randle. Capt. Randle came here in May last from England to take command of the ss. Asp, building at the Polson Iron Works. The deceased was only 31 years of age. His body will be shipped to England.

BOILER AND OTHER REPAIRS BY ELECTRIC WELDING*

WELDING is one of the oldest branches of the working of metals. In some respects it is a lost art, as there are good grounds to believe that the ancients were able to weld some of the bronze alloys. In the following remarks the author proposes to confine himself to the welding of iron and steel, unless otherwise stated. A weld is the intimate union of two pieces of metal, produced when the pieces have been raised to welding heat, by pressure or hammering, and the welding state of a metal only exists within a limited range of temperature, being something like 100° for iron and steel, but varies with the metal. As a rule, good iron will stand a higher temperature than steel, although certain steel, such as blistered or good shear will stand a high temperature. In the smith's fire steel can, and should be forged with a lighter tool than iron, the blows being in rapid succession. In the ideal weld the two surfaces to be united are brought to the plastic heat together, neither at too high or too low a temperature, when the point of juncture should be as strong relative to its section as any other portion. From the foregoing remarks, however, it will be appreciated that much depends upon the skill and experience of the operator, and it is recognised in ordinary engineering practice that an allowance has to be made for inevitable human frailties.

The first process of electric arc welding to be employed in a commercial sense was that of De Bernardos, which was used in Messrs. Lloyd and Lloyd's Works, over twenty years ago, in the welding of flanges and branches to iron and steel pipes. In the De Bernardos process a carbon is employed, an arc being drawn between the carbon and the job, a portion of which is brought to welding heat, and the added metal is heated in the flame of the arc. In the early Bernardos process the work was made the negative pole and the carbon the positive, but latterly the poles were reversed, thus doing away with the dangers of carbonisation of the metal caused by the natural flow of carbon particles from the positive of the negative. The Bernardos process is still largely employed in this country. Slavianoff substituted a metal electrode for the carbon electrode of the Bernados process, although Bernardos as far back as 1885 had the idea of using a hollow carbon filled with the adding metal. In the carbon electrode of the Bernardos does not seem to have anticipated, his difficulty being that, like many other great inventors, he was in advance of the means and appliances of his time. The names of many investigators and workers in our own and other countries during the eighties and nineties of last century could be honorably mentioned, each doing their little bit to advance what is practically a new trade. Among them Charles Lewis Coffin, of Detroit, U.S.A.; Mark Wesley Dewey, of New York, U.S.A.; Pommée, of Altona, near Hamburg; W. P. Thompson, of Liverpool; Thos. Odlum, of Virginia, U.S.A.; Francis Todd, of Newcastle-on-Tyne, and Joseph Fouilloud, of Paris.

We have already referred in the Bernardos process to the arrangement of the poles of the electric arc. Now it is generally agreed that the province of the engineer is to utilise the forces and methods of Nature for the benefit of mankind, and Nature in this case has provided that the positive pole of the electric arc shall be much better than the negative pole. We consequently arrange in electric arc welding that the positive pole shall be on the bigger mass, which in 999 cases out of 1,000 is the job, and the negative pole on the smaller mass of metal, which in modern electric arc welding is the metallic pencil of the adding material. By working with Nature we thus provide favorable conditions for the first essential of a good weld, namely, that the pieces to be united shall be brought to a welding heat at the same time. You will note that we have only provided favorable conditions; the actual carrying out of this requirement rests with the skill of the operator. This consideration of the difference in temperature of the two poles of the electric arc makes it at once apparent why direct current is more suitable than alternating for arc welding. On the other hand, alternating current is quite suitable, and probably better than direct current for what is known as resistance welding or for spot welding.

*Read before the members of the Institute of Marine Engineers, on March 12th, by Mr. R. S. Kennedy, Member of Council, I.M.E., M.I.C.E., Member N.E.G. Inst. of E. and S.

The author's Company* were the first to employ the metallic electrode in this country on a commercial scale—namely, early in 1910, although about a year previously Mr. Copeman, of the Furness Lines, had carried out a few experimetal jobs to his own vessels. Since 1910 the annual output of the British Arc Welding Company has increased at least 100 times, and during the present war its services have been utilised in directions which would not have been permitted under peace conditions. In making this statement, however, the author wishes to acknowledge assistance received from kindly and constructive criticism from the Board of Trade and Lloyd's Register in pre-war days,but everything has now been speeded up. In particular, the tests of electric-welded specimens carried out to the instructions of the Board of Trade in 1909 and 1910 were of great value.

These tests were made not only with the object of getting at the tensile strength of the weld, but of finding out if the process of welding affected the neighboring material. Numbers of specimens were tested, and some of these were annealed, but it was found that annealing made no difference to the results, and the material immediately adjacent to the weld behaved in a normal manner. These tests gave a tensile strength of about 17 to 18 tons per square inch, but since then improvements in the materials and methods have increased the tensile strength of weld in boiler steel to about 27 tons per square inch. In practice, however, the author would not recommend that a tensile strength of more than 20 tons per square inch be worked to, this giving a sufficient margin for possible small defects in workmanship. It might here be remarked that in no single case has the author known an electric weld to give way suddenly; failure has always been preceded by a small crack, which has gradually developed.

Electric arc welding is primarily a form of autogenous welding—that is to say, the metals to be united are heated to such a temperature that they will fuse together on contact without the application of external pressure. It is, however, found in practice that the application of even the moderate amount of pressure produced by a hand hammer increases the tensile strength and tenacity of the weld some 5 per cent. It is, however, essential that this work should be put into the material when it is at welding heat or, at any rate, above the black heat. It may here be remarked that it is often said that the value of metal added in this fashion is analogous to the ball of iron obtained in the puddling furnace. This, however, is not the case, and the better results are probably due to the fact that the iron wire used is of the very best material, with preferably a small percentage of manganese. This iron wire has been very heavily worked in the process of

*The British Arc Welding Co., Ltd.

FIG. 1—(TOP) BEFORE WELDING. FIG. 2—(BOTTOM) AFTER WELDING.

manufacture, and subsequently annealed, and as used by the author's firm shows a tensile strength of 28 tons with an elongation of 50 per cent. Somewhat similar results are obtained in another field with cast iron, which has several times been re-melted. The whole question of the amount of work put into the material of a weld is very fascinating, and there is no doubt that the capacity of a weld for taking up rapidly alternating strains for a long period, and for absorbing sudden shocks, very much depends upon this factor.

Returning to our blacksmith, whether under the spreading chestnut tree or in in the more prosaic conditions of the modern smithy, we find that they all employ some kind of flux, usually sand or borax. This flux surrounds the heated iron or steel and protects it against the impurities of the fuel, removing at the same time the coating of scales. Some impure wrought irons flux themselves, but with steel other mixtures are used. The flux, as its name indicates, also increases the fluidity of the heated metal.

In electric arc welding with a metallic electrode one great advantage is that, with the exception of the atmosphere, we have no impurities to guard except such as are introduced in the materials. The source of heat is pure, and we have to see that the job is properly cleaned and the metallic electrode of suitable material. Still, to provide against oxidisation and also to increase the fluidity of the metal a flux is necessary to good work in arc welding, and the heated metal is protected from oxidisation by an inert gas given off by the flux. The most convenient method of applying the flux is to coat evenly the metallic electrode, thus providing a constant and uniform supply.

Electric arc welding is a process of building up, and consists of adding metal to an existing structure. For this type of welding the electric arc has one great advantage in its high temperature. This is the highest known, and thus by the application of a small number of calories a part of the job, say, about ½ in. diameter, is almost instantaneously raised to welding heat, and the drop of adding metal from the pencil, also at welding heat is united to it, and the process of building up is continued till the required section is reached. The small quantity of heat required does not cause any undue expansion of the job in hand, and contraction troubles are reduced to a minimum. It is quite a common practice to weld over a riveted seam, although in this case it is necessary that rivets in the area dealt with should be completely welded over, and not left half covered. After welding a seam it is necessary to caulk the landing edge for some 6 ins. at each end of welded portion. Cracks in furnaces, end plates, combustion chambers, etc., are dealt with by cutting out the defective portion, leaving a V-shaped opening, which is filled in with the welding material. Work can be carried out directly overhead, or in any position that is accessible to the welding pencil, and where the operator can see what he is doing. As the work is one requiring constant attention on the part of the operator, it is advisable, in order to get the best job, to make it as accessible as possible, and that the operator should be reasonably comfortable.

In common with all hand welding, a good job depends on the conscientious work of the man. The author's firm have always trained their own welders, and keep them in constant employment. A full report is made of each job, and the name of the welder recorded, and the whole object of the training is to inculcate a sense of responsibility.

The materials at present dealt with on a commercial scale are wrought iron and steel and cast steel, and occasionally cast iron. The range of temperature of the welding heat is the determining factor in the adaptability of a substance for welding. Much successful work has been done with cast iron, notably with castings of considerable age, which have not been subjected to corrosive action, and with the good mixtures of more modern times. It is probable that there is a welding temperature of cast iron, but the range of this temperature is very small, something of the nature of 10°.

The voltage across the metallic arc is about 22 to 25, and the writer adds an equal steadying resistance which makes the voltage at the terminals of the dynamo about 45. A substantial resistance is employed which is put in circuit by an automatic switch, when the welder breaks his arc, thus keeping the load on the machine constant. The amperes actually employed are about 175, but in practice a 200-ampere machine is necessary, while the author's firm use machines designed for 250 amperes. In the big passenger liners it is the practice to weld from the ship's dynamo, suitable welding and substitutional resistance being provided. By a special winding of the dynamo, known as separate excitation, the machine can be steadied under varying loads, but even in this case the author still prefers to retain the substitutional resistances in addition.

The design of the portable machinery for generating electricity presents many interesting problems. Plant is designed to meet the varying conditions, and consists of wagons generating their own electricity, portable petrol driven generating sets, self-propelled or dumb barges with steam-driven or paraffin sets, steam turbine plants, and last, but not least, the motor generator sets

The preparation of a job for electric welding is a matter of considerable importance, as the presence of impurities is likely to be detrimental to the weld. In dealing with the external or fire surfaces of a boiler it is usually sufficient to use an ordinary chipping hammer, and then thoroughly wire-brush the metal to be dealt with; but some superintending engineers prefer to have a light chipping taken over the surface, which is, of course, the ideal preparation. In marine work, however, the time available is often so short that as a general rule the former method is adopted. When, however, it comes to dealing with the water surfaces of a boiler greater care is necessary, especially if zinc plates have been freely used. The welder, if a properly-trained man, would at once recognize this difficulty and apply the only remedy, which is to chip down till pure metal is reached.

Arc welding being a building up process, cracks are dealt with by veeing out at the line of fracture, the vee being made wide enough to ensure that the welder can reach with his pencil to the bottom on either side with a certainty of striking his arc at any required position. As the welder is a highly skilled man, it is usual for the boilermakers to prepare the work to instructions, and the welder himself puts in the finishing touches. The welding in of new backs to combustion chambers or tube plates, or work of that kind is dealt with in precisely similar manner, although here certain allowances have to be made for the work drawing together as the welder proceeds. It should be mentioned that in dealing with cracks it is absolutely essential that the whole of the fractured portion be cut away till a solid chipping is obtained, and then go a bit deeper to be on the safe side. If welding is carried out over a partially cut away fracture it is certain that sooner or later it will work to the surface. One of the most unsatisfactory matters we have to deal with is the welding of a crack in the original weld of a furnace, as it is most difficult to say where the defective weld ends, and a further defective portion some short distance along may work back into the part dealt with.

As in all engineering matters, it is better to know the worst and deal with it. The writer recalls an incident in our early days—about 1910—when we were called in to weld a crack, apparently about one inch long, in the back of a combustion chamber of a Swedish vessel. Our man started to cut out the crack when with a loud report the chamber back split right across, showing a fracture a full sixteenth open. This caused great alarm at first, and we were charged with using undue vigor, but on veeing out the fracture for welding it was found that the back was grooved right across on the water side, so we were exonerated. It is a merciful dispensation of Providence that such defects develop mainly when the boiler is cold or under banked fires, and it is generally recognized that a boiler is never safer than when warmed up and steaming steadily. Owing to its higher temperature the electric arc is more suitable for dealing with the heavier sections than the oxy-acetylene or oxy-coal gas, while, on the other hand, for thickness of 3-16 in. and under one or other of the gas systems is preferable.

The author has been asked to summarise as briefly as possible the conclusions reached in the very able papers recently read by Commander E. P. Jessop and Naval Constructor H. G. Knox, both of the U. S. navy. The principal welding consisted of the repairing of the cylinders of some eighteen German vessels, where large pieces had been broken from the upper portions. The method of repair consisted of the welding in by the electric arc or oxy-acetylene gas of a new piece in cast steel or cast iron to replace the portion broken away. In arc welding the old and useful device of tapping short steel studs into the cast iron was used to enable the added steel (in this case) to make a surer weld. The electric arc welding repairs were carried out with the cylinders in place, while with the oxy-acetylene process it was necessary to remove the cylinders so that the joints for welding could be laid in a horizontal position, and also that the cylinders could be heated. Commander Jessop quite truly points out that the great difficulty found in the arc welding of the cast iron surface was to get the first layer of the adding steel material to adhere, and that this layer was always added before the patch was put in position for welding. In the oxy-acetylene jobs, as before remarked, the cylinders were secured in place, and, the joints being horizontal, both sides of the joint were made fluid, and cast iron sticks melted into the bath thus formed. Both methods appear to have given excellent results, and the repairs are certainly the largest of their nature that have yet been carried out, and reflect the greatest credit on all concerned. It would not be wise, however, to generalise on the treatment of cast iron from these results. You will remember that we have before remarked that with good mixtures of cast iron one can with fair certainty make a good weld. It must be remembered that these were high class vessels, and that in all probability the very best metal would be used in their cylinders and liners, and certainly in superheater jobs the H.P. cylinders and liners would be of a very special mixture, which so far as the author's knowledge is concerned has only been made in this country during the last five or six years. He trusts that we may hear further on this point, but his present information is that these vessels were superheater jobs.

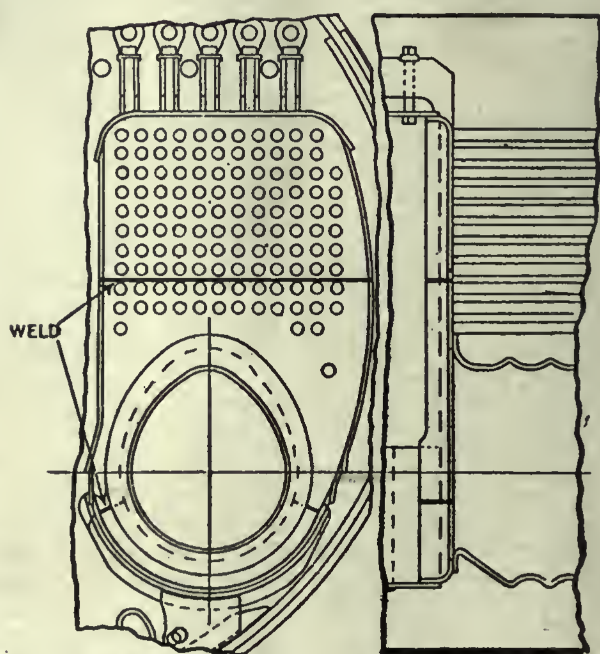


FIG. 3—NEW LOWER HALF TUBE PLATE WELDED IN.

The author claims that arc welding, where carried out by skilled operators with suitable materials, is absolutely re-

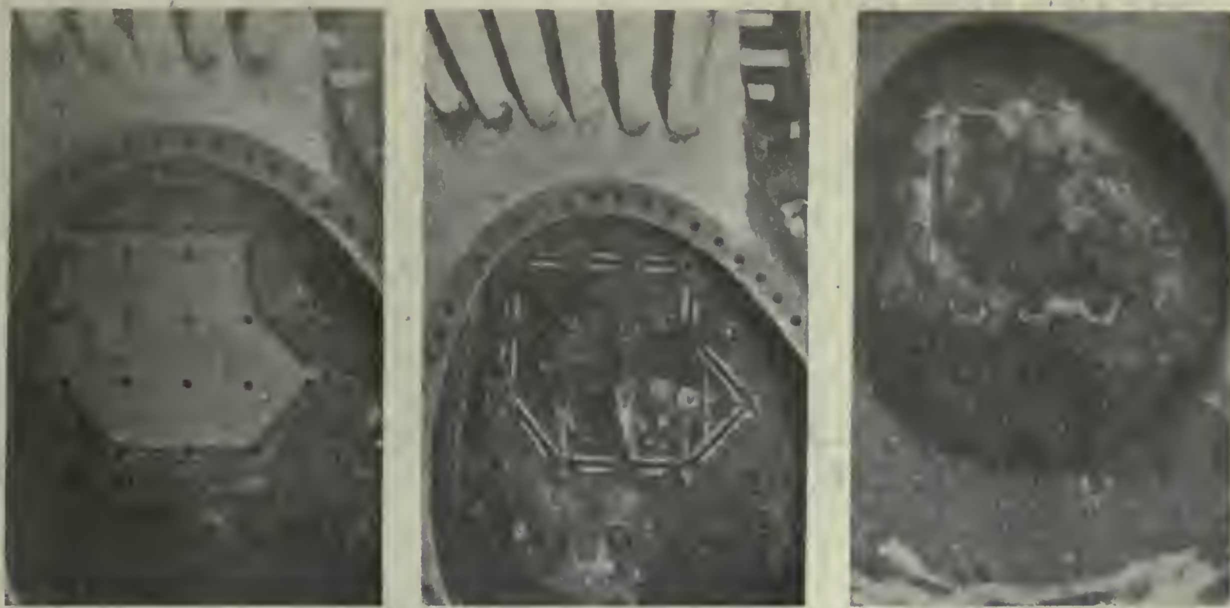

FIG. 4—MARINE BOILER COMBUSTION CHAMBER BACK

liable, and can point to some 20,000 jobs, some of a very big nature, while the percentage of even partial failures would, at any rate, be on the right side of the decimal point. These partial failures would be mainly accounted for where the work was carried out under unfavorable conditions, and often in the nature of a forlorn hope. Great difficulties are met with in hurried repairs to the lower portions of the hulls of vessels in dry dock, where water is constantly dripping from the leaky portion, and owing to the cement inside it is often impossible to stop it in the time available. It must, however, be remembered that metal added by the heat of the electric arc or other method's has not been subjected to the same amount of work as a rolled steel plate or forging. It is, therefore, not so well adapted to take up work suddenly applied, and one would not recommend it for a position of responsibility where such conditions arise. This, however, is a condition generally recognised by engineers with all welds.

The question of the resistance of welds to rapidly alternating stresses and shocks is somewhat obscure. Some year or two ago the author's firm were asked to weld the broken piston rod of a 10 cwt. steam hammer which had already been twice welded in the fire. This was carried out, and is now running satisfactorily. It is not permitted at the present time to refer specially to work carried out, but outside of the boiler repairs, repairs to hulls include the welding of broken stern frames, "A" frames for twin screws and the welding in of a new piece of stem is quite an everyday occurrence.

Boiler repairs are of infinite variety, and include the welding up of cracks to any extent, the welding in of new plates, thickening up of corroded surfaces, and building up of landing edges and defective rivets. Leaky stays and tubes have been welded in position with excellent results, and in cases of trouble with stays with loose washers it is excellent practice to build up from the solid plate to form the washer, which can then be faced off with a special tool.

The superintendent engineer of Geo. Thompson & Co. had carried out the first electric welding repair of any size, being the welding up of a number of cracks in the Purves furnaces of the ss Moravian. This was closely followed up with large repairs to the circumferential seams of the boilers of the Port of London authority's hoppers Nos. 3 and 4. One of our vice-presidents was early in the field, and it was due to his insistence that resistance plant was designed to weld from the ordinary electric-lighting sets of the larger vessels. Generally, however, it was found that the process supplied a long-felt want, and the author's task consisted mainly in seeing that none but fully-trained welders were allowed to undertake any welding repairs. The author's father, Mr. John Kennedy, and his Hamburg colleague, Mr. Bartlett, were the prime movers in introducing the process of the metallic electrode to this country, and the former was a tower of strength when in the early days it was necessary to overdraw at the bank, while Mr. Halket and Mr. Thom were indefatigable in assisting and advising in early experiments.

As referred to above, a number of slides were shown by Mr. Kennedy, illustrating in a general way the type of work carried out and a few of the repairs are shown in the accompanying illustrations.

One of the slides was of the first motor wagon plant used for electric arc welding. The chassis was originally built by J. and E. Hall, of Dartford, to W. A. Steven's patents as a petrol electric motor-'bus, and was the forerunner of the present Tilling-Stevens petrol electric motor-'buses. This machine ran experimentally between Roehampton and Brighton, but was bought by the author's company and the electrical equipment converted to arc welding purposes, still retaining the electric road drive. The same principle was adopted by the War Office for portable searchlights. The chassis is driven by two motors, which engage the driving wheels through a worm drive: in the later machines the driving is from one electric motor, which drives a cardan shaft, and ordinary differential gear to the driving wheels. When the machine arrives at the job the current is switched from the road drive to the welding circuit, so that the same engine and dynamo answer both purposes.

Figs. 1 and 2 show repairs carried out in January, 1912, to one of the Canadian Pacific liners in Liverpool. Fig. 1 shows the defective portion of the flanging of the front end plate cut out ready for welding, and Fig. 2 the completed repairs.

Fig. 3 shows a repair carried out in May, 1912, to one of the Atlantic transport liners at Tilbury. Two tube plates were thus dealt with, and in a number of other furnaces smaller portions were cut out and new pieces welded in. This repair was the most difficult that had been up to this time attempted, as it was necessary to weld the new lower half to the existing half tube plate perforated with holes for the tubes. It was, however, satisfactorily carried out, and has never given any trouble. It may be of interest to mention that nine tube plates have just been similarly dealt with at Cardiff for the same owners.

Fig. 4 shows a repair carried out in November, 1911, to the back plate of the combustion chamber of a marine boiler. The first view shows the defective portion of the back plate cut away, the second, the new portion of plate in position for welding, and the third, the completed job. It will be noted that the plate has been cut through the line of stays, being the method recommended by the surveyors, which is undoubtedly preferable.

Work as if you owned the place—and perhaps you may.—Elbert Hubbard.

TEMPORARY REPAIR OF A BROKEN STOP VALVE

By T. H. F.

An interesting repair of a bad break came under my observation when sailing as 3rd engineer of "S.S.———." We were bound from Cardiff to Nagasaki, Japan, though as we were carrying Welsh coal for the Japanese navy, and Japan then being at war with Russia, our ostensible destination was Shanghai for orders. However, we had come down the Red Sea with its usual discomforts, across the Indian Ocean, and were making up for Colombo to coal. We sighted the harbour about 7 a.m., and about 7.30 the first officer gave orders to the bo'sun to get steam on the windlass, preparatory to anchoring. Now the bo-sun had sailed in steamers so long that he was, in his own mind, something of an engineer. Therefore, instead of notifying the engineer on watch that steam was wanted on deck, he undertook to put steam on himself. The two valves controlling steam to the fore and aft deck were situated in the fidley, at the bridge deck, and easy of access to anyone. The gallant bo'sun, whose engineering knowledge really was all comprised in the ability to turn a wheel to the right or left, which would open or shut a valve, naturally never thought of the fact that the steam had not been on the deck pipes since leaving Suez, so he stepped into the fidley, took the wheel in his tarry hands, gave it a mighty twist, and then things happened. It was here that the chain of events reached me personally. The messroom steward had just entered my room to call me, and I was sitting on the edge of my bunk, rubbing the sleep from my eyes, when a terrific report, followed by the roar of escaping steam burst on my ears. I jumped from the bunk into my engine-room slippers, and in pyjamas and slippers, made for the engine-room. After the first shock my ear could still distinguish the beat of the engines, and there was no sign of steam in the engine-room. Going on the top grating I opened the door leading to the boiler tops, but though the noise was plainer here, there was no steam. As I turned back again, the second came up from below, and made toward the door, beckoning me to follow. He went to the auxiliary stop valve on the port boiler and motioned me to the starboard boiler. These were shut off, and quietness reigned once more. This sounds simple, but any of my readers who have gone on boiler tops in tropical weather clad in pyjamas and slippers will appreciate the pleasure of it. As we came out onto the top grating again, I asked the second what was damaged, and elicited at first a very complete and highly ornamental biography of our bo'sun, bo'suns in general, deck officers and skippers, winding up with the announcement that the donkey boiler stop valve had been blown off. This was the case.

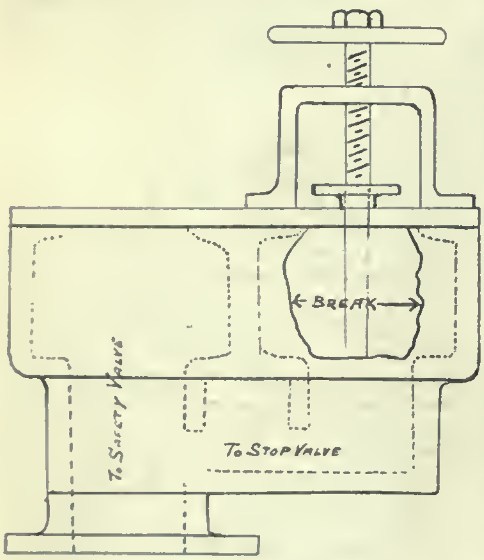

FIG. I—SHOWING BREAK IN STOP VALVE WALL.

Steam for the winches and windlass was taken from the main boilers, through a reducing valve, and from the donkey boiler. The pipe from the reducing valve joined the donkey boiler pipe close to the valves controlling the deck steam. The donkey boiler was situated on the main deck, and from the donkey boiler stop valve to the bridge deck where controlling valves were situated, was about 30 feet in length, with a rise of about 3 feet. Now it was the practice to leave steam when at sea, open on the main boilers to the reducing valve, and up to the fidley, so that if steam was needed on deck, it could be opened without anyone having to go on the boiler tops. As no one but an engineer was supposed to touch the valves on deck, there was no danger. When the bo'sun threw open the valve a slug of water started off, and the first obstacle it struck was the donkey boiler stop valve, which surrendered. The stop valve was contained in the same casting as the safety valve, which made it more awkward. The first thing to be done was to blank the pipe off between the donkey boiler and the supply from the reducing valve, so that steam could be put on deck to handle the anchor in Colombo. This little job being done, a hurried visit to the messroom was paid, where the dried up remains of breakfast were bolted just as the stand-by rang for the pilot. This was the beginning of a perfect day, the remainder being spent between tallying coal and doing little jobs in the engine-room, such as packing the H.P. gland, etc., with the sweat forming pools wherever one stood. The delights of a coaling port ending like anything else, we were under way again about 8 p.m. with the next stop Singapore.

Next morning after breakfast, the chief, second and myself went forth to inspect the damage, and see what could be done. It was essential to have the donkey boiler at work in port, so that the main boilers could be cleaned. The side of the stop valve wall had been blown clean out as shewn by the sketch, but the lower port and safety valves were intact. The cover was good, and the valve itself not damaged. The first thing suggesting itself was to make a patch out of some plate we had, ¾-inch thick, but upon going further into the matter found this would be a job of some considerable magnitude, and other means were looked for. It was finally decided not to attempt a patch, but to use a temporary expedient that would serve till we arrived at a home port, where we could get a new casting. Looking through the stores we found a copper bend 90°, with flanges each end. This was the right size, 4 inches, if I

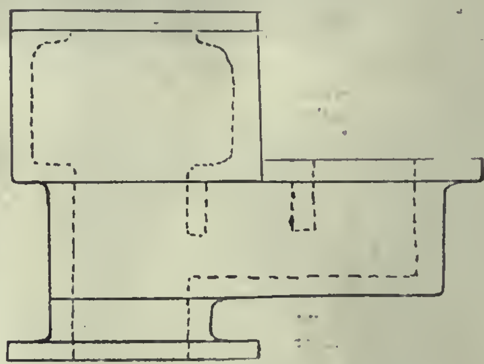

FIG. 2—SHOWS STOP VALVE BOX WELL CUT AWAY TO RECEIVE FLANGE.

remember rightly. The whole casting was taken from the donkey boiler top and lowered down the fidley, and taken to the engine-room vice bench. The broken wall of the stop valve was drilled all round and cut off with a chisel, leaving a flat face. The seat of the stop valve was drawn out, and holes drilled for studs to fit the copper flange. Of course, this took time, as it had to be done by the engineers in the course of their watch off. However, it was finally completed, and the casting replaced. The bend being bolted on to the casting its vertical flange came in approximately the same position as the stop valve flange had been, and the pipe was connected up with a blank flange in between. The method of working was as follows; On arriving in port the steam for the winches would be used from the main boilers during the remainder of the day of arrival. When cargo working for the day was finished, steam was shut off from the main boilers, the blank flange was removed and the donkey boiler lit up, steam being ready for the morning. When getting ready for leaving the modus operandi was reversed. The main boilers would be, of course, lit up and steaming and when cargo was finished the donkey boiler was blown down, the blank flange put in again, and steam opened up from the main boilers. By this means there were no delays, and the time of putting in and removing the blank was about 10 minutes. As we called and worked cargo at Moji, Hong Kong, Moulmein, Fiume, Aggiamarina, Tripoli, Tunis, Tarbis, Holmis, before we arrived at Antwerp, some months later, where our casting was awaiting us, we got quite used to the blank flange drill, and somewhat missed it after the new casting was placed.

GETTING HIGHER SPEEDS AND FEEDS

By D. A. HAMPSON

Any executive will tell you of the persistence of men—other than piece workers—in using speeds and feeds that are too low. There does not seem to be any feeling on the part of machinists to delay the work, yet they do not use their thoughts in an effort to "speed it up," even though it would entail no more exertion on their part. In one plant employing a thousand men the foremen made it a practice to push off a belt when it was on too slow a step of a pulley—this after the men had been instructed carefully and failed to heed; the man at a machine who found his feed belt lying on the floor as the foreman passed was pretty apt to come out of his dream to a realization that the foreman meant business. And by just what reasoning men use a measly fine feed when an additional cut is going to destroy all this lovely finish is hard for an observer to comprehend.

One plant attacked the problem in a different way. Friendly instruction had failed to produce all that it should and it was not the policy of the management to nag the men. Three of the shapers were of the type where a spring pin can be dropped in a series of holes to give feeds from 0 to five teeth on the ratchet. The men persisted in dropping the pin in the one-tooth holes. These were all plugged up—the men grinned and went on with their work. turning out double the amount of chips in the same time; later the work was rearranged so that the rougher class all went to one machine and another hole in it was plugged, leaving a three-tooth feed as the minimum. Soon the men forgot all about finer feeds and turned out just as nicely finished work.

Jobs set up for runs of a day or more were belted up by the foremen with absolute instructions to leave unchanged. Many of these jobs ran for months and at first the men laid all the trouble and inaccuracies to the "speeding up," but as time passed this, too, was forgotten and the men used their common sense in locating trouble. One job on a battery of millers had always been set by a man of experience in that line. Someone else discovered that the cutters could run fifty per cent. faster before they exceeded the book speed for that steel and, though loudly protested by the man of "experience," the results proved the correctness of the change.

On the lathes a similar change was made. Where there was a two-speed shift gear, it was locked or pinned in the fast position. Set jobs were speeded up by changing the feed gear ratio—sometimes this was done at night and the workman never knew the difference. It is enlightening, having tried the thing, how much faster feeds and speeds can be used without trouble when there are none slower available.

GRINDING LEATHER

By D. A. H.

In experimental work and in the course of miscellaneous repair work, it sometimes becomes necessary to machine leather, maybe a friction wheel, or a leather coupling, or a polishing wheel faced with leather. When the leather is stiff, as discs of sole leather between flanges nearly the same size, it can be turned readily and smoothed off with sand paper. But it is not the purpose here to dwell on turning and drilling in the usual manner.

In developing a moving picture machine particularly adapted to the special scenes that the war has given us, a number of rollers were required about two inches in diameter, an inch face, 5-16 in. hole, and with a leather facing less than an eighth in thickness. The periphery of these rollers had to be concentric within .0005 in., smooth and firm. Turning was out of the question—the fuzz and general ragged cut left by a tool demanded a dressing down with sand paper and this destroyed the accuracy, if any. So, merely as a guess, grinding was tried. The first roller was ground in the tool room and was a complete success. A hard, straight surface resulted as if by magic. The same wheel was used that was used for cutter grinding. Later, tool post grinders in the lathe were tried and with an equally pleasing result. No finishing was needed for the emery wheels left a surface as smooth as metal, which needed no touching up and raised no grain, consequently any cut might be a finishing cut and could be micrometered at once.

A CELEBRATION WITH NO BOOZE

The Editor CANADIAN MACHINERY.

Sir:—In my five years' acquaintance with CANADIAN MACHINERY it has not hitherto been my experience to read any editorial which displayed the bad taste and ignorance of yours under the above heading on Nov. 14.

Bad taste because of the reference to England as "weakened by booze" and "in the face of national disaster unable to rise in its might and strangle the slimy thing." This weakened nation, you will remember, raised one soldier out of every six of her population, whilst Canada, with the help of the Temperance Act, finally raised one in sixteen. England has paid a price for victory which we in Canada can never conceive. The smallest tribute we can pay is to refrain from such criticism as the above.

You may be aware that on at least two occasions an attempt was made to force prohibition in England, but was defeated by the common people of the country refusing to work under this restriction of their liberties.

The two battles of the Marne were won, Verdun was saved and the barbarians were finally ejected by the Poilus of France, whose fighting qualities were certainly not diminished by their daily ration of a pint of wine per man.

I can hardly endorse the claim that only those whose strongest drink is tea can be "sober and decent," their language, as shown in your article, is neither the one nor the other, and I enclose my name for the benefit of the writer of your article, with whom I would be glad to debate the matter at any time or place. In conclusion, I would like to refer you to a letter which recently appeared in "Saturday Night," signed by a prominent local manufacturer, affirming that the best class of labor was leaving the Dominion where the liberty of the individual to choose his own form of drink was suppressed and that a repeal of this oppressive legislation was in the best interests of industry.

Yours etc.,

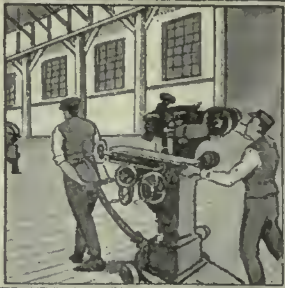
VERITAS.

"The Heating of Houses, Coal and Electricity Compared" is the title of Bulletin No. 6 issued by the Honorary Advisory Council for Scientific and Industrial Research, Ottawa. This publication summarizes the advantages and disadvantages of both the methods of heating, and reduces their cost to an equal basis for a comparative purpose during the past few years and the fuel problem has become acute in Canada, and an idea appears to have been gaining ground that the immense water powers of this great country will amply suffice to meet all heating requirements. The climate of the greater part of Canada is so severe in the winter that even the immense potentialities of its water powers, if fully developed, would be altogether inadequate to cope with the demand for power for electric heating if this were increased to any great extent.

The advantages of electric heating and the difficulties preventing the adoption of electric heating on a large scale are dealt with, and the cost of heating a house electrically at a lowest domestic lighting rate is also given. This cost will be considerably lessened by the use of electricity supplied at power rates, but in this case even, it will not be possible to bring it within the cost of heating by coal.

Factory Finished.—The new plant of the Huntley Co., Tillsonburg, is nearly completed and will be opened shortly. A patriotic dance will be held in it on the 22nd, the proceeds of which will go to Red Cross purposes.

DEVELOPMENTS IN SHOP EQUIPMENT



Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.

UNIVERSAL CONVERTIBLE GRINDER

A NEW universal convertible grinder has been placed on the market by the Warren F. Fraser Co. of Boston, Mass. The machine is designed and constructed to meet the exacting requirements of accurate grinding in connection with all classes of fine tools, jigs and fixtures, as well as general production work within its range. Special consideration has been given in designing the tool so as to retain its initial accuracy through a long period of service. All inner bearings of the machine are efficiently lubricated by a tube system with the oil pocket located at the front of the machine.

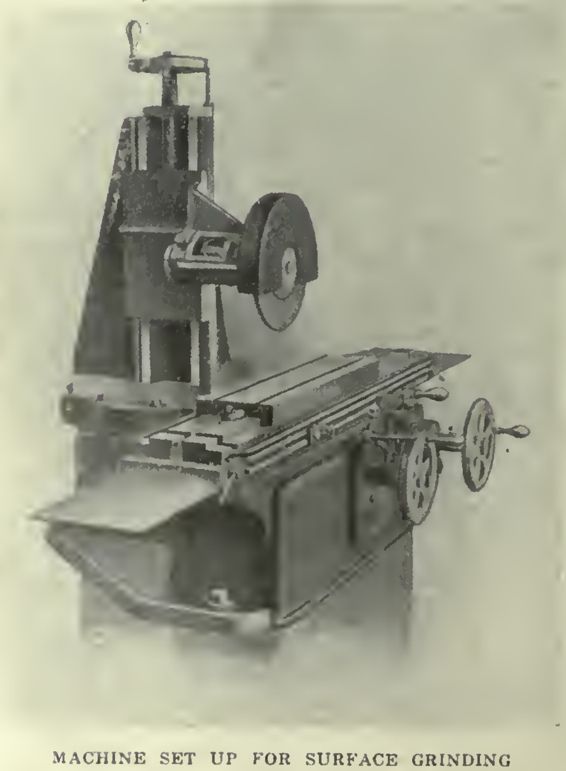
The head stock is of the swivel base type and its bearings on the carriage is of ample length to assure of perfect alignment when bolted firmly against the front edge of the carriage. The head stock spindle is hardened and ground and runs in bronze boxes which are adjustable for wear. The spindle may be set at any desired angle by movement of the swivel base and when grinding parallel work on the dead centres the head can be secured by means of a locking pin. The tail stock is fitted with a liberal bearing on the table, and like the head stock, is clamped to the front edge of the carriage. The spindle is hardened and ground and is operated by the lever action. The carriage is of substantial construction with long bearings on the bed, and fitted with a top table that swings on a central hardened and ground stud, and secured at either end by eccentric binding bolts. Graduated screws are provided for fine adjustment; a scale is also provided at the end to indicate the taper foot and the degrees of the angle.

The wheel slide at the rear is also provided with a swivel base that can be set at any angle, the edge being graduated in degrees. The handwheel actuating the slide is graduated to read to thousandths on the diameter of the work. The wheel spindle is hardened and ground and runs in bronze bearings adjustable for wear. The wheel spindle can also be placed at any desired angle in a horizontal plane, without reference to the angle at which the wheel slide may be located. The cross feed is automatic in its action, the minimum feed being .00025 inch per reversal of table. The machine is fitted with power traverse for the carriage, which operates smoothly and positively, assuring an accurate stroke to the table; the minimum stroke being ½ inch.

Two wheel speeds are provided, 2,700 and 3,800 R.P.M. Provision is made for the traverse table speeds ranging from 4 to 13 feet per minute. The work speeds are five in number, ranging from 130 to 660 R.P.M. The grinder has a capacity of 8 in. by 20 in. on cylindrical work, and 6 inches by 20 inches on surface work with a height of 8 inches, using an eight inch wheel. The machine is fitted with all necessary accessories and weights complete about 1,500 lbs.

A feature of this tool is it convertibilty from cylindrical to surface work. By replacing the ordinary wheel spindle—with its centre on the same level as the work

MACHINE SET UP FOR INTERNAL GRINDING



MACHINE SET UP FOR SURFACE GRINDING

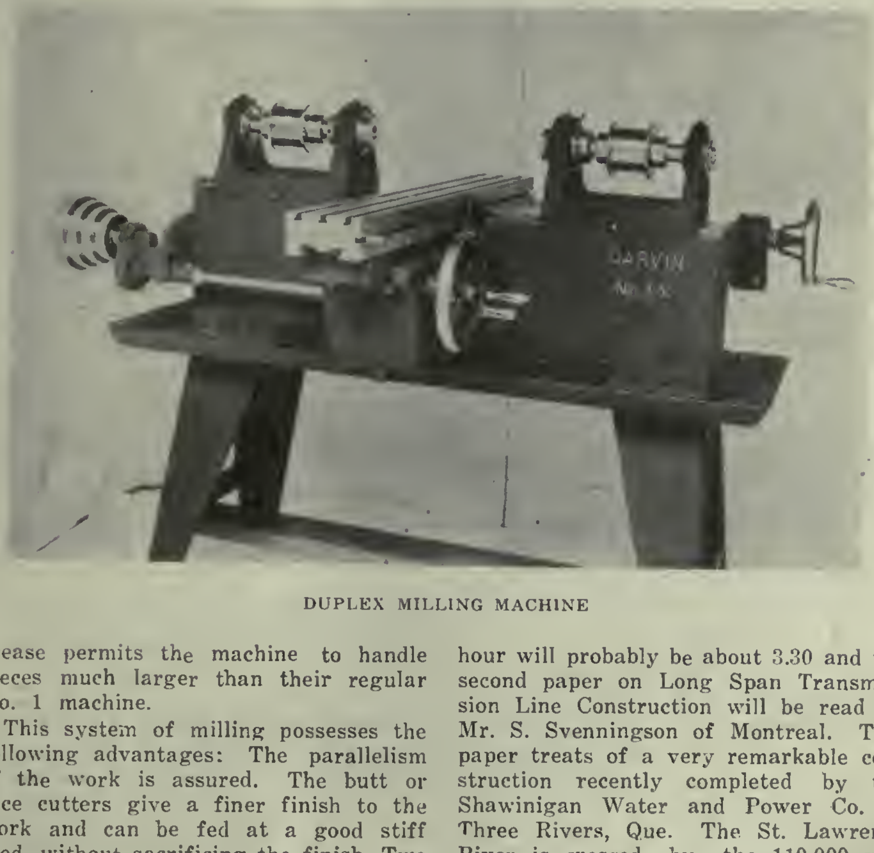
centre—by a specially constructed vertical slide, that carries the movable wheel slide, regular surface grinding can be performed. The spindle on this attachment is identical to that used for cylindrical work. The head for internal grinding is adapted for speeds of 18,000 and 25,000 R.P.M. The Geo. F. Foss Machinery and Supply Co. of Montreal, are the Canadian distributors for this machine.

GARVIN DUPLEX MILLING MACHINE

This is a recent addition to the Garvin Machine Co.'s line of duplex milling machines.

The machine as shown is provided with simultaneous wheel control to the spindle heads so that both heads may be moved at the one time. Provision is also made for independent head adjustment.

The feed of the table is thirty-four inches, while the distance between spindle heads is twenty-two inches. This increase permits the machine to handle pieces much larger than their regular No. 1 machine.



DUPLEX MILLING MACHINE

This system of milling possesses the following advantages: The parallelism of the work is assured. The butt or face cutters give a finer finish to the work and can be fed at a good stiff feed, without sacrificing the finish. Two sides of the work are finished at the same time. There is no scoring of the work such as is due to the drag and spring of straddle mills, as the cutters are close to the end of the spindles and there is no overhang. Work can be stacked up and the same operation taken on all at once.

The machine is designed to meet the requirements of economical and rapid manufacturing of standard articles, such as hardware specialties, brass goods, typewriters, cash registers, etc., the table having ample surface for holding fixtures, power feed, with automatic trip and quick return by hand wheel. Changes of feed are by cone pulley driven from countershaft.

This machine can be provided with pump and piping and is manufactured by the Garvin Machine Co., Spring and Varick street, New York City.

ENGINEERS MEET IN TORONTO

An event of unusual interest in the engineering field will occur in Toronto Nov. 22 and 23. The main Institute meeting of the American Institute of Electrical Engineers will be held in Toronto under the auspices of the Toronto section. It is expected that the members from the eastern States will arrive Friday morning and will be entertained at a luncheon in the Engineers' Club.

The afternoon session Friday will be opened by an address by the president and a paper will be read by Mr. Arthur H. Hull on Electric Power Development in Ontario. After the discussion the hour will probably be about 3.30 and the second paper on Long Span Transmission Line Construction will be read by Mr. S. Svenningson of Montreal. This paper treats of a very remarkable construction recently completed by the Shawinigan Water and Power Co. at Three Rivers, Que. The St. Lawrence River is crossed by the 110,000 volt transmission line wires on a span of nearly 5,000 ft. This is the longest span in the world. Due to the fact that the St. Lawrence is here navigable to ocean steamers, the clearance required is very high and the towers are 350 ft. in height. Since the membership includes many transmission line engineers a very complete discussion of this paper is anticipated.

An informal dinner will be held in the Engineers' Club at which a short address will be given by Sir Robert Falconer. The Friday evening session will include a paper by W. G. Gordon on the Electrical Equipment of the Canadian Northern Railway Tunnel in Montreal, tunnel and terminal electrification in Canada. The work involved in securing an entry into the City of Montreal required the driving of a four mile tunnel through the mountain north of the city and under the business section of the city itself. The 2,400 volt d.c. system was adopted for this electrification.

The following trips have been arranged for Saturday morning:

The British Forgings Co. This great electric steel plant, which is regularly operating ten six-ton Heroult furnaces, is believed to be the largest plant of its kind in the world. Installed in 1917 to fill the demand for shell steel for munition factories, a remarkable record was established by teeming the first melt within six months of the day on which the foundations were laid.

Leaside Munition Co. At present manufacturing shell for the United States Government. This is the largest and most important shell factory in Canada.

Hydro-Electric Substation and Labor-This paper describes the first extensive atories. The substation forms the terminal of the 110,000 volt line which enter the city from Niagara Falls eighty miles away. The present 75,000 kva. transformer capacity, together with the 50,000 kva. capacity in the substation of the Toronto Power Co. are the source of practically all Toronto's light and power. The laboratories, which are adjacent to the substation, are equipped for the many testing and standardization operations connected with the operation of a transmission and distribution system extending over a territory as large as New York State.

At 12.30 noon the visitors and reception committee will meet for luncheon at the rooms of the Toronto Board of Trade. This will be the final activity of the Toronto meeting. The New York train leaves at 5.00 p.m., but it is possible for those who desire to do so to leave on an earlier train and to inspect the work being done at Queenston by the H. E. P. C.

MUNITION WORKERS GIVEN INTIMATION

With peace at hand and the prospects of an early closing of a great many munition factories in Canada, the Imperial Munitions Board is advising all its employees who have chances now to drop back into permanent positions, to take advantage of them without delay. Cards on which are printed this advice have been posted up in many of the departments of the Imperial Munitions Board and before long the employees of all branches will receive this advice. The object is to get rid of those holding wartime positions on the Imperial Munitions Board by degrees.

IT'S RIGHT UP TO YOU

THERE'S a larged sized chance of the word "reconstruction" becoming a sort of a hackneyed phrase. The word is all right and it states the case, but from much use, if nothing else, the danger comes of its being accepted as meaning very much in general and nothing much in particular.

There is the danger of it becoming so general that it will fail to come home to the individual. After all the work of reconstructon has a very pointed personal application.

The work of reconstruction is primarily the task for the men who have stayed at home. The men who went overseas have done their part. They have paid their price, and now it is up to the homesters to show that they are none the less worthy than the men who went overseas. It may be, even in its worst stages, simply the case of putting up dollars where a few months ago men were putting up lives.

There are firms in Canada that have made money out of the war. They have made thousands, millions. They have stacked up more money than they ever thought possible on the basis of their old lines. They have been doing this while others, brave, strong men, were getting shot at on the battle front. These firms have been enabled to make their millions because these men were courageous enough to go to the front, and having got to the front, to stay there, through all the horrors of war, the slime, the mud, the rain, the frost, the rain of shells and the barrage of steel. All the powers of hell couldn't drive them out. They stuck, and because they stuck the security of the industries at home was protected, and out of this grew the big earnings of the war plants.

Don't think that we lose sight of the triumphs of Canadian skill in mastering the problem of quantity production of shells. Without the shells the man at the front would have been helpless. But the man at the front took the long chance and the $1.10 per day.

Now some of these firms have surpluses from war operations. They are not imaginary surpluses. They are real. They are not dependent on methods of bookkeeping. They exist in a very definite form. They are liquid assets. What is going to be the attitude of the directors and the stockholders? Two ways lie open to them:

(1) This money is an asset that will continue to pay dividends during a period of uncertainty. We can sit tight on it and dribble it out until things come back again. We can refuse to allow it to be used for the development of lines that carry a degree of financial doubt as to their earning capacity. We can play safe with a fund that was piled up while others were staking their all on the western front, or

(2) This money came to us from an abnormal source. It was from the making of munitions. It was our part in the fight. We had the easy time of it while the man in uniform took the raw end. Now that man is coming back and we can use this fund to see to it that conditions are such that he will be able to secure decent employment at a good wage. He will not want charity. He does not ask for a hand-out. He simply will expect that his service at the front will entitle him to the right to live, and to participate in the distribution of monies that were piled up by reason of his devotion to a cause.

That in brief, is the situation. The first option is not reconstruction. It is plain destruction, commercial and national. The second is reconstruction in the real meaning of the word.

There is danger, as stated above, that much use of the word will take from it the point it should carry, will dull the personal touch in it, and make it such a dry-bone affair that it will live only within the covers of government blue-books. If it gets there the word "Failure" will be written over the country just as plainly as the word "Victory" was flashed across the Allied skies a few short days ago.

Reconstruction is real. It means **me**. It means **you**. It doesn't mean simply an academic matter to be spoken of in long syllables. Get this into your mind no matter whether you are a laborer, an employer or a stock holder. "This business is my own concern. There is a part in it for me, and if I don't do it no person else will." Don't jolly yourself into thinking that you can lean back and simply be a spectator in this last great act of the world's greatest drama.

Our idea of hard luck is for the sleeping car porter to lose his whisk before he has made the final round-up of his victims.

It's to be hoped that the peace delegates do not spoil the victory that has already been won by the soldiers on the field.

There will be more wire nails made now. All of which will be quite a source of relief to the bachelor who regards wire nails as his legitimate prey in lieu of pant buttons.

The Germans are now proceeding to surrender their fleet. It should be about as good as new as the British didn't have much chance to muss it up during the four years of war.

The Kaiser went to Holland but is not going to stay. They say he's returning to Germany. If they really want to know how to dispose of him why not turn him loose in one of the Allied countries?

In writing to CANADIAN MACHINERY in connection with a business matter, Wm. J. Kirkham, of Renfrew, says: "I must mention that I am pleased with the quality and variety of matter contained in your CANADIAN MACHINERY; it is sure to become more and more popular with the general classes of mechanics in this country."

PULL THE MEN NEAR YOU UP WITH YOU

Superintendent of the Massey-Harris Co., Toronto, Works Has Had Wide Experience

By A. H. T.

EXPERIENCES of R. W. Gifford, Assoc. Mem. Am. Soc. M. E., go to show that ability to see through the peeling to the fruit pays handsomely. In other words, elusive opportunity struts disguised in all togs, in even the made-in-America raiment of a Pharaoh.

Gifford, at the age of 35, is superintendent of the Massey-Harris Company's Toronto works. His story, as I recall it, follows:

"From when we were knee high," he said, "it was drilled into my brother and I that we should have a college education. Not the easy matter you might suppose; for my father was a minister and ours a good home, a Canadian home up till the year before my birth, but a home in which there was never a plentitude of money. I know I had but forty-three dollars, and I think my brother had forty-eight, when we left for Ann Arbor to attend the University of Michigan.

R. W. GIFFORD
Superintendent, Toronto Plant
Massey-Harris Co.

"The following four years we missed some of the fun, all right. But I believe we learned to do one thing that college boys, as a rule, know nothing about after graduation; we learned to stand on our own feet. Two summers we went out on railroad construction work and in one way or another we paid our way through the University without another cent from home.

"I was twenty-three years old when we graduated in 1906. We had both studied engineering and we went together into the shops of the Olds Gas Power Company, of Lansing, Michigan. We entered on a two-years' apprenticeship at the inconsiderable wage of seventeen and one-half cents an hour, but within the two years we had worked in every department of the shops, and this work had seemed but a continuation of our studies.

"In January, 1908, the secretary-treasurer called me into his office and asked if I'd help him out for a few weeks. His was such a desk as this," Gifford said, indicating his own flat-topped, expansive oak. "He sat at one side and I at the other. And as the books of the company were open to me, mine was a fine opportunity to study financing of business.

"Until November, 1908, I was assistant to the secretary-treasurer, and then made export sales manager. This position itself was at that time created. I was told to rely on my judgment and to work out my own salvation.

"I went South in April, 1909, with an unlimited drawing account and a letter of authority from the Olds Mobile Company as well as credentials of our firm. My duties were more to make a study of conditions in Mexico, Cuba and all South America than to attempt actual selling. I had but two calls to make, as a matter of fact, but I managed to sell more than enough goods to pay all expenses.

Massey-Harris Everywhere

"Incidentally, it was on this trip that I first came into contact with the Massey-Harris Company, Limited. I ran into "Massey-Harris" everywhere, and as they at that time sold Olds engines, a number of the orders I booked specified that shipments should be made through "Massey-Harris."

"One day after my return to Lansing, an Egyptian prince called at our plant, and as his request seemed to be in the nature of export business, he was turned over to me. He was being educated in the States and it appears that his father, a very wealthy Egyptian, had written him that a—I guess you'd call it a plague—was killing off so many oxen there was danger of the land going unplowed. He had evidently told the son to ship him an American self-propelled plow.

No Tractors Then

"But at that time, at least to my knowledge, there was no such thing. However, assured that cost would be no objection, I asked for authority to build a machine for the prince, and I was told to go ahead, but to have it built outside our shops.

"By the last of April, 1910, my tractor was ready. The boys dubbed it 'Gifford's Little Egypt.' My brother went with it to Egypt. Incidentally, as our outside man, he was travelling the world over for export business, which had grown from six engines sold the year prior to my appointment as export sales manager to more than twenty-five per cent. of our total business.

"It so happened that K. H. Deyo, head of a firm at Binghamton, N. Y., which jobbed Olds engines, was in Lansing and saw 'Little Egypt' turning furrows. Later the same day he came into my office.

"'Gifford,' he said, 'I'm going into the manufacturing business and you're going with me.' As this was our first meeting, his was a snap judgment, of course. Nor was I prepared to say either yes or no to his proposal.

"That evening Olds employees were banqueted, and K. H. Deyo sat opposite me at the table. The president's address helped me to a decision; for he dwelt on the desirability of each employee recognizing the limitations of his position—the fact that one could not hope to be more than a cog within the wheels of an organization such as the Olds Gas Power Company. Deyo and I exchanged glances of mutual understanding. I'll be down to see you this coming Saturday, I told him.

"Within a month I was in Binghamton superintending the erection of the Deyo-Macey Engine Company's plant. I designed their complete line of engines.

"And I remember how it occurred to me that soon or late there would be a break between the Olds Gas Power Company and the Massey-Harris Company, Limited. I planned accordingly.

"The break came in 1913. Private—very private—news of it was still ringing in my ears when I reached Toronto. At the Massey-Harris plant, however, I was told that nothing of an intended split was known—so I asked that we be remembered should anything develop, and returned to Binghamton. In March the Massey-Harris company bought out Deyo-Macey body and soul.

"I stayed as superintendent until the first of the year 1914, when I was made secretary and general manager of the Binghamton plant.

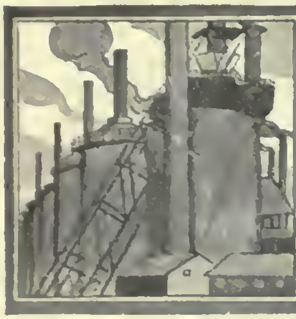
"In December, 1915, I was called to Toronto and given charge of the Massey-Harris shell plant. When we completed our shell contracts in October, 1917, I was made superintendent of these Toronto works."

"And your brother?" was asked.

"You may have heard of the Gifford Engine Company, of Lansing, Michigan," was the answer to our query.

Gifford says: "Take the open door and as you go up, **pull the men near you up with you.** Then if they are loyal and you yourself are fundamentally honest, you are pretty sure to succeed."

Some time ago the Massey-Harris Company, Limited, subscribed to CANADIAN MACHINERY for twenty employees. We cannot say that R. W. Gifford had a hand in that, but knowing the value he places on technical education, we think it probable.



MARKET DEVELOPMENTS

Canada's Part Can Hardly Be Exaggerated

Dominion Has Been the Most Successful Shell Producing Country in the Business—Steel Market Holds Firm, While the Scrap Metal Dealers Are Practically Out of the Market

MUNITIONS business is practically at an end as far as the sale of machinery is concerned. There may be some business yet in connection with American orders, and Canadian firms are sharing in it. In fact one firm was shipping this week on an order it had secured for a quarter of a million in equipment, delivery to be made at an American shop.

Canada's record in the output of munitions is one that can hardly be appreciated. This country has been the outstanding success in the turning out of all sorts of munitions and fuses. In the making of airplanes as well the record has been well sustained.

The disposal of the machinery that has worked in shell shops is a big problem. This machinery divides into three parts—(1) the single-purpose machines that are good for nothing but certain shell operations; these will be scrapped; (2) standard machinery that has been fitted with special attachments for the turning out of munitions—these fittings can be stripped and the machine brought back to its original capacity and style; (3) the general purpose machinery that has been used will, if it has withstood the working of continuous operation, be used in regular production and shop practice again.

There has been a slight reduction in the warehouse price of plate. The price is to-day put at 8c per pound, as against the 10c mark that has prevailed for some months. Ten cents was a fictitious price, and even eight cents is a figure that cannot be maintained when steel gets on a competitive basis once more.

Scrap metal dealers are practically out of the market this week. They do not want to buy anything because they cannot see where they are going to find a ready market for it, and it would be suicide for them to buy for stock out of the present high market and run chances of disposing of their material in a lower market.

There is a tendency on the part of many whose previous training has fitted them only for laborers to want machine positions in the shops now, relying on their war work experience to see them through. In some cases they may be able to do this, but it will not be on work where the training of a machinist is required.

HAILROAD BUYING SHOULD BE HEAVY IN THE VERY NEAR FUTURE

MONTREAL, Nov. 21.—While no immediate cessation of industrial activity is anticipated, the manufacture of munitions in Canada will soon be a matter of history. Plants working on the British shells have received instructions from the Imperial Munitions Board to immediately stop all forging of shells, and plants are given until the 14th of next month to clean up on the machine work, and on this date the production of British shells will cease. Plants working on American contracts are continuing as formerly, as no instructions have yet been issued to suspend operations. Lyalls, who have a large contract for 155 m.m. shells, fully expect to operate throughout the winter, as no announcement has been received to the contrary. This plant has just about completed the installation of equipment and capacity production will soon be attained. It is thought that a large number of men will shortly be required for various branches of government work, including general construction and shipbuilding. An encouraging note is sounded in the remarks of Hon. A. K. Maclean when he states, "There would not be, he believed, the sudden transition and the sharp dislocation of industry, and consequent unemployment and unsettlement that many people seemed to fear."

Peace Affects Steel Production

Production of the early future steel situation is still more or less a matter of guess work, owing to the apparent obscurity that surrounds the general market. That an easier condition will soon be evident is conceded by many, but to what extent is very problematic. Considerable disorganization marks the present progress of events and as a result the situation is very unsettled. This disturbing factor has created a feeling of nervousness throughout the trade and business has been conducted in a very guarded manner. A feature of the armistice has been the reactionary effect upon the munition activity here and many plants are preparing to finish up on their shell work. The steel foundries here have stopped the making of shell billets and forging plants will soon be closed. The railroads are anticipating a renewal campaign, as they have virtually been starved for nearly four years. Rolling stock and supplies have reached a low ebb and expansion is only a question of market conditions. While it is felt that something must be done in the very near future, it is not likely that decided action will take place until some readjustment has been made in the cost of material. Dealers here look forward to a better supply market with lower price quotations. The stoppage of munitions and steels for destructive purposes will undoubtedly react on the general situation as increased raw materials will be available for such mills as have been pressed for supply. The conversion of some bar mills to the rolling of narrow plates will result in considerably more plate production and a return to lower plate quotations. The situation here, however, has shown little relief and the regulations respecting plates prevent dealers from acquiring material for warehouse storage, even should they desire to do so, which few are anxious to do under the present circumstances.

Lower Levels in Metals

Recent events have been an influencing factor in the metal market, but developments so far have not affected price quotations to any extent. With the American fixed price on copper still effective the local quotations will remain firm, although the demand is a little lighter. The tin situation here is rather obscure, owing to inability of getting cables through from London. Shipments of metal are better, but without definite information the market here remains firm. A decline of 2 cents puts the current price at 88 cents per lb. Spelter and lead are both unchanged at 10½ cents per lb. Antimony demand has fallen off and price has declined 2 cents to 13 cents per lb.

Machine Dealers Optimistic

It is quite natural to assume that confusion must reign for a time following the events of the past week, but the optimistic spirit of the machine tool dealer is still a feature of market conditions. It is true that the demand for shell machinery is now a negative quantity, but the inquiries for general equipment that are still coming in does not imply a dormant state of industry. Dealers here report that an increase of inquiries has been noted for tools for marine work, as it has been intimated that some plants that have been engaged on shells may be turned over for the moking of ship accessories. The difficulty of getting tools from the States is still a factor and maintains the high cost of past transactions, but with the weaker demand for shell and ordnance requirements it appears only a question of a short time until the machine tool trade will take on a more normal appearance. In speaking on the possibilities of the single purpose machine after the war, one dealer here thought that there would be a much larger field for such tools, but would probably be restricted to industries where relatively large quantities of uniform product was produced. A feature of the week has been the increasing volume of second-hand tools available and these can invariably be secured at more reasonable figures than formerly. A notable falling off has been shown in the general demand, particularly during the past week. For some time munition plants have been adopting the policy of hand-to-mouth buying and would seldom consider large orders. The shipbuilding interests are still heavy buyers.

Scrap Adjustment Likely Soon

The closing down of shell activity has added to the disorganized state of the old national situation and dealers report a very quiet market. With the copper price still maintained this loss of scrap will likely continue firm for the remainder of the year. Dealers state that much scrap is available, but without a market for it they are not interested, as it would be very unwise to stock up at prevailing prices. They intimate, however, that within the week some readjustment to lower levels are very probable. Present quotations may be considered as nominal.

MUNITIONS BOARD CUT OFF QUICKLY

Sent Cancellation Orders Right on the Heels of Armistice Signing

TORONTO.—The machine tool trade, in common with other industries that were very much influenced by war conditions, has turned from war trade to a very large extent. The reason is that the war trade is nearly a thing of the past, a few American orders being about all that are available now. Other orders, especially from the British Government, are ebbing out in order to disturb the labor market as little as possible. The Munitions Board, had they followed the law of need, would have cancelled the contracts at once, because they do not want or need any more munitions. However it is better policy to shut off by degrees, even if it does cost more money.

There are several questions discussed this week regarding the disposal of war plants. One suggestion is that the government should pick up from the great amount of special machinery, complete plants for making the different kinds of munitions, and store it away as part of the policy of preparedness. It is pointed out that Canadian shell shops know the business thoroughly, and the best of their equipment would be a good investment for the government to keep on hand in some of the arsenals. That is one of the suggestions put forward by a leading dealer.

Plate and Sheets Down

One Toronto warehouse quoted \$8 on plate this morning. That is a direct cut of 2 cents per pound, as \$10 has been the prevailing price for a number of weeks now. This move was not due to any great improvement in the purchasing conditions, but rather was it the outcome of a desire on the part of the trade to get below the \$10 price for plate, which has been more or less of a fictitious value for some time past. Some of the mills on the other side, explained one of the steel dealers here, seem to be in the position now to do the milling if we can go ahead and secure the licenses.

Whether steel prices will find a lower level or not is a debatable question. The case of a concern that produces both pig and ingots serves to illustrate the case. In some cases the yards are full of ore, bought at war prices, which are high. Pig iron can't take much of a slump until that high-priced ore is worked out. The same thing applies to the open-hearth furnaces. High price pig and high price scrap are not going

POINTS IN THE WEEK'S MARKET SITUATION

The steel and coal plants in Nova Scotia have to a large extent been on a peace basis for some time, and no trouble is likely to happen there on the falling off of war orders.

—

It seems likely that orders in this country for 155-mm., 12-inch and 240-mm. shells will be completed. British orders have been cancelled and operations will be entirely suspended in a few weeks now.

—

One Toronto machine tool dealer suggests that the government should take over enough out of the best in the shell plants to be able to turn to shell production any time if the need arose.

—

Montreal reports that the railroads are likely to be very heavy purchasers of machine tools and other equipment, as their supply and repair departments have been starved for months past.

—

Steel plate was brought down to 8c in Toronto warehouses this week, being a drop of two cents. It is still selling here well above the price fixed at U.S. points.

—

Several of the larger dealers in scrap metals report that they are out of the market this week. They will not buy for stock as they anticipate an era of lower prices before very long.

—

Some of the machine tool dealers find themselves quite heavily stocked with supplies that are not good for anything but shell operations. They had carried heavy stocks in order that shell shops could be speedily supplied. The high speed steel in them will bring about 1-16 of the real price.

to be melted and turned into cheap ingots.

The sales end can argue forty different ways to make it apparent that there is not going to be any increases for some time. Against that, though, there is the fact that the purchasing agents are beginning right away to inquire about lower prices, and between these two extremes the real situation will come to the surface in due time. There is nothing in sight at the moment, though, to indicate much depression in price.

A drop is noticed also in the price of sheets. They are now quoted at $9 per hundred, against $10. In fact some of the warehouses have been giving quotation at $12 during the past few weeks. The supply has not appreciably improved. There will not be much betterment in the supply of sheets until the plate programme gets cleared away. Many of the sheet mills have for some time been rolling plate and they are still doing this.

There is a feeling in the steel trade that the War Trade Board should continue in office for some time yet, as the War Industries Board at Washington is doing. It is felt that this would have a sobering effect on the whole situation, and that the government, in this way, could act as the pace maker in the matter of prices. and see that no hardship was worked on any particular dealer.

The Machine Tool Business

Machine tool dealers are turning to other lines than war work. Cancellations have been made in several instances. In fact about the first of these came from the local branch of the Imperial Munitions Board, and in such a way as to throw the dealers into a position where they stand a chance of losing money. The notice sent from the Imperial Munitions Board carries the following clause:

> "If shipment is made after receipt of this advice, same will not be accepted at our stores, and it will be necessary for you to arrange disposal."

That means that a dealer, who may have purchased a machine at some point in the United States, is put in the position of having to secure an immediate cancellation at the point of shipment or bear the loss if he cannot do this. Dealers do not like this idea, and they claim that the Imperial Munitions Board is the one concern that should act, in a time like the present, with a great deal of moderation and tact. The armistice was signed on the 11th, and on the 12th the cancellation notices were sent out.

Several of the munitions firms have inquired of the dealers if they will take back certain supplies, such as hobs, chasers, etc. The dealers have no use for the stuff. For instance a hob that has been selling for around $16, will now be worth about $1 for the high speed steel that is in it. because there is no commercial operation that calls for the use of such a tool. The opinion is put forward in several places that the loss thus saddled on the dealers, the munitions contractors and all handling or using these special purpose supplies, should be absorbed by the trade in general, or in some other way. Had dealers refused to keep a big stock of hobs, etc., the contractors would have been up against it all the time. On the other hand the carrying of a large stock of hobs and chasers enables production to be kept at a high standard. So it is that the dealers, under present arrangements, who carried the large stocks and were always ready to supply the shops at short notice, are going to suffer from their enterprise.

A limited trade is still being done in supplies for shell shops, but the buying is being kept in very close bonds at present. It appears that contracts in this country for the 155-m.m., 12-inch and 9.5 are likely to last for some time yet.

Out Of The Market

"We are out of the market." That was the way in which Frankel Bros. sized up the situation early in the week. "By that we mean that unless we have a destination immediately available we are not buying."

If that position is taken by many of the large dealers in scrap it may have a tendency to force prices to a lower level, especially in sales where necessity figures to any extent. Buyers admit that prices, quoted elsewhere in this issue, while nominally correct, are apt to be misleading because they do not represent the actual money that they are willing and prepared to pay at the present time. Casting copper is weaker in New York, and sales have been made at 24c. This, dealers point out, has a tendency to weaken other prices as well.

Other yards intimated that it was necessary for them to move with a great deal of care. They are looking for a lower level of prices before very long, in fact any purchasers who come into the market, talk lower prices the first thing. "Under present conditions we are not going to buy a single pound of material for stock," was the way another dealer sized up the situation.

SCOTIA PLANTS HAVE BEEN ON PEACE FOOTING FOR MONTHS

Special to CANADIAN MACHINERY

NEW GLASGOW, Nov. 21.—The sudden close of hostilities has set everybody to thinking of normal business and the problems that will attend upon the readjustment from a state of maximum war production to peace conditions. One reassuring feature is that the allied governments have had the problems of demobilization and reconstruction under consideration for a long time, and the rapidity with which the Dominion Government took action and called to Ottawa for consultation the heads of representative industries is an encouraging sign of the readiness of the responsible authorities. Before the armistice was actually signed the heads of Canadian steel companies, railroads and car manufacturers were summoned, and on the day following the cessation of fighting a meeting was held in Ottawa to consider ways and means to turn the manufacturing facilities of the country into ordinary channels of production.

The neighbourhood of New Glasgow contains important railway connections, collieries, steel-works, foundries and a car plant, and it is thus a microcosm of the coal and steel industry and its offshoots. The production of munitions has been a declining factor for many months. For example the employees of the Nova Scotia Steel & Coal Co. now number not much more than half of those employed in 1915 and 1916, and for several months past it may be said that this company has been operating on a peace-time basis. Its plant at Trenton is particularly adapted for the production of ordinary commercial steel products, such as light rails, railway spikes, bolts and nuts. angle iron, structural steel, plates. The manufacture of heavy forgings is a speciality of this plant, and it will be seen that with the demand that is anticipated for railway materials, marine forgings, and building material, there is no reason to anticipate any severe readjustment occasioned by the cessation of munition orders which must naturally now take place. The railways have been starved during the past few years in the matter of rails and rolling stock, and it is further anticipated that there will be a brisk demand for railway cars, and for freight car and locomotive axles, both of which the Nova Scotia Conpany and its subsidiary the Eastern Car Company, are equipped to supply.

At The Dominion Corporation

At the plant of the Dominion Iron & Steel Company in Sydney, the production of shell steel has for several months past been practically discontinued, and the steel output has been largely absorbed in the making of steel rails for the Canadian Government railways. A continuation of this business is a certainty of the near future. The new plate mill, now under construction, should not suffer for lack of orders in view of the tremendous shortage of ships that exists, and must exist for a long time to come, despite the most strenuous efforts of the shipyards. The problem of feeding in Europe does not appear likely to be lessened by the cessation of fighting. It may indeed be intensified by reason of the disorganization of the Central European states, and until the harvest of 1919 is gathered, Europe must largely be fed from this side the Atlantic.

The coal supply question promises to remain acute for some time to come. The production of Nova Scotia is now 31 per

(Continued on page 62)

How Marine Cylinders Are Moulded and Cast

The Imperial Munition Board Programme Includes Some of the Largest Marine Engines Ever Built in Canada

By F. H. BELL, Associate Editor

THE molding and founding of cylinders is a subject which never grows old. The art of molding and the science of founding are no where better exemplified than in the production of this class of casting.

As our heading would imply, the class of cylinders to be dealt with in this article is that called for in the orders from the Imperial Munitions Board, to be used on the engines of the ships being built for Canada's new merchant marine.

When it is remembered that the cylinder constitutes the real power of the engine and is depended on to propel the ship thousands of miles from land, it will be readily understood that it must be without blemish.

It must be composed of clean, sound, close-grained iron which will bore out smooth, and be free from defects of any kind either as regards material or workmanship, and lastly it must undergo the pressure test and be O.K.'d by the Marine Underwriters' inspector. From this it will be easily appreciated that every one who is in any way connected with its construction is directly responsible for the results. The quality of the metal purchased, the purity, of the fuel used in the melting of it, the manner in which it is melted, and the temperature at which it is poured, coupled with the skill of the workmen who perform the work of molding and core-making, and the untiring efforts of the superintendent and foremen who see that workmen are provided with proper equipment and material, all contribute to the success or failure of the casting.

Through the courtesy of the genial Mr. Wingate, general manager of the Gurney Foundry Co., and Mr. McCormick, the general superintendent, we are enabled to give a fairly detailed description of how this intricate class of work is done at their plant in West Toronto.

The method adopted is similar to that commonly employed in molding stationary cylinders. The pattern is parted in the middle and molded and poured lying on its side. Complete iron flasks are used. These flasks are one inch in thickness and well reinforced with ribs. They are all interchangeable and range in size from 9 feet square down to any size required for smaller cylinders.

Trunnions are provided for convenience in rolling over. Permanent pits are provided some 12 ft. square and 5 ft. deep in which to make the mold and pour it. These pits are not used in the ordinary sense of foundry pits, but are simply used to bring the mold down low enough for convenience in molding and pouring, as well as providing backing for braces to support the mold against straining under pressure of metal while being poured. The space between the flask and the walls of the pit, allows ample room for the workmen to walk about while working on the drag, and the walls also provide good foundation for scaffolding while ramming and finishing the outside of the cope. Before proceeding further it is as well to explain that these molds are all made in dry sand. The facing used is composed of 3 parts old molding sand and 1 part new, mixed in the proportion of 12 to 1 with black core compound, to which is added a keg of pine saw-dust for a batch big enough for one mold. No flour is used; the black compound taking its place, but thin clay wash is used with which to temper it. In beginning to make the mold the smooth follow board is placed on the bottom of the pit, and the bottom half of the mold proceeded with as in all green or dry sand work. The pattern and follow board are covered with a few inches of facing sand and well rodded and nailed wherever a rod or a nail can be utilized to any apparent good purpose, after which it is backed up with heap sand, and properly rammed and vented. A staunch iron plate an inch thick constitutes the bottom. This is bedded on and pounded to a perfect bearing with a sledge and securely bolted, after which it is turned over by means of a powerful pneumatic crane, in less time than it takes to tell the tale. The cope is rammed up in a similar manner and lifted off by this same pneumatic crane and rolled over on its back.

FIG. I—Drag for 54" low pressure, slide-valve cylinder. Note clay balls on bottom of barrel to show thickness of metal after trying in core; also chaplets separating steam chest and port cores.

The patterns are drawn with the crane after which the mold is finished and black-washed placed in the oven and is thoroughly dried. These molds are not skin-dried but are dried from top to bottom, making a hard, open-grained, yet smooth-faced body for the iron to lie against, equal in every respect to a loam mold. The saw-dust opens the pores of the sand similar to a loam mixture, while the compound and the clay wash hold it firm. After being dried and sufficiently cooled to be handled, the drag is returned to the pit, where it is rubbed

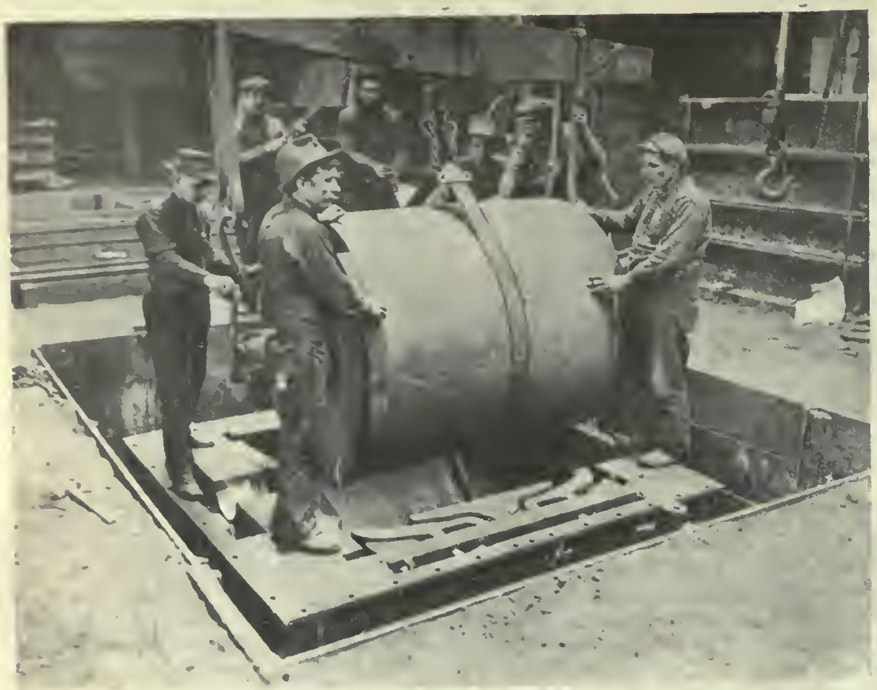

FIG. 2—CORE BEING LOWERED INTO PLACE. SEE COPE TO RIGHT SHOWING MANNER IN WHICH SECTIONS ARE BUILT TOGETHER, ALSO SHOWING SYSTEM OF VENT HOLES.

perfectly smooth by means of waste, soaked in coal oil, and finally finished with dry plumbago. It is now ready to receive the cores which form the interior of the cylinder as well as the various ribs and branches on the outside.

Fig. 1 shows drag for low pressure slide valve cylinder with bottom half of steam-chest and port cores, also bottom half of core which forms the flange for stuffing box, as well as the ribs for strengthening lower head of cylinder and the brackets which support the cylinder on the upright columns. Fig. 2 shows main core being lowered into place in the drag. Fig. 3 shows top half of core being lowered into place, showing how end of cylinder will appear. Figs. 4 and 5 show different views of high pressure cylinder, showing it to have round piston valve.

The making of the cores is of equal importance with the making of the mold. The sand used is pure sharp sand, brought from the shores of Lake Erie and is mixed with linseed oil in the proportion of 1 to 16.

The making of the main core shown in Fig. 2 is of interest. It is made in halves, being swept up on flat plates and dried, after which it is carefully jointed and pasted, appearing as in Fig. 2. The arbor shown in Fig. 7 is placed on the plate and filled tightly with coke, after which the core sand is rammed around it until it is of a sufficient size to be swept to the exact shape and dimentions. The bolt holes marked A.A.A., Fig. 7, are used to bolt the two halves together, and when bolted in three places it makes a core as rigid as though it had been swept on a barrel arbor. The other cores are made in core boxes from the same mixture and are suitably rodded and vented. This is not difficult, as the oil cores are strong in themselves and when burned, very little gas is generated.

The setting and securing of the cores, is undoubtedly the most particular part of the entire job. They must, not only be properly placed but must be secured against being shifted or floated by the force of the incoming metal. The system adopted by Mr. James Douglas, who has charge of this department, assisted by his able aide, Mr. A. E. Scott, leaves no room however for fear. To demonstrate more clearly we will go back to the ramming of

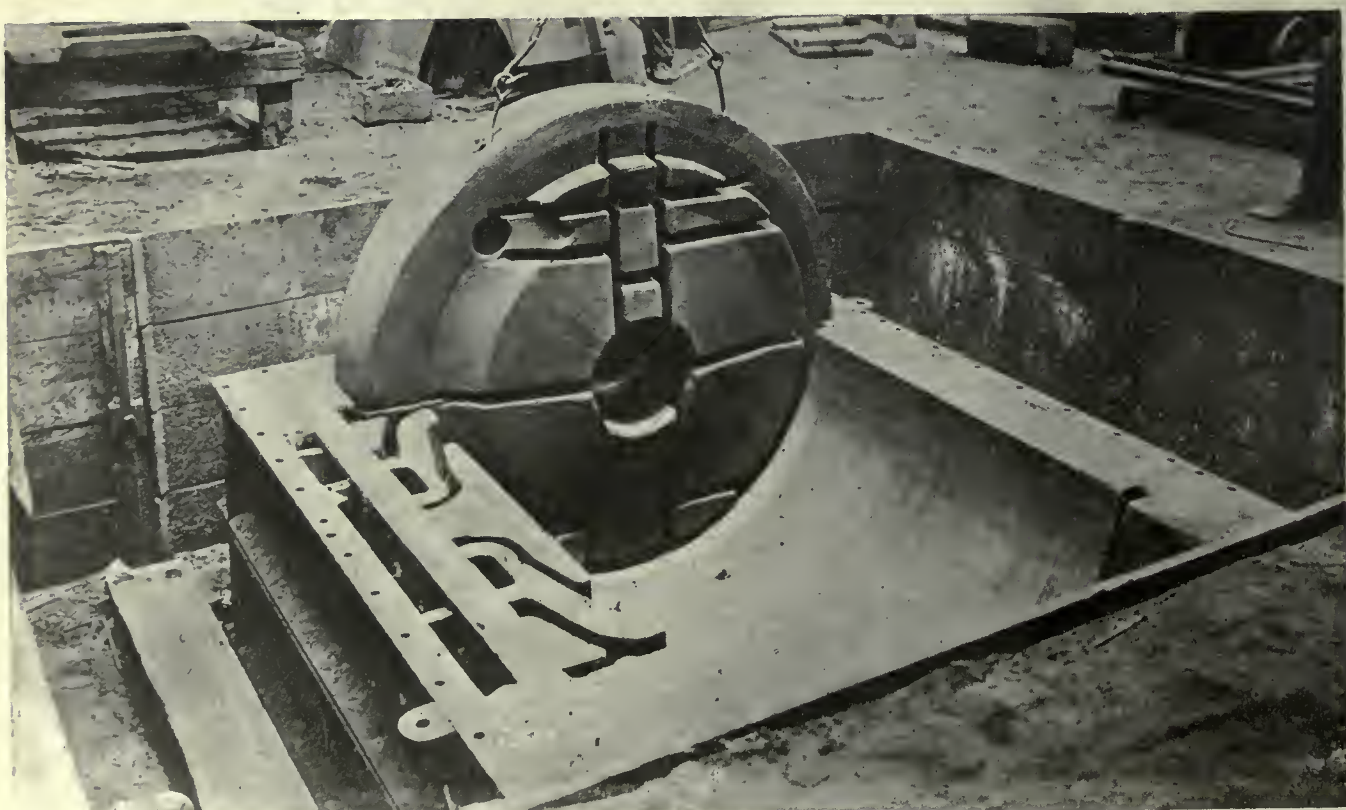

FIG. 3—TOP HALF OF HEAD CORE BEING LOWERED INTO POSITION TEMPORARILY. STUD CHAPLETS IN BARREL IN PLACE OF CLAY BALLS, ALSO SPACE BACK OF CHEST CORE TO FACILITATE TYING CORES INTO PLACE AS WELL AS ALLOWING FOR ESCAPE OF GAS FROM CORES.

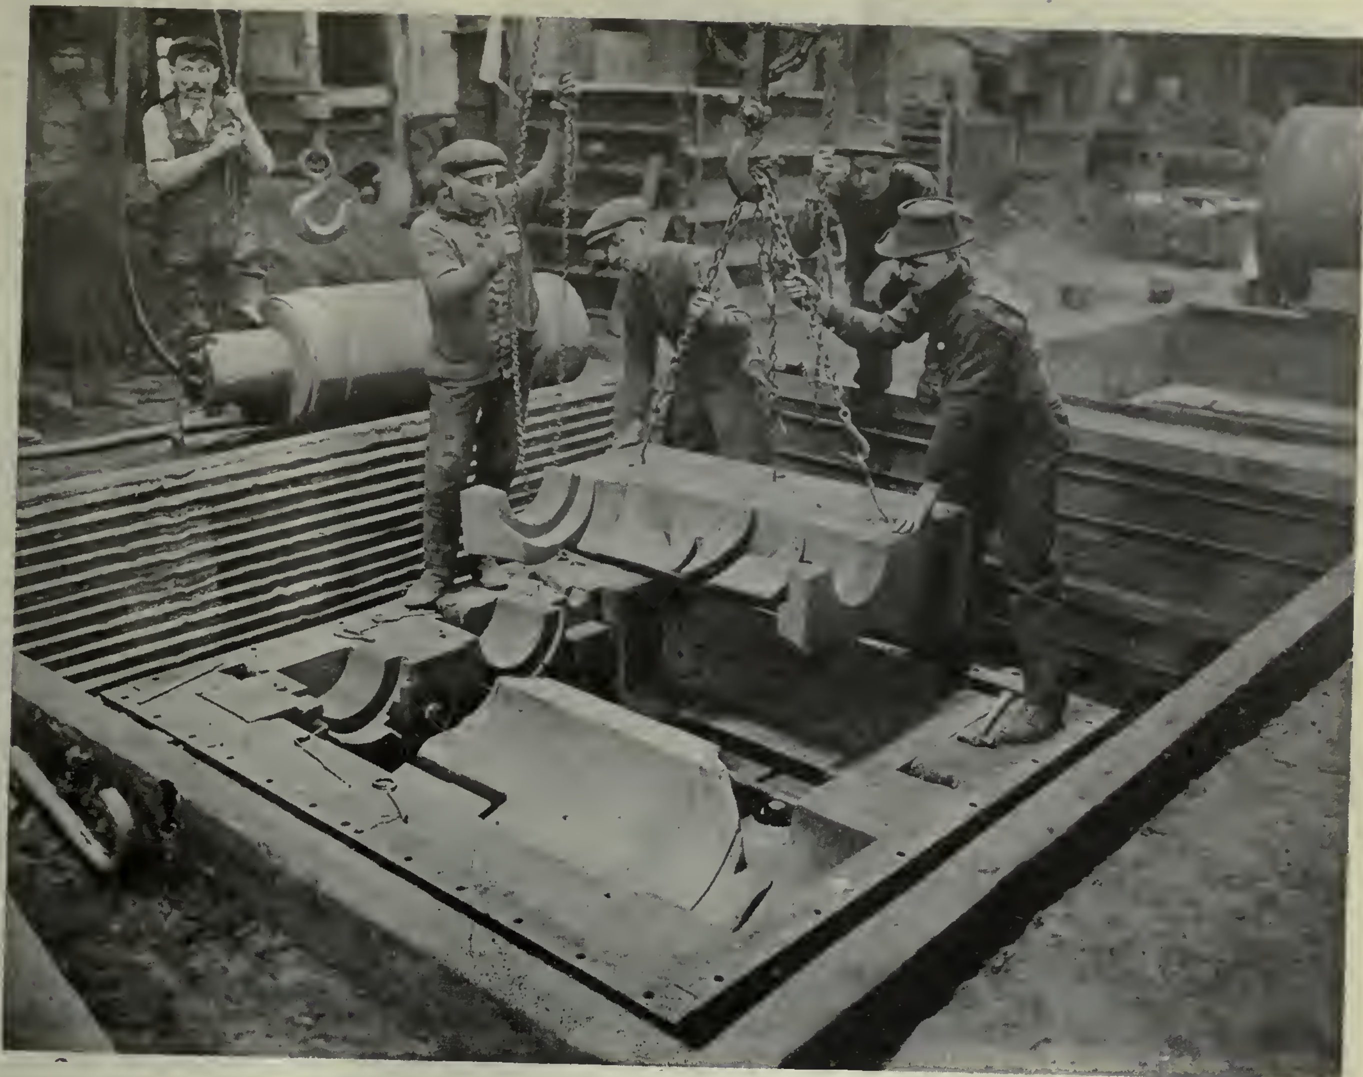

FIG. 5—CORE BEING LOWERED IN PLACE IN DRAG OF HIGH PRESSURE PISTON VALVE CYLINDER.

the drag. It might be explained that the drag has bars similar to the cope to assist in resisting strain. While the half pattern and the drag were on the follow-board preparatory to starting the mold, irons are placed tight against the patterns wherever a chaplet will be required and securely bolted to one of the bars. When the pattern is withdrawn later on, these irons will be seen even with the face of the mold. When setting the cores, balls of clay are placed on these irons, and the core is tried in, temporarily; by so doing the clay balls are pressed into exact thickness required, and a stud chaplet of the size indicated by the clay is placed upon the iron in place of the clay. Stud chaplets are also tightly fitted between cores and side of mold and also between the cores themselves.

In addition the port cores and the steam chest core supporting them are securely tied through the back of the steam chest core-print and onto the outside of the flask. The top half of end core, shown in Fig. 3 is not put into that position until after the main core is placed, when it and the top halves of the steam chest and port cores are put in their proper position and clay balls placed wherever a chaplet will be. The cope which also has irons fastened to the bars to hold the chaplets is now tried on and lifted off and the proper sized chaplets put in place to hold the cores down, and also to keep them the right distance apart.

The manner of securing them from the side is different in the cope from what it was in the drag, it not being possible to place studs. Long chaplets are held loosely and drawn towards the outside until the cope is closed

FIG. 4—DRAG FOR HIGH PRESSURE " PISTON VALVE CYLINDER." NAILS DRIVEN INTO HEAVY BOSSES ARE TO PREVENT SHRINK HOLES FROM UNEVEN COOLING.

FIG. 6—CORE ROOM AND OVENS, SHOWING OVERHEAD CONVEYORS AND CHUTES FOR DELIVERING CORE SAND FROM SAND MIXER AT THE LEFT.

down for the last time, when they are shoved home against the core and securely wedged as shown. As will be readily understood, when the mold is clamped together, the cores are automatically clamped into place and no strapping down of chaplets is required as is common practice, but as an extra precaution wedges are driven from the outside between the cope and the top of the cores and in addition to this, staunch L shaped irons with toe on A, Fig. 7, are securely bolted to the flask, and resting upon the top of the bolt lugs of the main core arbor hold it firm. When the clamping and wedging is completed, vent rods are connected with vent holes in the different cores on the parting and project out through holes seen on outside of flask. After this the open spaces seen at Figs. 1, 2 and 3 are filled with molding sand, securely rammed in.

The manner of gating is also an interesting feature. Pop gates are used exclusively. These gates are made in cores and are about five-eighths by three inches and of sufficient length to saw off whatever length is required. They are placed on top of the steam chest flange and also on corner flanges on the opposite side. Good judgment must be used in placing them so that the iron will not strike any vital spot. To accomplish this they are arranged so that the iron drops into the bottom flanges. (Out of 150 cylinders made for I.M.B. engines and ranging in weight from 8 tons down to 3 tons not one has shown any sign of cutting from the iron falling this distance). The gates are connected on top by basin running the entire length of the mold and two 5-ton ladles are used in pouring. Abundant metal is flowed through the risers to insure against any possible kick from cores, doing harm and also to carry off any dirt which might have, through any means, been in the mold.

The mixing and melting of the iron is under the personal supervision of the foundry superintendent, Mr. James Gilson, and is the same as is used for the Gurney Fdy., Co.'s hot water boiler castings and is all pig iron bought only by analysis. The mixture found to be most suited to the work analyzes approximately silicon 2.40, sulphur .03, phosphorus .60, manganese .70. The resultant castings will be silicon 2.05 and sulphur .07.

Solvay coke is used as a rule but 72-hour coke is sometimes used. The secret being to use enough to have the metal properly melted.

When we consider that what is termed a steam cylinder, consists of, not only the cylinder itself, but includes the steam chest and valve seat with two sets of live steam ports, exhaust steam port with pipe opening and flange leading to next cylinder as well as the pipe opening and flange for live steam intake. Also bottom head of cylinder with all of its ribs and branches, small opening with flange to receive stuffing box, and to this add the bracket to which the columns are fastened, and the branches to which the lagging is attached, we may well say that to accomplish all of this without defect requires equipment and material of the highest order and mechanics who take second place to none. The name of "Gurney" is too well known in Canadian foundry circles to require further comment.

It was our privilege to see these cylinders machined and tested as well as inspected by Lloyd's Inspector at the Engineering Works of the John Inglis Co., where some of the engines are being built and we know whereof we speak. They were first-class castings.

ELECTRIC FURNACES

The Electric Furnace Co., Alliance, Ohio, have recently issued four bulletins descriptive of their various makes of electric furnaces. These furnaces work on the resistance principle, carbon resisters held in refractory troughs being used. The flexibility of this arrangement is such that the furnaces may be adapted to almost any use, and in sizes up to those big enough to take naval gun liners and jackets in vertical direction or ships' rudders in the horizontal.

The precision required in the production of all war materials, especially airplane, shell and gun work, has given the electric furnace a field of extreme usefulness, and one which promises to be capable of considerable development in peace-time industries. In this field the furnaces described are particularly useful, the accuracy of heat control being especially desirable. Hardening, quenching, and heat treatment are all done automatically. The melting of nonferrous alloys is treated of in two of the publications, and furnaces of large and small capacity are described, and data given as to their operation and efficiency.

The Independent Pneumatic Tool Company, of Chicago, have recently issued their circular, No. 28, which describes pneumatic and electric tools. Portable grinders, both of the electric and air operated types, are illustrated; drills are shown and floor and bench hammers for foundry work are illustrated and described at some length. The floor pneumatic hammer is shown in many of its newer developments. The circular is of interest at the present time in view of the activities being carried on in the shipbuilding industry.

FIG. 7—One half of core arbor for main core, showing curved iron enclosure for coke. The lugs marked A with bolt holes for fastening the two halves together, project through the core and are securely fastened to the flask, making the core perfectly secure.

Fundamentals of Beam Theory and Calculation

Action of a Beam Under Load—Bending Moment Explained—Simple Rules For Determining the Strength and Stiffness of Beams—Shear in a Beam

By D. A. HAMPSON, Assoc. Mem. A.S.M.E.

ON the subject of Strength of Materials, a "beam" is any part having one or more supports and acted upon by some force outside of the supports. If the force acted directly over the supports that portion of the beam would be subjected to tension or compression only and would be so considered mathematically—but when an overhanging part of the beam is loaded, the stresses set up must be calculated in a different manner. The "beam" may take various forms—it may be a steel beam for a crane runway, it may be the head block that takes the thrust in a straightening press, a bar of steel used overhead as a temporary fastening for a chain block, or the everyday wooden beam of carpentery.

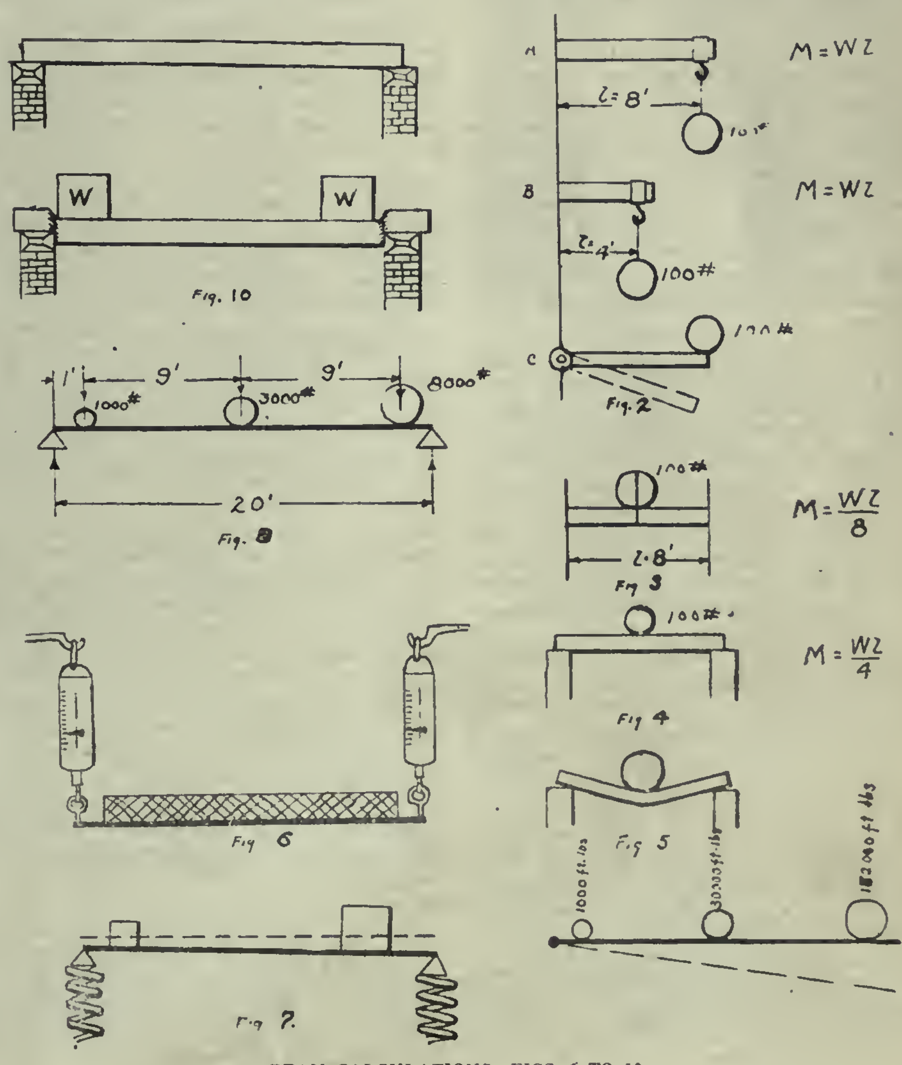
Fig. 1 is a typical beam, but one without any load. There is the load due to the weight of the material in the beam itself, but for short spans this is neglected; in many other calculations the weight of the material is not considered or, if it is, the designer adds an amount to the calculated sizes to cover this; in long and important spans this weight must be considered and to facilitate the work, those handbooks issued by steel companies rolling standard structural shapes give the properties of those shapes in terms that include the weight of the material without further calculation.

Unless acted upon by some external forces, the material of which the beam is composed is practically at rest, it having to resist no change of form except that due to its own weight. But when forces—which may be weights or other loads, pressures, or falling bodies—act upon the beam, it is stressed sometimes to the point where it breaks or is permanently deformed. Some shaped beams resist stresses better than others and the way a particular beam is turned makes a great difference in the resisting power, as for instance, an I beam is stronger resisting upright on the flat of one flange than it is if turned 90 degrees so it rests on the edge of both flanges. From the way a beam is turned and from its shape, the "section modulus" is calculated—this is the resisting value of the cross section and it, multiplied by the strength per square inch of the material, is the value used as one member of the beam equation—the "resistance member," it might be termed.

Nearly all beams will bend before they will break. The "bending moment" due to any load is the amount of that load multiplied by its distance from a support—a weight of 1000 lbs. placed 10 ft. from the support, creates a bending moment of 1000x10=10,000 ft.-lbs. In order that the beam be strong enough to stand up without breaking, the resistance member noted in the preceding paragraph must equal this bending moment and the calculation becomes that of solving an equation, one side of which is the resistance of the material in the beam section and the other side is the moment of the load on the beam. The unknown factor may be on either side of the equation. Also, both members of the equation must be in terms of the same denomination, that is, in either inch-pounds or foot-pounds (or inch-tons or foot-tons).

The moment of any force is its turning value about a point; in the case of a beam the point is the edge of the support. At C in fig. 2 is shown a cantilever beam which is hinged at the point of support to make the theory of bending moment more clear. With this hinged beam when the load is too great for the resistance of the joint to keep it up, the beam turns about the pivot and assumes the position of the dotted lines—the force exerted at the joint to make it give is found by multiplying the weight by its distance from the joint, and this value is the bending moment. If this bending moment were put in a beam equation the other member would be the frictional resistance of the joint instead of the resistance of so many square inches of metal of known strength which would be the value used in the case of an actual beam supported (not jointed).

But the same load does not always produce the same bending moment, as witness the cases of fig. 2, A and B, and figs. 3 and 4. All of these beams have a weight of 100 lbs. at a given distance



BEAM CALCULATIONS—FIGS. 1 TO 10

from the support. The maximum bending moment is denoted by M in all calculations. In fig. 2, A and B, the maximum bending moment is the product of the weight times the distance, but as the load is only half as far from its support at B as at A, the value of M will be only half as great in the former case and the same size of beam would be therefore twice as strong against bending. The beams A and B are cantilevers and, like all such have but a single support, so that they must be fastened, or "fixed" at that support to prevent tipping.

Fig. 3 shows a beam fixed at both ends and having a weight of 100 lbs. in the center. Though the load and length are the same as at A in fig. 2, the bending moment is only one-eighth as great. A little consideration will show that this is as it should be: if the beam and the load were divided by the vertical line we would have two cantilevers 4 ft. long with a 50 lb. weight at the ends and M for each would equal 4 x 50 = 200 ft.-lbs., but as actually the beam is not divided at this point, but is continuous, the value of M is even less, as proven by a solution of the formula, which shows M to be 100 ft.-lbs.

The beams heretofore considered have had their ends fixed; in practice, this may take a variety of forms, such as bolting or riveting to framework, set in masonry, or weighting. Other things being equal, the beam with fixed ends is stiffer and stronger than one not so fastened. A beam merely resting on supports is shown at fig. 4. The accompanying formula shows that it has a bending moment twice as great as the same beam with fixed ends—consequently it would bend under a load but half as great. Fig. 5 shows why this is so and what happens to an over-loaded beam that does not have the ends fastened.

Only a proportion of beams have loads such as just shown. Many have a number of loads, as the beam in fig. 3, others have a uniformly distributed load throughout their length, as the beam in fig. 4, while still others may have a combination of uniform loads and concentrated ones. All works on the mechanics of materials give the formula for M (the maximum bending moment) for various conditions of loading, figures 2, 3, and 4 being three of the most frequent conditions. Usually in designing a beam the length of the span is known, as is also the kind of support and the loads; the proper formula for finding M is then selected; the general shape of the beam is known and so is the strength of the material to be used from which is obtained the resisting moment, leaving the actual dimensions of the beam to be determined from the section modulus. As the resisting moment must equal the bending moment, these two are equated and the formula solved for the unknown term, which is the section modulus. Thus for the beam of fig. 3, of steel, rectangular with the long axis vertical, the processes would be—

$$M = \frac{W\,l}{8} \ \&\ M = S\frac{I}{c}$$

then

$$S\frac{I}{c} = \frac{W\,l}{8}$$

Substituting

$$60000\frac{I}{c} = \frac{100 \times 8}{8}$$

or

$$\frac{I}{c} = \frac{1}{600}$$

As the section modulus for a rectangular beam is

$$\frac{b\,d^2}{6}$$

the proportions of breadth and depth may be determined by trial from the value just found. For simplicity in the above, a factor of safety was left out and the breaking strength of the material used; in practice, the value 60,000 lbs. per sq. in. would have been divided by the factor of safety before using in the formula or else the factor would have been included in the formula, making it

$$M = \frac{S\,I}{f\,c}$$

Reactions are of great importance in beam calculations. Turning again to fig. 1, each of the piers supporting the beam bears a part of the weight of the beam and of any loads that may later be put upon the beam. If a single load be placed in the middle or several loads are placed symmetrically, or there is a uniform load throughout the entire length, each pier will bear one-half of the total load—in technical language, "the reactions will be equal."

It is not always clear to the beginner why this load on supports is called by the name of reactions. Referring to fig. 6, we have a beam that is suspended from spring balances instead of resting on supports. Assume for convenience that the beam itself has no weight. Then unless there is some load put on the beam, the pointer of the balance at each end will stand at 0. But when a uniform load is added throughout the length of the beam, each pointer drops an equal amount on its dial and indicates one-half of the entire load. This registered amount is the reaction—the springs within the balances are under tension due to the load and are resisting that load by pulling back (upward) as hard as they can, but they have been forced to stretch to the amount shown on the dial; but should the load be removed, the springs would immediately return the pointers upward to the original position.

Though loads may act in any direction it is customary in plotting them to arrange the drawing so they are acting downward. Then the reactions are upward. But in any case the reactions are opposite in direction to the loads which, in the average drawing, makes them to act upward.

It is very plain that a load on a beam exerts a force that has more or less tendency to bend the beam, but it is not so easy to conceive the reactions as a force. The experimental case of fig. 6 does show this; fig. 7 shows it in another way. Here, instead of solid supports under the beam, we have a compression spring under each end. Normally the springs are extended, but as weights are added the springs are compressed more or less, according to the amount and position of the weights. The reactions of the springs would be upward if the weights were removed just as would be the reactions of solid supports, though it would not be possible to see the latter "react" as it would be with the springs. When loaded, every beam creates a reacting force in the supports which would equal the amount registered on a dial of a spring of the form in figs. 6 and 7 could be substituted for the solid support.

The weight to the right in fig. 7 is larger than the one to the left and this compresses the right hand spring more than the other, hence the right hand reaction is greater than the other. Just what proportion is borne by each reaction could be told in every case by a direct reading on the dial of a spring balance, but this is not a practical construction, so a calculation is necessary for every-day work. The dash line in fig. 7 shows the position of the beam "unloaded" and shows graphically that the greater reaction is at the end bearing the larger load.

Fig. 8 is a typical case of a beam with three loads, where it is required to know the reactions at the supports, i.e., how much of the total load each support bears. The method of doing this is very much like that of finding the bending moment of a beam as described in a preceding paragraph. Either support may be selected as a center about which moments are taken. Take, for instance, the left support. Then the moment of the first load out on the beam is 1000x1=1000 ft.-lbs., of the second load 3000x10=30,000 ft.-lbs., of the third load 8,000x19=152,000 ft.-lbs. Adding these we get a total moment about the left support of 183,000 ft.-lbs. How this would act is made plainer by studying fig. 9, which shows the left support as a pivot and which has the right support entirely omitted; these loads would cause the beam to swing about the pivot as shown by the dash line.

The question is, "How much would it take at the extreme end of the beam (the point of action of the right reaction) to keep the beam up in a horizontal position?" This load of 183,000 ft.-lbs. is resisted by a support 20 ft. from the pivot, therefore it bears

$$\frac{183000}{20} = 9150 \text{ lbs.}$$

of the total load—and this is the amount of the right reaction.

The sum of both reactions must always equal the sum of the loads. So the left reaction may be found most easily by subtracting 9,150 lbs. from the total of 12,000 lbs., which gives 2,850 lbs. as the left reaction. This could also have been obtained by taking the right support as the pivot, or center of moments, and computing as before from that end. The result is the same in either case.

If the beam of fig. 8 had been supported on springs as the beam of fig. 7, it would have tipped at the right end just as the latter, showing that the greater load produces the greater reaction when so placed.

It is necessary to know the reactions in order to determine if the beam is strong enough against shearing. Fig. 10 shows a beam with a heavy load placed close to each support. Fig. 10 placed close to each support. The material of beam has not been strong enough and the loads and supports have become a veritable shears and cut the beam at two points. Such failures occur in machinery frequently; in structural work they occur as collapsing or crushing at the support, the conditions being such that this takes place instead of actual cutting off as with machine parts.

In more extended beam calculations, "shear" plays a prominent part and tells instantly a number of points which bear on the calculations. Shear is greatest at the point of support; however, though a beam would actually shear off only at this point, the numerical value of the shear is the same all the way from the support to the nearest load. If there were a single load in the center, the shear would be the same all the way out to that load —this is important for mathematical purposes; and it is interesting to note that at the exact center of the beam the shear is 0 while at this same point the bending moment is greatest.

LUBRICANT ECONOMY

By D. Street

One of the minor troubles in the mechanical business at the present moment, which is certain to become more acute as time advances, is that of lubrication. Oils, fats and greases, of whatever origin, do not increase and multiply. They grow scarcer and dearer. The troubles in this respect in enemy countries are their own, and it is certain that rolling stock of all kinds must be in a deplorable condition there owing to the blockade, and this matter alone is forcing the pace with regard to Rumania and Russia. Lubricants are as essential to the conduct of war and transport as food. With a shrinking tonnage available, importation must inevitably be restricted further still, and there is no natural supply of oil available in many countries. Tallow, lard, mineral oils, as well as those of vegetable origin, are all in like case. The shortage of edible fats has led to rationing these equably to the population, and practically the whole available supply of vegetable oils can be considered as withdrawn for food purposes in Great Britain.

Out of this shortage and scarcity arise several matters worth mention; the first of these exerts a natural check upon consumption; prices are rising steeply. The second matter is that relief in this particular cannot be expected; indeed, the conditions of scarcity will prevail after hostilities cease. Conservation of existing stocks therefore must be rigidly practised.

So far as possible all wastage should be avoided. In the normal shop quite half the expenditure upon lubricants is thrown away; every unit in the shop force should, as a point of honor, contrive to use as little oil as possible. For instance, the use of the oil can to drill a hole, or on any machining operation should be barred; it's up to the storekeeper to ration the supply with the strictest economy. The management should display in a conspicuous place warnings upon the matter, taking the percentage increase in cost and the need for rigid economy, of the national stocks.

Most moving mechanism can be efficiently lubricated with about half the considered normal amount. Where drip lubrication is in use a little careful investigation will show how to cut expenditure of lubrication. In deed and fact, without being parsimonious, and without grudging the needful supply, the drops per unit of time can in many instances be halved without danger of rise in temperature.

It was an experienced operating engineer who maintained from experiment that doing his own oiling round he cut oil bills 33 1-3 per cent. Bearings of common type, unprovided with drip trays, needing adjustment, and with surfaces in poor condition, require much more oil than those under the reverse conditions. To compensate and spin out the supply, and so save tonnage, every piece of greasy waste should be treated to recover the oil; a small centrifugal extractor and filter pays large dividends in a big works.

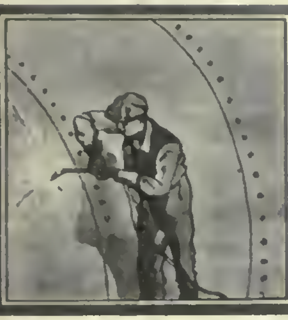
Care should be exercised over the oil can to see that this is in good shape and not leaky. One way in which the mechanical trades, and every man in association therewith, can help victory is to be sparing with the oil can. Owing to the fact that ball bearings need but one filling of grease, and this simply to exclude the grit, over a long period of time, the present high price of lubricants and the national need should instal these wherever possible.

A ball bearing will (dust excluded) run without lubricant at all, and present circumstances should make them more prominent than before. All grease and greasy material should be collected for treatment by refiners, and a large extension to ball bearing production should, to some extent, offset a peculiarly acute shortage.

UTILIZING SAW-MILL WASTES

Saw-mill waste amounts to about 40 per cent. of the original tree. The finished lumber, on the average, represents only from 30 to 35 per cent. of the tree. New developments in the utilization of wood waste are being made continually, but it is false economy to handle waste unless the by-product industries can be carried on at a profit. Effective utilization calls for a variety of chemical and mechanical processes which must be adapted to the form, species and quantity of wood waste available at any point. Slabs, edgings and trimmings represent 15 to 17 per cent. of the tree. Among the more common use are fuel, laths, box shooks, small slack cooperage, small wooden articles, kraft and sulphite pulp, excelsior, wood flour, wood wool and producer gas. Sawdust accounts for another 11 per cent., and is used to some extent for fuel, producer gas, briquettes, polishing metals, insulating, packing, bedding in stables, floor sweeping compounds, composition flooring blocks, linoleum, improving clay soils, smoking meat and fish, blasting powders, wood flour, plastics, porous bricks, mixing with mortar and concrete, distillation, ethyl alcohol, oxalic acid and carborundum. Bark amounts to about 10 per cent. of the tree. It is usually used for fuel, although hemlock and oak barks are important in the tanning industry. A recent development is the use of spent hemlock bark for mixing to the extent of about 30 per cent. with rag stock in the manufacture of roofing felts. Experiments on its use in wall board, indurated pails, conduits and wall paper give promise of success. In the manufacture of special wood products a good deal of wood is lost, during seasoning, by decay, due to poor methods of storage, and also by warping and splitting. There is a large waste in converting wood into the desired shape for the finished article. Proper co-ordination with plants making small wooden articles brings about a great economy of material. Shavings find use as a fuel and to some extent for packing, bedding, drying wet land and manufacturing fibre board. Beechwood shavings are required in large quantity by vinegar factories, but this is another case where specially cut wood is usually used instead of relying on by-product wood from various plants.

Steel founding is no child's play, the daily crop of problems raised and difficulties to be overcome being considerably more than encountered in most manufacturing enterprises. Steelmaking to-day cannot be undertaken by men without technical training. Notwithstanding the many alluring prospects presented by those who are anxious to sell and install foolproof steelmaking processes, there are none which may be so classified and which do not require closest attention of a practical metallurgist in order to produce high grade castings.



WELDING AND CUTTING

Returned Soldiers Make Very Good Welders

Training School For Welders Has Achieved 100 Per Cent. Success in Fitting the Soldier to Take up Peace-time Work Once More

By W. F. SUTHERLAND, Associate Editor

MECHANICAL industries of all kinds usually offer an attractive field for the returned soldier who is perhaps incapable of taking up his former employment. Many machine shop operations are closed to the injured man through their requiring considerable manual labor. These, too, in many cases, offer no opportunities for advancement and little chance of acquiring much technical skill. Autogenous welding is free from these disadvantages and offers the means of combining highly interesting work with excellent pay. In co-operation with the Department for the Soldiers' Civil Re-Establishment, L'air Liquide Societies have conducted for some time past a school for the re-education of the returned soldier in all branches of oxy-acetylene welding. The school has been an unqualified success. All men who have received instruction have made good, and are at present in positions demanding skill of a high order.

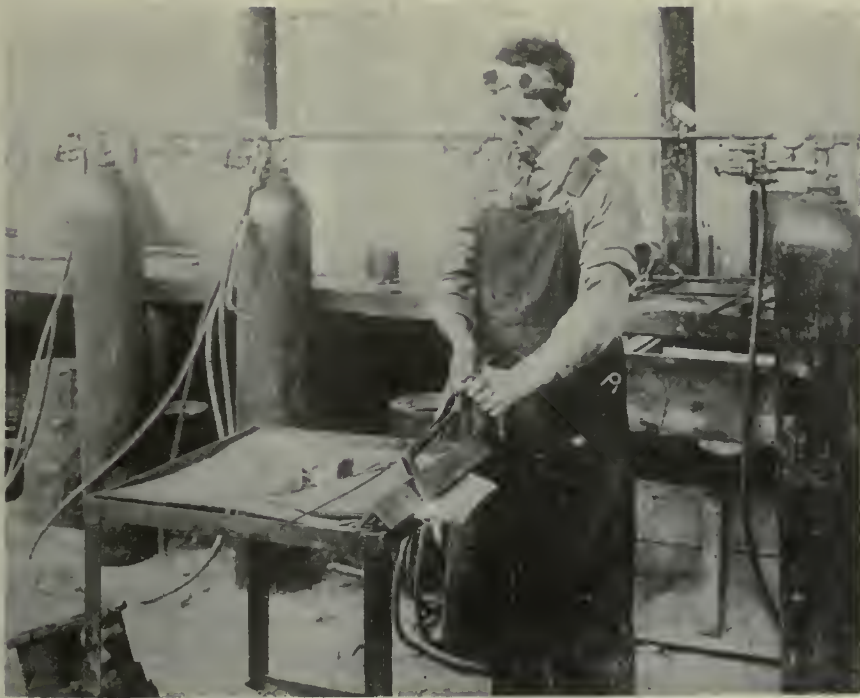
Although comparatively a recent development, the oxy-acetylene process of welding and cutting is a most important factor in modern industry, and its aid in promoting the enormous increase in the production of war materials and supplies incidental to the prosecution of the war can be scarcely overestimated.

Fifteen years ago the oxy-acetylene welding process was little more than a laboratory curiosity, but to-day it offers an exceedingly valuable opportunity for such returned men as wish to avail themselves of its advantages.

Duration of Course

After having undergone such medical treatment as might be necessary in the military hospitals, the soldier is given the option of choosing such instruction as he might desire to fit him for his life's work, guided, of course, by counsel and an appreciation of the disabilities which he may have. All courses are for a period of about six months or less, and are to a certain extent dependent upon

WELDING CAST-IRON AUTOMOBILE ENGINE CYLINDER—BUILDING UP BROKEN FLANGE



PRACTICING CUTTING ON STEEL PLATE

the skill and earnestness shown in acquiring knowledge.

On choosing the branch of re-educational work desired, the soldier is still under the direct jurisdiction of the department, being paid by them and his dependents cared for in like manner as was explained in a former issue.

vSraovkce4,aCjwofFCnoolatho ET ET

Instruction Given

The oxy-acetylene blow-pipe forms the first subject for instruction, its construction being gone into thoroughly, and an idea of the combustion of the gases used being given.

Correct welding practice is largely a matter of proper flame adjustment, the metal being either carbonized, correctly welded or oxidized as the flame is cargonizing, neutral or oxidizing in character. For this reason the characteristics of the different flames attainable receive careful attention, for to attain satisfactory results the pupil should be taught to distinguish the effect of correct and incorrect adjustments of the flame by its appearance and by the appearance of the molten metal.

The welding of steel is first taken up, the pupil being given instruction in the use of the cutting torch at the same time. Pieces of thin sheet steel are cut by the torch and then welded together. But joints are first welded, the more difficult lap being attempted as skill is attained. It might be thought that the welding of pieces of moderate thickness would be easier to start with, but it has been found that the welding of thinner work gives more scope for instruction and presents greater opportunities for the acquiring of skill.

Cast Iron Welding

After having done sufficient of the steel welding the pupil is put on cast iron work, as before scrap pieces being first employed for the acquiring of skill. As soon as advisable the repair of cast iron objects, deliberately broken, is attempted, automobile cylinders and other objects being cracked and then repaired. The building up of broken parts is done replacing parts broken off castings.

Almost every class of work is done, scrap material of every kind being used. This gives the pupil a wide field in which to gain experience. One example of work is to be seen in a flywheel with cracked arms and rim, the welds have been made, not by one man alone, but by a number, so well that little refinishing is required.

From the welding of cast iron the pupil goes on to the more difficult work of welding brass and aluminum, actual work being done on commercial articles.

The class of work being done by those who have received their instruction is well illustrated in the plant of L'Air Liquide Societe itself, the most complicated and difficult work being done by those who have received their instruction in the school.

Throughout the course the importance of pre-heating and allowance for expansion and contraction are not lost sight of.

Welding may be said to be an acquired art, and much depends upon the excellence of the instruction received and the sympathetic and interested attitude of those responsible. The school for instruction is carried on under the direct supervision of Mr. MacDougal. Altogether 20 to 30 men have received instruction as many as nine receiving instruction at one time.

ELECTRIC WELDING APPARATUS

Electric welding apparatus of extreme simplicity and of great adaptability has recently been developed by the Arcwell Corporation of Canada, 710 C.P.R. Bldg., Toronto. This apparatus, by its use of alternating current, does away with the motor-generator sets and other apparatus hitherto employed for this purpose, and by the accurate control and characteristics of the flame effects a remarkably successful joint.

The design of the apparatus resembles that of a transformer and is fitted with a number of taps, also electrode - cable with holder. Machines are built for any of the various commercial voltages and frequencies being stepped down through the medium of the transformer to the welding voltage of 20 volts. In operation the welder takes 3¼ to 4 K.W. energy, which is equivalent to about 5 h.p.

Taps are provided on the secondary or low voltage side for various amperes, and the flame produced is extremely hot and is all concentrated in the small arc. The character of the flame and the weld produced eliminate all trouble due to crystallization by heat of the metal being worked upon.

CHIPPING PLATE AFTER CUTTING FOR WELDING

The Mephisto arc welder has been used with excellent results on ship and boiler plate and steel castings of every description with no deterioration of the metal worked upon, and it has been demonstrated that the equipment has a wide range of ability to achieve results equal in character and quality of weld to that obtained by other systems, either electric or oxy-weld, at a very much lower cost, and in much less time.

The manufacturers draw attention to the fact that the arc is very stable and in consequence it does not by any means take an expert to handle it, any workman of average intelligence becoming accustomed to its use in a very short time. This fact, coupled with the much cheaper cost of electrical energy as compared to the other welding mediums, lowers production costs from six and eight dollars a day down to about one dollar per day.

ELECTRIC WELDING APPARATUS OF NEW DESIGN

An extremely favorable characteristic of the weld produced, is the ease by which it can be machined and finished, no difference between the weld and the body of the metal being apparent, and an ordinary file readily takes hold.

On account of the portability of the apparatus its usefulness is wide and it has already filled an important place in the shipyards, foundries, and machine shops of the United States.

While the standard equipment has a rating of 150-amperes, larger capacity machines are furnished, but where heavy work is to be done, the use of two or more 150-ampere units in multiple, is recommended, this arrangement having the additional advantage of flexibility.

The equipment is of very rugged construction, housed in a substantial wooden box, strongly braced, and is self-cooled throughout. Any type of metallic electrode, plain or coated, or carbon electrode can be used.

AN AUTOMATIC ENCLOSED GASOLINE ENGINE

By FRANK C. PERKINS

The automatic four cylinder enclosed gasoline engine noted in the accompanying illustration was developed at Bridgeport, Connecticut, U.S.A. This four cycle marine motor is said to have maximum economy of fuel and upkeep. It has a bed consisting of a substantial one-piece iron casting, the lower half being octagonal in shape, cast integral with base and with large oil reservoir located in center. There are flanges on either side for bolting to the frame work, and a square groove through center of base for crank shaft bearings. The sub-base is fully enclosed and securely bolted to the bed, on top of which are mounted the cylinders, magneto and governor assembly. In the side of the sub-base are hand holes for ready access to make adjustments on connecting rod and crank shaft bearings, while the cam shaft is also located in sub-base.

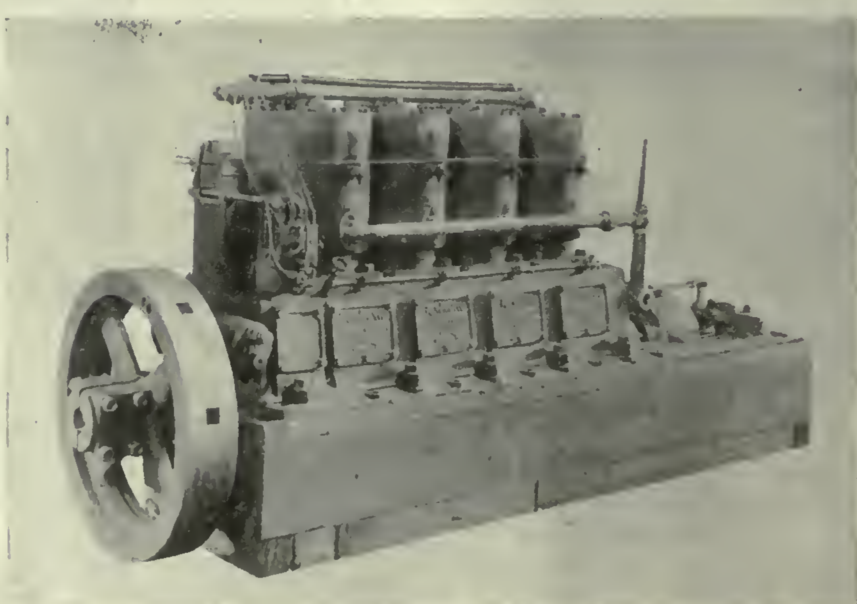
The square groove in the bed receives the crank shaft bearings and upper half of the gearing is reinforced by a steel plate onto which the cap adjusting screw rests. The bearing adjustment is made by turning an extra large octagonal head screw with keeper. This method permits adjustment without loosening the cap, which is thoroughly and permanently fastened in position. The keeper prevents this screw from working in either direction, and makes a quick and efficient adjustment.

The balance wheel is made with a split hub, bolted to crank shaft with four large bolts; also fastened with a large square key, insuring a perfect fit with no side motion or wobbling. Because of this split hub the balance wheel is easily taken off when necessary to do so. The crank shafts are hammered from solid blanks of high-carbon steel and one cam shaft only is used, of 40 carbon machinery steel and on the shaft are cams for operating inlet and exhaust valves. The solid bearings for this shaft are of cast iron with bronze bushing.

The cylinders are of L type, one-piece castings, having separate heads. The top face of cylinder is without cored holes, except one for circulating water, and this is outside, so that there is no possibility of water entering the cylinder. The cylinder heads are cast of the same iron as cylinders, with ample water space around valve hole covers. In coring the cylinder heads there is no opening whatever between the head and cylinder, except at the extension for water provided to meet extension in cylinder. The water circulation is of special interest. Extra large water space has been allowed in the cylinders, cylinder heads and around valve seats, the water being supplied by a plunger type of pump attached to the aft end of each engine and operated by an eccentric on the cam shaft.

The valves are of nickel steel, the end of the stem being threaded and provided with special clasping locknut for adjustment. The valves are so situated that they may be reground and seated without removing cylinder head. The valve head caps are of cast iron with air-cooled vanes to assist cooling spark plugs. The valve lifters are of the mushroom-head type, slightly off center of cams, and made of open-hearth steel, fitted into separate cast bushings and held securely to the sub-base. This type of lifter allows a great area of opening for a long time, which is most desirable.

The lubrication is provided by a large geared force pump, connected to the spacious reservoir in bed of motor. The question of oiling an engine thoroughly has been taken care of. The oil pump is located inside forward end of engine,



BACK VIEW.

Electrical Engineers Meet in Toronto

Interesting Canadian Developments in Electrical Engineering Described at Meeting Held Under the Auspices of the Toronto Section of the American Institute of Electrical Engineers

THE development of Canada's waterpowers, the features of design being developed for transmitting electric energy, and the electrification of her railways, formed the interesting subjects of papers read before the 344th meeting of the American Institute of Electrical Engineers, held in Toronto, Friday and Saturday, Nov. 22-23. This meeting has a special interest for the engineering profession of Toronto, in that it is the first meeting of the main society ever held here under the auspices of the local section.

Members were present from various points, New York, Philadelphia, Niagara Falls, Erie, Pittsfield, Pt. Huron, Schenectady, and other points including Austin, Texas.

The afternoon session, Friday, was opened by the chairman, Arthur H. Hull, who, in his address, welcomed the American delegates. F. L. Hutchison, the secretary of the A.I.E.E., in the absence of the president through war activities, responded. The Toronto section was one of the first local sections organized. The plan of establishing local sections was first brought forward in 1902, and this section was organized in 1903. It is one of the few that has kept up its activities during the war to anything approaching pre-war standards.

In a paper read by Arthur H. Hull on "Electric power generation in Ontario on systems of hydro-electric power commission," the progress to date of the municipally-owned system was outlined.

Ontario has developed into the greatest manufacturing province in Canada, and as there are no coal deposits its abundant waterpower resources are being more and more utilized to furnish the power required for its varied industrial developments. About 702,000 horsepower are developed in Ontario at present, leaving a total of 4,227,000 horsepower still available. Of the above total for power developed, about 69,000 horsepower is used in pulp and paper manufacture, about 59,000 horsepower is used as hydraulic power directly applied, and teh balance, 574,000 horsepower, is converted into electric energy for light and power. The commission now own and operate ten systems in the various parts of the province from Port Arthur to the Rideau and St. Lawrence, and as far north as Nipissing Village. The various systems were described in detail and data given on the new Queenston development now under way, as well as on the extensions now being carried on at the Ontario Power Company plant. In connection with this latter, the speaker stated that the two new generators of 15,000 kva. rating each, were made in Canada, with the exception of the steel laminations and insulation. This speaks well for Canadian industry under war conditions.

The second paper read on Friday afternoon by Mr. W. G. Gordon on the "Electrical equipment of the Canadian Northern Tunnel in Montreal." This work is one of the most important that has been undertaken in Canada of recent years, and the features of electrical design dealt with in the course of the paper were of unusual interest. Following a description of the tunnel proper and the terminal conditions which had to be dealt with, the author entered into a detailed description of the electrified portion of the track ten miles in length. It is later proposed to extend this electrification of the railway to Ottawa, and the substation feeding the system was located with this fact in mind. Power is obtained from the Montreal Light, Heat and Power Co. at 11,000 volts and 60 cycles, and by means of motor generator sets, is distributed to the railway feeders at 2,400 volts direct current. This voltage is the highest that has been used in Canada up to the present time for this work, and was chosen in view of the contemplated extension of the system.

Three types of traffic had to be considered in planning the equipment: passenger and freight trains and suburban traffic. The suburban traffic will be handled by multiple unit trains, each coach weighing 80 tons, and being patterned after the standard vestibule passenger coach. The passenger and freight traffic is handled by six locomotives; these locomotives are of the two four-wheel truck type, the two trucks being coupled together to the draft gear, leaving the body of the locomotive free from all stresses.

Pantograph collectors are used with overhead catenary suspension of the trolley wires.

Sir Robert Falconer

At the conclusion of the discussion on the above paper the members and delegates adjourned for dinner. Sir Robert Falconer spoke on the impressions he had gained on the occasion of his last visit to the western front a short time ago.

The bravery and fighting qualities of the Canadian Army Corps were never more in evidence than at the battle of Amiens, and later at Arras. Vimy Ridge was a glorious episode, and one in which the Canadians won lasting fame, but the two latter battles in the speaker's opinion were even more to their credit. Sir Robert had the good fortune to be present during the opening stages of the battle of Arras, and the sight of the Canadian reserve divisions pouring up to take their part in the struggle was one never to be forgotten; the columns of men, artillery and transport, moving on with clock-like regularity, and proving irresistible in battle to the foe.

The German troops opposite Arras got the surprise of their lives when they found the Canadians were the ones who were putting them to rout and bagging them as prisoners. It seems that these selfsame prisoners had been moved to the quiet Arras sector to rest up a bit after the terrific mauling they had received at Amiens a few days before at the hands of the Canadians.

One of the most important lessons the war could teach the people of the allied countries was the value of research and science in either war or peace. Organization was always one of Germany's strong points, and it was well known that the United States was her equal, but Great Britain was thought to be woefully backward in this particular. However, her organizing powers were not dead but merely quiescent.

Science, while adding horrors to the war as conducted by Germany, yet had achieved one of the miracles of the age in the success which had attended the efforts of the medical staff of the armies in the field. Preventive medicine and surgery had made greater strides in the last few years than ten years of peace would have brought about.

Engineering at the front was, in the last analysis, one of the material factors in the bringing of victory to the allied standard.

Long Span Transmission Lines

The evening session, held in the Chemistry and Mining Building, University of Toronto, was devoted to a paper read by Mr. S. Svenningson on the longest span river crossing yet erected. The paper dealt with some remarkable contruction work recently completed by the Shawinigan Water and Power Co. near Three Rivers, Que. The St. Lawrence River is crossed by transmission line wires on a span of 4,800 feet. Due to the necessity of maintaining navigation clearance, the towers are 350 feet high.

Four reinforced concrete cassions, 11 feet diameter for each tower, have been sunk to a depth of 45 feet and placed on the corners of a 60 ft. square. These piers are connected by heavily reinforced concrete beams 4 ft. wide by 8 ft. deep. There are two towers 350 ft. high, and 60 ft. square at the base, the upstream and downstream faces tapering to a width of 14 ft. at the top. The cross arm at the top is 14 ft. wide by 100 ft. long, and carries the three sheaves over which the main steel messenger cables pass to the anchor towers.

Three lines of cable 50 ft. apart span the river between the two towers. The cables are 1⅜ in. in diameter, and are made of galvanized plough steel. They are composed of six strands of 19 wires each and a stranded core of 30 wires. To each end of the center span cables is yoked two anchor span cables; these are carried over the tower on the 8 ft. diameter sheaves and then down to a point about 20 ft. from the anchors. At this point equalizing beams are cut in the lines, and the load is transmitted from this point to the anchor piers by means of short straps of 1¾ in. cable.

It was originally intended to use the main cables as conductors and to insulate them from the tower by specially-designed insulators. Unfortunately these insulators were not completed in time for erection and the main cables are now used as messengers carrying a No. 1/0 stranded copper conductor on suspension insulators.

Visit Local Plants

Saturday morning the delegates and local members visited the British Forgings, Leaside Munitions, and the Strachan Ave. terminal station of the Ontario Hydro Electric Power Commission and their laboratories on the same site. Canada's share in the supplying of munitions to the Allies and to the United States is due in no small measure to the enormous output of the British Forgings and Leaside Munitions plants, and the opportunity of visiting the world's largest electric steel plant was one which the majority of the delegates availed themselves.

Japanese Government Aids Engineering Industries

Is Keenly Alive to Possibility of Making Japan's Chemical and Steel Industries Self-supporting — Representatives Getting in Touch With Latest Developments in America and Europe

THE world-wide shortage of raw materials and the dislocation of trade consequent upon the war has been felt fully as much in Japan as elsewhere. The iron and steel industry and those manufactures depending upon chemical science for their existence have suffered most of all in Japan. To meet these conditions and to make the country self-supporting to a greater extent, the government is taking active steps to establish permanent industries in Japan, and in doing this is investigating recent progress in other countries.

Two government representatives have been in the United States for some time looking into the various phases of manufacturing as there carried on, and last week availed themselves of the opportunity of inspecting some of Canada's progress in the steel industry. Mr. Shin Nakahara, Mr. S. Sakai and Mr. Genjiro Jinguji, consulting engineer of New York, were in Toronto at the meeting of the American Institute of Electrical Engineers, held under the auspices of the Toronto section, and while here were very much interested in the operation of the British Forgings electric steel plant.

Mr. S. Sakai, chemical engineer for the Imperial Industrial Laboratory, Osaka, Japan, and Mr. Shin Nakahara, of the Imperial Steel works, Yawata-Shi, Japan, are both graduates of Japanese universities, while Mr. Genjiro Jenguji, who is representing them, and whose offices are at 15-21 Park Row, New York, is a graduate in engineering of the University of Illinois.

In conversation with a representative of CANADIAN MACHINERY, Mr. Shin Nakahara stated that the electric furnace in the steel industry was extremely interesting from the Japanese point of view, and offered opportunities for the production of high-grade and alloy steels of which they were going to avail themselves. The Imperial Steel Works have at present a 5-ton furnace and expect to increase their capacity in the near future. Questions of electrode and current consumption, life of furnace linings, control, and quality of steel produced were all of the greatest interest to him, and much interest was evident in the arrangement and operation of our National Electric steel plant. The scope of the work contemplated may be appreciated in his statement that he was desirous of getting in touch with makers of equipment for blast furnace, open hearth and bessemer plants and electric furnace plants, including all electric equipment. Rolling mill installations were also contemplated, and it was expected that plates, sections, and bar steel would be rolled.

The iron and steel industry offered excellent opportunities for expansion, and the vast potentialities of China as a source of raw material and as a market for finished wares would in time prove of immense value in establishing a permanent market.

Chemical Industries

Japanese textiles, needless to say, are noted the world over, and German dyes have for many years played an important part in their production. This trade has been probably lost to Germany for ever, if contemplated developments in Japan mature. Coal tar dyes, while important in themselves, are only a fraction of the immense number of substances produced through the medium of chemistry of the carbon compounds, and the development of the iron and steel industry necessitating vast quantities of coke, goes hand in hand with chemical enterprises.

Energetic means are being taken to make Japan's chemical industries self supporting. and the building up of her industrial life demands the entering into nearly every branch of it, so closely are they interconnected.

A few of the items which it is proposed to manufacture necessitate the purchase of equipment for the making of acids, dyes, caustic manufacture. and for electro-chemical industries. These latter include electric furnace equipment for iron and steel, carbide, cyanamide, and ferro-alloy manufacture, together with electrolytic equipment for theh refining of metals, plating, etc.

Laboratory supplies are also badly needed, optical goods, glassware, furnaces, and practically everything which is found in the usual industrial laboratory are badly needed.

Opportunities for the building up of an export trade in the lines indicated are very promising according to the statements made by the representatives, and in many lines the possibility of building up a permanent business in some of the lines is apparent. The manufactures required may be roughly grouped into two main divisions, chemical industries and the iron and steel industry.

The Japanese steel industry requires blast furnace plants, open hearth and bessemer plants, electric furnaces and equipment, and bar shape and plate mills.

Chemical laboratory supplies may be summarized as follows: Optical goods. pyrometers, microscopes, polarimeters, ultra microscopes, stereoscopes, etc.; chemical glassware and general laboratory apparatus; muffle furnaces, combustion trains for carbon determination, chemical balances and other general analytical and research apparatus.

In the field of industrial chemistry the possibilities for export trade are wide. The dye industry. acid and alkali works, carbide. cyanamide. and ferro-alloy are industries offering an opportunity as extensive as it is varied.

A NEW PLANER FOR SHIPBUILDING PLANTS

A new industry just established in Montreal is the manufacture of the simplex electric planer by the Simplex Floor Finishing Appliance Company. It is claimed that one of these planers does the work ordinarily done by twenty men in hand planing. It is used extensively in shipbuilding. Eight of them varying in length from 150 feet to 300 feet have been supplied to the Canadian Vickers Company. It is stated that these planers can be reset in a few minutes from planing rough timber to polishing deck surfaces or ways in shipyards.

Grinding; Its Utility in the Modern Shop

Grinding Has Become an Operation of Great Utility and Successfully Replaces the Lathe in Many Lines of Manufacture

By D. STREET

DESPITE the recent great extension of grinding as a machine shop operation erroneous ideas as to the sphere of action of the grinding machine and as to the principles and practice of the grinding processes are still prevalent. It is still widely believed that grinding is only necessary or advantageous when hardened work has to be dealt with, that it is essentially a slow process, that its scope does not extend much beyond the giving of a final polish to an already rough tooled surface, and that any way it is not of much use for general work, as distinct repetition manufacture. These ideas, among others, were effectively dealt with by Mr. H. H. Ashbridge in an excellent paper on "Workshop Precision Grinding," read before the Manchester Association of Engineers recently. At bottom they are founded on a belief that grinding is in essence a rubbing or polishing process. That, of course, is incorrect. Whether the materials to be ground are in hardened or soft state, or whether forged or cast, grinding is just as surely a cutting operation as using a lathe or planer tool. Just as the tool has one cutting edge, and will remove a chip proportional to its strength, so the grinding wheel has multiple cutting edges and the chips removed by each cutting edge bear a striking resemblance, when examined under microscope, to those produced by the lathe tool. It is not claimed for the grinding wheel that it can compete with the lathe or other machine tools as a metal removing machine, as measured by bulk of metal removed, but in any metal-removing operations that include finishing, a point is reached when the grinding machine in some form or other will remove metal faster than the cutting tool of the machine. No universal rule can be given for readily determining the point at which the advantage passes from tooling to grinding; it must be judged from each piece of work separately. Some typical examples are, however, on record. In the course of tests carried out by Mr. Dempster Smith at the Manchester School of Technology, it was found for example that the best attainable time for a finishing cut of 0.003 inches, with a lathe on an 8-inch shaft, was 7¼ minutes per foot, while a grinding machine would remove the same cut in 1½ minutes per foot. These times are for grinding and tooling to approximate size. For the whole work of removing the same cut, and also sizing to within .005 inch limits the grinding machine would require only four minutes; what the lathe would require over and above 7¼ minutes for sizing, filing, and polishing is not stated. Experience goes to show that the last thin skin of metal up to .015-in., .02-in. thick can be removed quicker in the grinding machine than any other method of machining, while if the amount of metal left on for machining is not very great, the grinder can do the whole job, roughing and finishing, very much quicker than the lathe. From an 8-in. shaft a cut of 1-32-in. can be removed by grinding at the rate of four or five minutes per foot length. Against the common belief that the grinding machine is one used for mixed work the grinding machine shows to advantage on repetition work, owing to its arrangement for accurate feed and automatic trip when the article being ground has been reduced to its predetermined size; these same features also make the machine advantageous on single articles, as after taking a few trial cuts, the work is measured for the amount oversize, and the micrometer feed set to take off the remainder, which can be done with great exactness. One important point rightly emphasized is that while the operator may by skill counteract the faults of a defective lathe, the grinding operator has no such recourse; hence grinding machines must be correctly designed well made and properly maintained. Moreover, the lathe operator can get moderately good results within wide range of speeds, feeds, and tool shapes, but in grinding the conditions of efficiency are much more narrowly circumscribed, and the operator must follow closely the directions, or the result will be not merely diminished efficiency but failure. The qualities essential to good grinding machines are truth and rigidity. The necessity for a high degree of truth will be seen from a moment's consideration of the fact that, while most machining operations are of a primary character, the ultimate finishing being done by other means, such as the file or a scraper, a grinding machine or a finishing machine, in which the work produced needs no further correction. For this reason, it follows that the sliding surfaces of the grinding machine should be as nearly as possible true planes, otherwise accuracy of product is impossible, and the object in view isolated. The limits of error allowed in building grinding machines are "none," but certainly the highest degree of accuracy is essential. Rigidity is no less important, and especially rigidity in the grinding wheel head, which must be heavy enough to carry the largest and the broadest wheel with which the machine may possibly be fitted, and also to overcome any possible want of balance in the wheel itself, while the spindles and its bearings should be of similarly ample proportions. It is for this reason that the grinding machine cannot very well be improvised. Many attempts have been made to convert the lathe into a grinding machine by means of attachments, but such attempts can only meet with very moderate results, owing to the lack of the necessary rigidity. Yet another essential quality in a grinding machine is ample driving power, in order that the whole may not slow down during momentary heavy cutting. Not only is the wheel wasted by being allowed to slow down, but what is more important, the wheel face is destroyed, and more frequent truing up is necessary. Many a potential user of the grinding machine has been put off by the thought of the number of fairly expensive grinding wheels of various widths and grades that must be kept on hand for the different kinds of work. For plain external grinding it is very unusual in general machine work to require more than two wheels to a machine, one to grind all classes of steel work with, and the other to deal with all cast metals. Closer grading can be done where the work is all of one class, but for general mixed work a couple of wheels can be arranged to efficiently cover the range. This has only been made possible by quite recent improvements in wheel manufacture. Perhaps the most striking item is concerned with wheel width and table travel. The two must be considered in conjunction. It is of very little use to have a wide wheel in combination with a slow table traverse. The only result of such a precedure would be a limitation of the production of the machine, and excessive wear on the portion of the wheel used, causing the machine to generate a round face, and making frequent truings necessary in order to cut away the unused portion of the wheel. The question is often raised whether the wheel keeps flat when grinding work with shoulders. If the traverse of the work per revolution is less than half the width of the wheel, then the cutting face of the latter will gradually wear convex, but if the traversemper revolution of the work is over half the width of the wheel, then the wheel will preserve a flat face. The ideal traverse per revolution of the work is about two-thirds the width of the wheel, but it should not, except for finishing, be less than half the width. It is for this reason that the grinding machines are now being built with table speeds of 16 feet per minute over, in combination with wide grinding wheels. The main factor governing production on external cylindrical machines is the combination of wide wheels with fast table speeds, as, other things being equal, the machine which possesses these advantages is the most efficient tool. Work speed is the least important of all the factors mentioned.

WHAT OUR READERS THINK AND DO

Views and Opinions Regarding Industrial Developments, Factory Administration and Allied Topics Relating to Engineering Activity

HOME-MADE TOOLS FOR THE ELECTRICAL REPAIR MAN

BY MAURICE CLEMENT

It is surprising to note the large number of homemade tools one can see in an electrical repair shop; the fact that none of these tools can be bought ready-made, but must all be specially constructed, gives them an interest that is lacking in all standard tools; everything from a coil taping needle to an armature banding tension block, can be seen among an armature winder's tools.

For the benefit of those who are interested, I shall go into detail concerning these tools. The first, and most simple, is the "coil taping needle." This is made of a length of No. 14 banding wire, as shown in Fig. I. As only one foot of the wire is used in making the taping needle, it can be had at a very low cost; the taping needle is used for taping coils in closed slot stators, and when the user becomes accustomed to it, much speed can be attained, thereby saving considerable time.

The coil raiser, also in Fig. 1, is simply a piece of steel, 16 inches long, 1 inch wide, and 3-16 inch thick, with a 4-inch one-sided taper to it on one end. This tool is used mainly in stripping open slot armatures and stators, but can also be used to good advantage in removing grounded coils sufficiently to allow for insulating a weak spot in the coil, the main object being, in this case, to lift out a tight fitting coil without damaging the insulation.

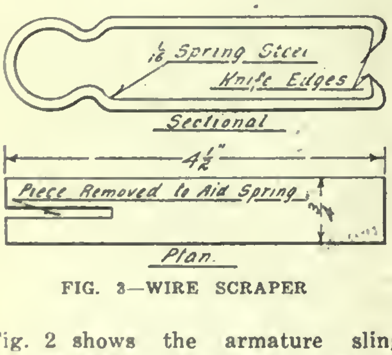


FIG. 3—WIRE SCRAPER

Fig. 2 shows the armature sling, which is made of a piece of 1-16 inch sheet iron, 2 feet long and 10 inches wide; at each end is a steel triangle, made of a ¾-inch steel bar, for hooking on to a crane. Without this sling, a rope or wire cable strap would be used, with the danger of springing the shaft; in a recent test this sling has held a

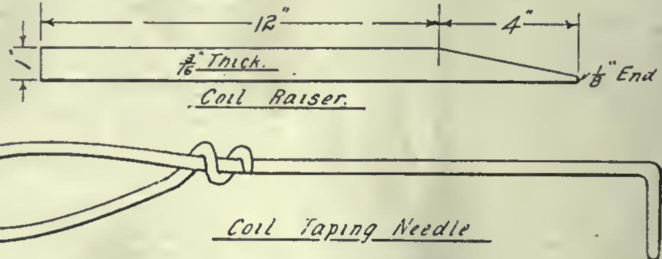

FIG. 1—COIL TAPING NEEDLE

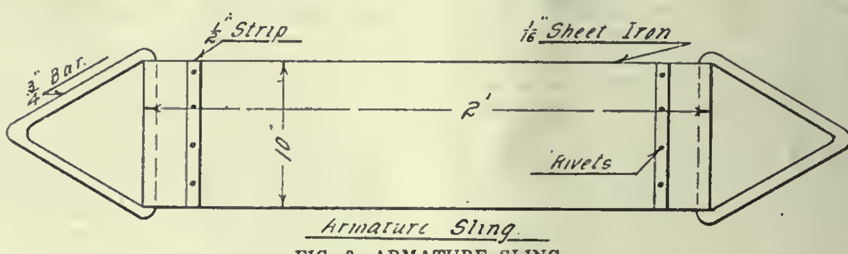

FIG. 2—ARMATURE SLING

weight of one ton, without apparent strain.

The wedge-drift is a piece of tool steel 8 inches long, ⅝ inch wide, and 3-32 inch thick; over which is fitted a loose fitting steel sleeve, 1-16 inch thick The wedge-drift is used for driving fibre wedges between top of coil and lamination overhang in closed slot machines; to use the wedge-drift most efficiently, the fibre wedge must first be inserted about a quarter-inch into the slot, then with the drift pulled back in the sleeve, fit the sleeve over the wedge and drive to the proper place; the sleeve holding the wedge in its position properly and preventing breakage.

The wire scraper, Fig. 3, is one of the best little time-savers of the whole lise. In ordinary circumstances a knife is used to scrape wires prior to connecting, but with the rough treatment a knife receives in scraping wires, its life is very short, necessitating frequent renewal of knives and incidentally, added

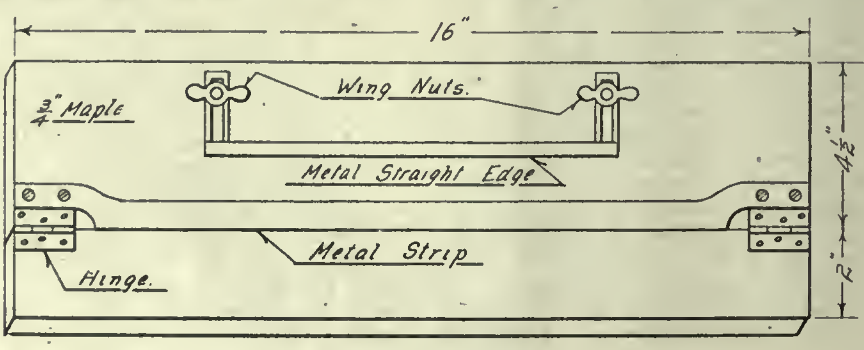

FIG. 4—CELL SHAPER

expense. The wire scraper is made of spring steel and is primarily 1 foot long and ¾ inch wide; before bending to the desired shape, grind a knife edge on each end and cut out a piece 2 inches by ¼ inch from the centre.

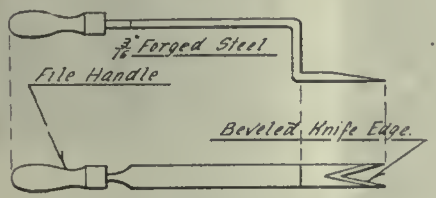

FIG. 5—CELL CUTTER.

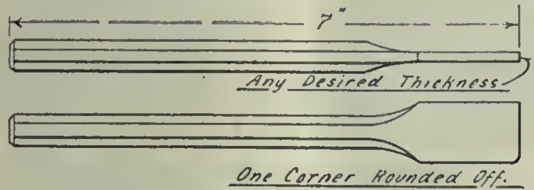

FIG. 6—DRIVING DOWN TOOL

After bending to proper shape, knife edges can be retouched with a file. The open space, which is now at back end of scraper, gives a greater spring effect and allows knife edges to be brought together with a minimum of pressure. In Fig. 4 we have the cell shaper, which, when we take into consideration the valuable work it does, is well nigh indispensable to any well regulated repair shop; the base of the cell shaper is of hard wood, in this sase being maple; it is composed of two pieces, one being 16 in. x 4½ x ¾ in., the other is 16 in., x 2 in. x ¾ in. These pieces are hinged together on the long edge.

Where the two pieces of wood meet, a half-inch metal strip is piaced. This strip is shaped at the ends so as not to interfere with the action of the hinges, and held down by screws; between the hinges the strip is raised sufficiently to allow the inserting of a reasonable thickness of fish-paper.

Behind the metal strip is an adjustable metal straight edge with wing nuts to hold it in place; to make a cell for a closed slot stator or armature, length of slot must first be determined, allowing for a short projection. Next, height of slot, measuring from bottom of slot to bottom of lamnation overhang; width of slot at the bottom must also be determined. This gives us the following:—

Length of slot + projection = one dimension.

Height of slot x 2 + width at bottom = other dimension.

In cutting the fish-paper for these cells, it must be remembered that there is a proper and improper way of doing it; the grain of the paper must be taken into consideration. The right way to cut it is to lay out the first dimension with the grain and the second across the grain. In adjusting the cell shaper, the distance from the forward edge of metal strip to the metal straight edge should be equal to the height of slot.

To shape cells, insert fish-paper under metal strip until it is squarely against straight edge and turn hinged base on hinges; this will make a neat fold in the paper; turn paper around and make another fold on opposite side, all is now ready to use.

In Fig. 5, the cell cutter is another very simple, but very effective tool. It is composed of a piece of forged steel, 14 inches long, ¾ inch wide and 3-16 inch thick, with a set of bevelled knife edges at one end and a file handle at the other; the handle is raised so as to allow free movement of the cutting end. It is used in cutting projecting insulation from slots of open slot windings after coils have been assembled.

In Fig. 6 we have the driving down tool, which is nothing more than a thin bladed chisel, with the end squared off. It is used for driving down leads into commutator slots. It is advisable to have four or five chisels with various blade thicknesses, to provide for different sizes of wire. The armature banding tension block, shown in Fig. 7, is a device which does away entirely with the necessity of a banding lathe; in the small shop, where the armature winder does his own banding, the tension block is an innovation worthy of notice; the armature does not have to be removed from the stand to be banded.

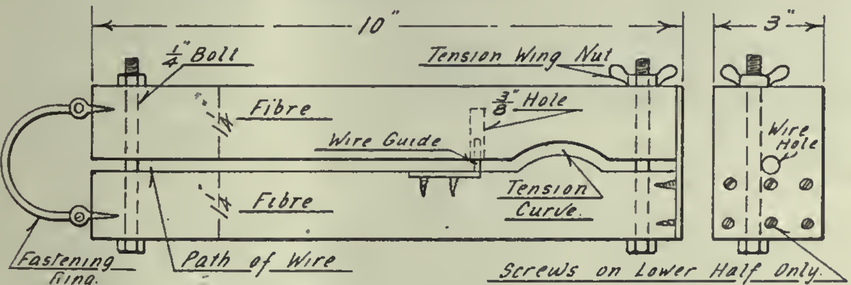

FIG. 7—ARMATURE BANDING TENSION BLOCK

About one foot of stout line with a hook lashed to one bed is made fast to the fastening ring on the tension block and hooked to an eye bolt, which is set in the floor for that purpose. The spool of banding wire is placed on a small stand beside the eyebolt; the wire passed between the two blocks at the rear end, through hole in first wire guide over tension curve, and through second wire guide hole, thence to the armature.

The tension can be regulated by the wing nut at the forward upper end of the block; by screwing down the wing nut, both sides of the block are brought nearer together, thereby narrowing the tension curve over which the wire must pass, this increases the resistance on the wire and incidentally the tightness of the band; a pipe wrench is used on the shaft to revolve the armature. It will be noticed that the forward end plate is screwed down to the lower half only, so as not to interfere with the tension wing nut and bolt.

CUTTING THREADS

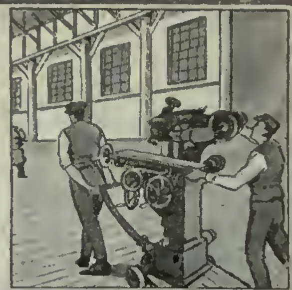
By J. J. DIXON

When cutting thread in a lathe or when getting internal diameters, etc., it is frequently the practice in making internal threads for the draughtsman to give just the number of threads to be cut, not giving the diameter of the top of the thread in internal work. The workman, for example, is given a spindle to turn 3 in. diameter and a thread to be cut on it 12 threads to the inch. Then he is given a nut to make, 3 in. diameter, 12 threads to the inch, to fit to the spindle. I have often seen lathe hands waste a lot of time getting the diameter of the bottom of the thread on the spindle to enable them to bore out the nut the right size for hreading. This can nearly always be avoided by referring to the standard tapping sizes given for ordinary vee threads or sellers threads, as it does not make any difference whatever the diameter the thread is for if the number of threads per inch is given the depth of thread will be the same on any diameter. For example, ⅝ tapping is 11 threads per inch—drill to be used correct for root of thread is .507, subtract .507 from .625 gives .118, which will be the correct amount to leave in bore for threading any diameter having to be cut 11 threads per inch.

Practically all crucible steel castings and also converter steel castings containing over 0.4 per cent. carbon are annealed. Converter steel castings having less than 0.4 per cent. carbon may or may not be annealed according to the service which they are designed for. Coke-fired annealing stoves are customarily used in Australia. The castings are packed in the furnace and the side walls bricked up, or a removable top made in sections placed on the furnace. In only two of the foundries have pyrometers been installed to assist in governing the stove temperatures. So long as annealing ovens continue to be operated by guesswork, it is little wonder that castings fail to meet the standard specifications and the cause of failure has been a mystery.

Putting off an easy thing makes it hard, and putting off a hard thing makes it impossible.

DEVELOPMENTS IN SHOP EQUIPMENT



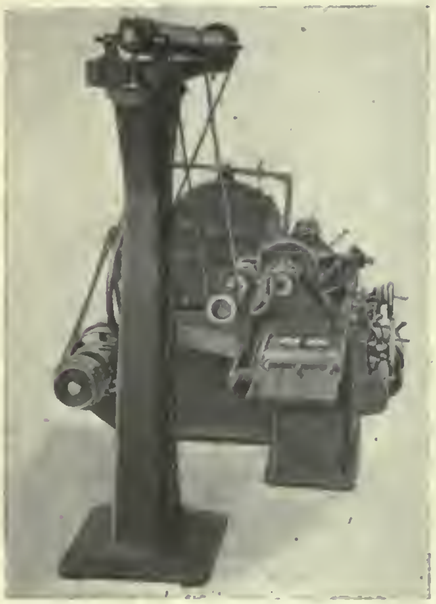
Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.

STERLING CYLINDRICAL GRINDER

TO fill the demand for cylindrical grinding machines of high accuracy and capable of rapid production the McDonough Manufacturing Co., Eau Claire, Wis., have developed a line of grinders, built in various sizes.

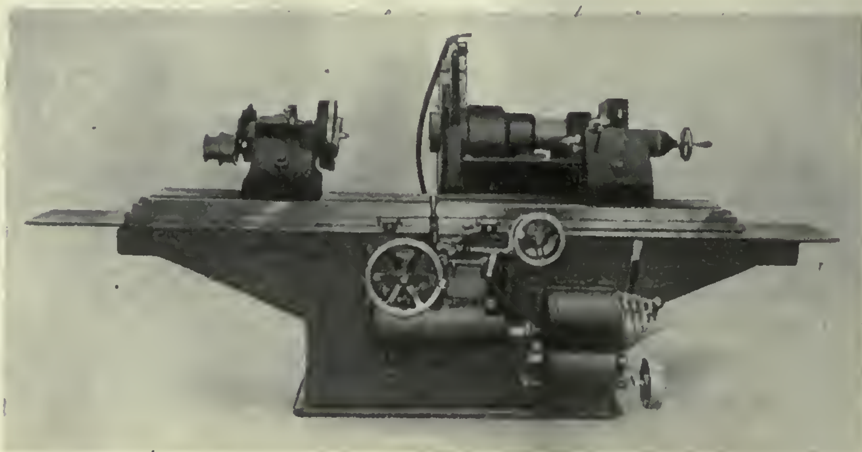
The frame is designed with a three point support which enables accurate work to be performed on all classes of production. All adjustments and speed changes can be made by the operator from his position in front of the machine regardless of the length of work being ground.

The grinder is self-contained, the counter shaft being carried on brackets bolted to the main frame. This arrangement cuts down the floor space required and always preserves the alignment of the counter shaft with the rest of the machine. This construction also permits the use of a shorter belt and eliminates the vibration sometimes caused by a long belt.



END VIEW OF CYLINDRICAL GRINDER, SHOWING WORK DRUM SUPPORT.

The grinder is adapted to all kinds of cylindrical grinding. It will swing work 18 inches in diameter, and the wide swing allowed also provides ample space for steady rests which will support work from one inch to 16 inches diameter and up to 56, 66 or 78 inches in length, depending upon the size of the machine. In addition to cylindrical work, sterling grinders are equipped for cam or crankshaft grinding.



STERLING CYLINDRICAL GRINDER.

The platen is fitted in extra large V and flat slides, which give a wide bearing surface. Automatic oilers insure constant lubrication of the slides. No gibs are used, the table and wheel frame resting on the slides by their own weight alone. The platen is accurately scraped by hand to insure perfect alignment.

The table is fitted to swivel on the platen for taper work. The end of the table is graduated to a one and one half inch angle, with the center line. The machine will therefore grind a taper of an included angle of 3 inches per foot.

The headstock and tailstock have extra large bearings on the platen which ensure rigidity.

The main wheel bearing is massive, accurately ground and runs in closely fitted S K F ball bearings. End play is prevented and thrust taken care of by the use of these bearings. A heavy wheel slide is carried on long, extra wide ways, the weight of the slide holding it firmly in place, and permitting an ease in movement that does away with sticking or sudden jumping into the work.

The work drive is by a drum counter shaft to a radially swinging pulley, which is carried on a quadrant. A conveniently located lever swings the pulley to tighten or loosen the belt. The work drive drum is carried on pedestal set behind the machine and is driven from the main counter-shaft through cone pulleys which permits varied speeds of work. The stand construction for the work drum is an improved method which eliminates heavy overhead apparatus. The stand is of box frame construction.

The cross feed can be actuated by hand or power as desired. The power feed is in the form of a rachet operated by the reverse lever with a variable stroke. An automatic stop is fitted adjacent to the ratchet wheel, thus permitting the stopping of the cross feed at any given point.

The water is supplied from a 16 gallon tank by a standard 1-in. centrifugal pump located at the end of the machine and driven by the counter-shaft.

ELECTRICAL INDUSTRIAL TRUCKS

The lack of labor and the increased wages of to-day would seem to warrant the installation of labor-saving appliances wherever possible in every manufacturing plant, warehouse, railroad, and marine terminal, or wherever ma-

ELECTRIC TRUCKS AS USED FOR 1—HAULING CEMENT FOR CONTRACTORS USE; 2—HAULING OXYGEN CYLINDERS; 3—AS USED IN THE FOUNDRY; 4—FOR HANDLING SEWER PIPE.

terial is to be moved in quantities. One of the main advantages of the truck system is that its route is not limited to a fixed portion of a plant or terminal as is the case with overhead chains or other types of carriers. The trucks illustrated herewith are manufactured by the Crescent Truck Company, Elizabeth, N.J. These trucks steer on all four wheels, giving the shortest possible turning radius, enabling the truck to operate in narrow intersecting aisles and runways. Timken worm and worm wheel transmission is used. S K F self-aligning ball bearings and Timken roller bearings are used in the wheels. The hinged platform, when raised, gives immediate access to the entire driving unit and battery.

The transmission is completely enclosed in an oil type housing and runs in a bath of oil; no parts are exposed to pick up dirt and loose materials from the runaway. Battery capacity is unusually large, the truck being able to run without re-charging at a speed from 5 to 7 miles an hour, with a full working load for a ten-hour day.

The frame is made up of four-inch channel steel, thoroughly braced with large gusset plates, and the cross members all riveted together with one-half inch rivets. The truck wheels are driven through a worm differential, giving positive traction. As the whole driving mechanism is enclosed in a housing and continually runs in oil, it is thoroughly protected from dust and dirt.

The wheels are of cast steel, mounted on tapered roller bearings and well provided for lubrication. The tires are of solid rubber, 25 inches in diameter, with 3 and one-half inch face.

The brake is of the internal expanding type lined with asbestos fabric, which is set at all times and has to be released by the operator's foot. A cut-out switch is so arranged as to automatically break the connection when the driver steps off the platform.

The truck is steered by a lever operating vertically, and is directly connected to all four wheels; this steering on all four wheels gives a turning radius of six feet, and allows the truck to enter the side door of a standard box car and run towards either end. All knuckles and joints are provided with lubricating devices.

The controller is of the drum type, three speeds forward and three reverse, with a positive stop between. The type of battery is optional with the purchaser, being either of the Exide lead type, or of the Edison iron and nickel type. It is of sufficient capacity to operate the truck for a full day's work, or ten hours without recharging.

A typical charge used for crucible steel is as follows: Pig iron, 20 pounds; scrap cast and runners, 40 pounds; scrap mild steel, 100 pounds. The composition of the steel produced by the crucible method depends largely upon the average composition of the charge. The metal, however, absorbs carbon from the crucible and the carbon content of the steel always increases from 0.2 to 0.6 per cent. during the melting.

Dominion Foundries and Steel Review War Work

Enormous Amount of Material Has Been Successfully Handled at the Plant in Hamilton—Appreciation of the Work Done by Sir Joseph Flavelle in Munitions Board at Ottawa

THE Dominion Foundries & Steel, Ltd., Hamilton, has issued the following statement in regard to their war operations:

This company has developed a capacity of 10,000 tons steel per month during the war, and in making this large increase in our capacities for shell work we continually had in mind the conversion of this product into commercial uses after war. A study of the imports of rolled steel into Canada shows in round figures about one million tons per year imported during the years of 1912, 1913, and 1914. This tonnage of steel imported is practically the same as increase in open hearth capacity of all the steel makers in Canada during the war, and the necessary finishing mills for finishing a very large proportion of this open hearth capacity into the shapes required can be built for a roughly estimated expenditure of $30,000,000, which amount is half the value of steel imported during each year for the three years mentioned.

Supervision Needed

The steel business of this country is in need of supervision and direction just such as was had in the shell work, and if the Canadian government will constitute a similar body of men, giving them powers to act, it will result in a development of considerable more industrial and financial value to Canada than the shell work. It will, of course, be done on a different basis of value and margins, but it can be made none the less effective.

We urge the Canadian government to foster and direct her steel industry. Just as sure as this is done Canada will grow in an industrial way.

In December, 1914, we were invited by the Shell Committee to consider the machining of British 18 pdr. shrapnel shell, and, as a consequence, an order for 50,000 of these was taken. Various means and methods of manufacture were studied, equipment purchased, and work commenced early in the year. The first shipment was made in April, 1915, and the manufacture of shrapnel shell was continued without interruption until September, 1917. In 1916 we erected a shop for the machining of 4.5 in. high-explosive shell, but later we discontinued machining and directed our efforts to steel making and forging. Our original order called for only 60,000 4.5 blanks at the rate of 10,000 per month. The first shipment against this order was made during the month of April, 1915, and the order was completed in June, 1915, or in less than half the time specified. By that time additional orders had been placed not only for the 4.5 in. blanks, but for 60 pdr. blanks as well. We continued manufacturing this size until the need was less urgent, when it was pointed out to the Shell Committee that the small sized blanks could best be made from rolled steel, and we discontinued the casting of small-sized blanks and changed over to heavier sizes.

In January, 1916, we undertook to produce 9.2 shell forgings as well as 9.2 in. cast blanks, and were successful in turning out the first 9.2 shell forgings made in Canada. We continued on this work intermittently until the end of the war, and we claim the production record of 39,673 forgings per month. Our best 24-hour run was 1,848 from a single press.

A Forging Record

In the Fall of 1916 we were requested to undertake the manufacture of 6 in. shell forgings, and built a shop and installed furnaces, presses, pumps, accumulators, etc., in record time, and turned out our first 6 in. shell forging the day before Christmas, 1916. This shop operated on 6 in. shell forgings until the war closed, and we have attained a production of 5,280 from two presses in one 24-hour run, our average being about 4.600 per day. We worked with the idea that furnace capacity was the most vital necessity, and with this in mind we installed sufficient furnaces to keep a constant stream of hot metal moving to and from the presses. We found in this way that four presses in operation, with six pumps and two accumulators, we could forge 800 tons of steel per day, which is also a record.

This company manufactured 216,775 tons of steel for shell blanks and forgings, and we forged an additional 30,000 tons of steel furnished by other makers.

Our production process was unique in that it developed the idea of the most direct conversion of shell scrap to shell forgings without pig iron. When pig iron was not available we carbonized with charcoal in our acid open hearths.

After-War Trade

All of our buildings have been erected not only for the manufacture of munitions, but with a view to utilizing them for our after-the-war activities. Each building as it was erected was carefully considered with this in view, and designed in such a manner that it can be changed over with minimum expense for peace production.

Open Hearth Furnaces

At the beginning of 1915 we had two 20-ton acid open hearth furnaces capable of melting 140 tons per day. This original furnace equipment was added to from time to time, until we now have nine 20-ton acid open hearth furnaces, two 35-ton basic open hearth furnaces, and two 6-ton electric furnaces, with melting capacity of 750 tons daily.

Electric Cranes

In 1915 we had 7 electric travelling cranes from 7½ ton 25 tons capacity. We now have 31 electric travelling cranes from 3 to 40 tons capacity.

Rolling Mill

In 1916 a 22 in. rolling mill was purchased and installation was completed early in 1917. This, with the necessary furnace capacity is capable of rolling up to 5,000 tons per month of billets and structural shapes.

Forging Press

At the same time the rolling mill was purchased a 1,000-ton steam hydraulic press was bought and installed in 1917. Later a 250-ton steam press and a 1,500-pound steam hammer were added to this department, and it is now capable of turning out 500 tons per month of forged billets and large forgings for marine engines, ships, locomotives, etc. Two large rough-turning lathes were recently added to this equipment.

The Plate Mill

Early in the summer of 1917 a 26 in. plate mill was purchased with the idea of rolling and shearing agricultural shapes such as plow shares, harrow discs, etc. This was installed and commenced operations in October, 1917, and is capable of producing 1,000 to 1,200 tons per month of harrow discs, plate steel and agricultural shapes. We intend to enlarge our steel plate making capacity and cover a much broader field to the extent of manufacturing 6,000 to 8,000 tons per month.

Financial

This industry made a net saving to Canada of approximately $24,000,000, this figure being the difference between our total sales and imports.

Our pay rolls were approximately $6,000,000 per year, and the resultant pay rolls incident to material purchased and the finishing of our product must represent a very large item.

This war has taught Canada the value of industry, and we again urge the government to direct the efforts of all Canadian steel makers in converting their war output into commercial shapes, and in this manner avoid a clash and ruinous competition. We can decrease costs in one manner only, and that is by specializing, which would follow the proper direction of the efforts of all steel makers in Canada.

What is to be the longest bridge in the world is to be built across the bay between San Francisco and Oakland, Cal. It will be five and one-half miles long and cost $22,000,000.

Has Shell Shop Training Been of Any Use

The Farmer Will be Better Able to Fix His Binder—The Bookkeeper Will be a Handier Man Around the House, But There Are Limits to All This

By ANDREW GLEN, Manager John T. Hepburn, Ltd.

CANADIAN MACHINERY asked several officials and mechanics of representative plants concerning the future of the shell-shop worker. The idea was to find out from these men if the training that had been received in shell work would be of any real benefit to the person at the conclusion of the war when other lines would be manufactured. The following opinion by Andrew Glen, manager of the John T. Hepburn Co., is well worthy of consideration. It goes thoroughly into the case in an impartial and unbiased way, and gives the result of several years of actual observation by a man well qualified to draw conclusions and express opinions.

"PEACE hath her victories no less renowned than war." To guide Canada's army of war workers safely through the dangerous period ahead demands skillful generalship on the part of the government; faithful, unselfish service from our captains of industry; steadiness and discipline from the rank and file and the complete co-operation of all, if victory in the field is not to be robbed of its counterpart at home. Already innumerable committees and councils are working on the plans of campaign for reconstruction. There will be manoeuvring of forces, entrenching, deploying, pioneering, training, scouting nropaganda, but when all is said and done, many individuals will have to settle the problem for themselves. Take for instance, the men who have been on shell operations for the last two or three years. The question is often asked, "What is to be their future?" "Has their work on munitions fitted them for something else along that line?" "Will there be room or welcome for them in the trades to which they would naturally turn?" Well, in the first place, who and what are these munitioneers? A heterogeneous collection certainly, a gold-rush crowd with all kinds and classes represented. Doctors and dagoes, bookkeepers and butchers, furnace men and farmers, teamsters and teachers. Those who had good berths will get back to their ships before they sail away. Many of the others may feel they would like to stay among machinery. Perhaps they like the whirr of it or the feel of it, but anyway, with all its noise and greasiness it may appeal to them more than their previous low-paid pick and shovel work.

ANDREW GLEN

What have they learned? The "management" likes to make its men specialists and unless these men have been moving rather freely around the different plants the chances are that they have been confined to one or two operations and have handled only a few machines. Most of these machines also have been designed for simplicity of operation and can be mastered in a short time. No mechanical ingenuity is necessary to turn out the shells and if the machine "goes on the bum" as they say, there is an S.O.S. call for the repair man. A trifling matter perhaps, but few turn in to investigate for themselves, and they are never expected to do any fitting or setting up. On the other hand, they have made a slight acquaintance with things mechanical; they have been in among belts and pulleys and metal-cutting machinery and are no longer scared of it; they have handled a few tools and have a rude working knowledge of the machinist's kit; they have used gauges and learned the knack of being accurate. How much they have learned really depends upon the individual. One man took to the work like a duck to water and could handle any operation with ease. Another never got over his awkwardness and was responsible for many breakages and much scrap.

So that in the final disposition of these men it is safe to assert that many will never be qualified to enter a machine shop and take their places beside those doing varied machine work or bench work. A few, however, will be acceptable as specialists and in the event of regular machinists becoming scarce in a year or so, may be admitted to full qualification. There is not much likelihood at present, however, that specialists will be required. Machinists will expect to be provided for first, and rightly so. They have the training and it would be inefficient, to say the least, to have them idle while teaching others.

Wherever those munition workers go, even if they return to their former occupations, the experience gained during their war work will undoubtedly not be lost. The farmer will be better able to fix his binder or his gasoline engine, the bookkeeper will be a handier man around the house and the teamster may aspire to driving a truck.

OUR idea of explicit confidence is the youngster writing letters to Santa Claus or the wife who believes everything her husband tells her.

DON'T fool yourself. Your job's pretty much like your pocket. You'll get out of it just about as much as you put in. If you don't put much into it you're pretty sure to pull about that much out.

SOME folks are inclined to throw up their fists and say, "Good land, what will we do when all the soldiers get back home?" Well, we were getting three meals a day before they ever went away. Some people are grouching so much about the soldiers coming back that one might suspect they were wishing the war might continue indefinitely.

The Land's the Big Chance

THE world is hungry. It's so hungry that it's not going to have enough and to spare for some years to come.

What does that mean to Canada? Everything. Although this country is an industrial one to some extent, we can't get away from the fact that the land is our big chance.

Canada has never had enough farmers. Farming is our one and only way of producing new wealth. If a man puts a bushel of potatoes in the ground and digs out a dozen bushels, he has put into the world's market new wealth to the extent of eleven bushels of potatoes.

Western Canada is essentially agricultural. The trouble with that country has been that it was, in its good years, jammed to the neck with loafers. There were too many people making money without putting the equivalent back into the market in return. They were, in fact, camping on the necks of the people who were performing some useful work.

The people of Canada have their chance right now to do a service to the world, and in so doing solve their own national problem by turning the trend of population to the land.

In the mad rush for export trade, for manufacturing outlets, let us keep a sane censorship over our activities and see to it that we specialize first in the great industries that will build for us a real foundation.

Canadian manufacturers are just as much interested as any class in seeing that Canada shall build up and maintain a strong and prosperous agricultural community. If this is not done, then all else will simply be built on a false understanding and a deceptive basis that will have no more stability than a house of cards.

Facing the Loss

FIRMS that have made money during the war time now have a chance to show if they are made of the same good stuff as the men who went overseas.

One Toronto machine tool dealer who, at the close of the war finds himself stuck with a large stock of munitions supplies and tools that are worth only their scrap weight, put the case correctly when he said:—

"We are going to lose some money on this stock, and the only thing to do is to face the thing right now, accept the share of reconstruction that falls to us, and get rid of the last traces of war in our business. Let us take the war years and the loss we face now. Add the gains, subtract the losses, and we're still ahead of the game."

The trouble is that a good many Canadians were never near enough the battle line to get a whiff of smoke. Their property was never damaged, nor their chattels confiscated. They apparently do not realize how extreme was the situation for the Allies right up to the 18th of July of the present year. They don't want to take time to think seriously of the fact that this country hung in the balance between being handed as plunder to Germany and being allowed to pursue its course and take its place among the free nations of the world.

The stay-at-home section of Canada has its chance now to show that it is worthy of the sacrifice that has been made for it in Flanders and in France.

It can shoulder its share of any loss that is going to result from the cessation of war work, and see to it that that part is well cleaned up before the armies return from overseas.

See to it that we get back to normal as quickly as possible, and do it gladly, and not with a whine or a whimper.

A HAMILTON gentleman called at this office a couple of days ago. Discussing the money that some people had made out of the war, he thumped the pine table with his horny fist and said, "They have passed from pinching poverty to plutocratic prosperity." Shakespeare's double superlative, "the most unkindest thrust of all," hasn't much of an edge on that.

PUNCH, OR THE LONDON CHARIVARI.—August 14, 1918.

VON POT AND VON KETTLE.

GERMAN GENERAL. "WHY THE DEVIL DON'T YOU STOP THESE AMERICANS COMING ACROSS? THAT'S YOUR JOB."

GERMAN ADMIRAL. "AND WHY THE DEVIL DON'T YOU STOP 'EM WHEN THEY *ARE* ACROSS? THAT'S YOURS."

CONSTANT STUDY IS PRICE OF ALL PROGRESS

H. T. Manes is New Foreman of the Massey-Harris, Toronto, Tool Room

By A. J. TALLMAN

I LEFT H. T. Manes and hurried to overtake one of his men. We boarded the same car.

"What do you think of Manes?" I asked.

"Manes?" the man repeated; then, comprehension dawning: "Tracey you mean? Why, we'd do anything in the world for Tracey."

"Is that his first name?" I questioned.

"I don't know," the man said. "It is the name we call him."

H. T. Manes and his son of the 10th Battery, 3rd Brigade Artillery, C.E.F., France.

And then he talked about work in the Massey-Harris Company's Toronto plant and about H. T. Manes, who is foreman of the tool room; and I recalled how Manes had told me that he was quite alone in the world from the age of nine.

Indeed, it is possible that my travelling informant found me inattentive, for I was picturing the man Manes as a lad deprived of home influence, counsel and encouragement. I was feeling the hardships and lonesomeness that he must have known, and I was thinking that it was in a sense wonderful that he with his fifty years should not look a day older than forty.

Tracey Manes was a young man of twenty before he went into the tool room of the Massey plant. The last year of his apprenticeship he was four years older and making a dollar a day.

About a year later he went with John Perkins & Son, who at this time had a plant on Front Street East, Toronto. He was here only four months when the fates that concoct disease germs knocked the chip off his shoulder.

"It was Christmas before I was able to be around again." he told me. "I went back to Massey's, where John Orr was foreman of the tool room. The tool room comprised two lathes, one shaper and one milling machine.

"Then, in 1906, I went with the Canadian Fairbanks-Morse Company. Here it first came home to me that a man can either lag at his machine or really produce and that upon the choice he makes depends his future. The output of the lathe I operated doubled. Did I work harder or longer? Neither. I simply kept my mind on the job and worked as fast as I could.

"Lagging is the result of indifference or inattention. It grows into a habit. It is one of the habits I try to keep our apprentices from contracting. Don't think that I crowd them with work. They're free to stand around for minutes at a stretch, to look about them and see how other work is done, for that may do them some good. But when they're on work that they know perfectly, I want it done as fast as they can do it—and for their good.

"But to come back: I was just ten months in the Fairbanks-Morse shop when strike talk started. The manager knew what I thought about it. He came to me the day before the strike was called.

"'What do you purpose doing, Manes?' he asked.

"Leaving," I told him.

Manes worked for the Canada Foundry Company four months; for the Elliot Paper Box Company three years. He was with this latter firm when its plant at 333 Richmond Street was burned. He built the first, and probably the largest paper-corrugating machine used in Canada.

In 1911 he returned to the Massey plant which had become the Massey-Harris, starting on lathe work. A year later he was made assistant foreman, and in 1915, foreman of the tool room.

No; he didn't do it by experience alone. He read technical papers and technical books. He educated himself. The library and desk in his home aren't there for show.

"Tracey" his men call him, but in the Harbord Street Tech. he is Mr. Manes. And the young men and boys who attend on the nights that he is instructor have for teacher a man who thoroughly knows his subject, and a man who has taken the buffets of life with a smile.

Speakin' of Meals

WHEN folks go in to get a meal at some big, smooth hotel, you'd think that half the eatin' there was done by lookin' swell. You prance upon a carpet floor and when you take a seat, 'bout sixteen waiters swoop around to hand you out a treat.

Why one galoot he gets a pail and pours you out a drink, another whisks a battin' card, 'twould make you gasp and blink—another gets a napkin out and ties it round your neck, you'd think you'd get your puddin' and yer soup served by the peck.

They put six knives a-side your plate, likewise six forks and spoons, they start the band a-tootin' at forty kinds of toons.

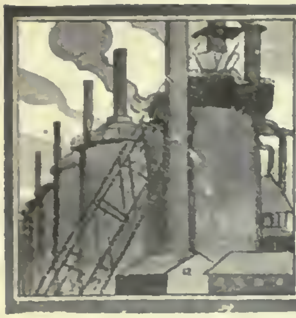
Old ham and egg, she's 80 cents, consomme 50 more, you clutch your seat to make her sure you're settin' on the floor.

By heck, there's silver dishes, there's folks a-bobbin' round, there's elegance jammed to the roof a-startin' from the ground. You're most a-scared to dig right in and stoke it as of yore, for fear you'll send the trappin's a-flyin' on the floor.

Ah, give to me the old-time meal, with just one set of tools, and cart away them boiled front doods and all the other fools. And let me saucer out my tea and eat pie with my knife, and do them other grand old tricks, they are the salt of life.

And let me have a kitchen fork to pick my hollow teeth, don't tempt me with the trinkets for fear I come to grief—them good old meals in good old ways is pleasin' night and noon, more so than sixteen waiters a-prancin' round the room.—ARK.

IS the government or the Food Controller afraid to tell the farmers that they must not chase the price of eggs up to a dollar a dozen? The squeeze is felt in the cities while the farmers run wild.



MARKET DEVELOPMENTS

Still Producing on American Shell Contracts

Although Shipments Are Not Being Made From Plants to Coast Points, Machine Tool Dealers Find That They Have Some War Stock on Hand Yet Which is Only Good For Scrap

PLANTS in Canada handling American munitions orders are still operating as though there was still a war on. It is one of the anachronisms of the situation that shells are still being machined at the same terrific speed that marked the days of the war's greatest mechanical production. This state of affairs cannot go on for any great length of time. In fact cancellations are anticipated in some cases very shortly. Contracts on which production was not commenced went first, and it is reasonable to expect that the others will soon follow. In United States cancellations and adjustments pending at present are estimated at some billion and a half dollars. Shipment is not being made to U.S. shipping points, but shells are now stored here in many cases. Some of the plants have ceased their Sunday work.

Those in close touch with the situation warn the public against paying too much attention to the first rush of peace orders that reach the mills as they cannot be accepted as a safe criterion of the trade that will follow. There are industries that have been starved for steel, and the accumulated orders of these concerns will make quite a showing for a time. In regard to prices it is unlikely that United States authorities will continue their effort for any length of time to stand behind the steel market. There is a decided tendency on the part of the big government purchasing commissions, the Railroad Administration and the Fleet Corporation, to buy in the lowest market, and if this is carried to any great extent it will mean that the steel industry will have to pass very quickly to a peace time competitive basis, and do so on its own merits.

Machine tool dealers and those who have handled war supplies find in some cases now that they are rather heavily stocked with machinery and stock that is worth little more than its weight in scrap. There have been several requests from shell shops to have dealers relieve them of this material, but it is unlikely that this will be done. There are some lines of supplies that are worth only one-sixteenth now of their value in the days of war production. There are no commercial lines to which they are adaptable.

Scrap dealers are passing through a period of stagnation of trade. There are no sales either way, in or out of the yards. Several Toronto dealers during the last week have sought Chicago or New York as an outlet for stocks held here, but they find conditions practically the same there.

Pig tin sales are made in New York at 71c, which is a drop of over 30 cents per pound in the last few weeks. While other prices have not actually moved to lower levels the prospects are that they will very shortly.

MONTREAL MARKETS REFLECT CONFIDENCE IN THE FUTURE

Special to CANADIAN MACHINERY

MONTREAL, Nov. 27.—The announcement that operations on the British shells would be discontinued in the very near future is now becoming evident and many plants are cleaning up on their last orders. In some instances plants here have been instructed to stop operations before the completion of their order. The general arrangement, however, is that the process of finishing will go on so that in most cases the work on British contracts will end before the close of the year. It is expected that operations on the American shell contracts will continue for some time but this appears to be very uncertain, although no plant here has been advised to the contrary. General conditions reflect the unsettled state of business both here and in the States, and in all directions the policy adopted appears to be one of watchful waiting. The shipbuilding interests and the marine shops have already absorbed a number of the men that were working in shell plants, and it is expected that the New Year will see new enterprises established along the lines of domestic activity. The markets are all more or less unsettled and no definite move has been made for a readjustment, but in view of the magnitude of the operations it is likely that this will take some little time.

Priorities off but Trading Quiet

The steel situation here has assumed a condition that is rather difficult to define and few dealers will offer a prediction as to the early future, but think that an easier market should be the outcome. The week's developments have virtually resulted in an open market, as all priorities are now discontinued. This, however, has not resulted in a stampeding for steel, although more business is reported in domestic lines. The situation to-day involves problems that were non-existent a few weeks ago, when the end of the war was not in sight. A month ago, with an open market, many consumers would have jumped at the opportunity of getting steel supplies, whereas, at the present time, everyone is extremely cautious in the buying of material. It is the opinion of some dealers that the American Government will continue to maintain a controlling price on the sale of steel, particularly plates, as a sudden withdrawal of the fixed price might result in a runaway market. Starving conditions have been a feature of the automobile business for a long while and if the price on sheets was suddenly left to the discretion or prudence of the producers, it would likely be found that automobile demand would result in a much higher price than that now effective. It is believed here that the War Trade Board will be retained for a further period to assist in the re-establishment of normal conditions. Production of steel in this district, for British munition work, is now a thing of the past and in a short time the same will likely apply to

American business. Normal quotations are the order of the day but lower levels are looked for this coming week.

Little Activity in Metals

The waiting attitude is the dominating feature of the present situation, and while to some extent the market is an open one, conditions are such that little actual difference is apparent in the general operation. The fact that copper prices in the States are fixed to the first of the year acts as a steadying factor, which is naturally reflected in the trading here. It has been reported that the British Government has recently placed orders for about 20,000 tons for reconstruction purposes, and this has been of considerable influence in adding stability to an otherwise unsettled situation. The tin situation is one that apparently requires judicious handling to avoid a panicky aftermath. As stated by one of the dealers here, this metal coming from the far East is often three months in transit, so that the policy of the War Industries Board will likely be to have a gradual readjusting of this market to avoid conditions that might create serious chaos. It is thought, therefore, that the decline to lower price levels will not be such as to disorganize the market. The spelter situation is practically unchanged, demand is lighter and dealers are apparently awaiting developments. The same might be said of lead, production is not excessive and consumers are looking for lower prices. Antimony is a typical war metal and as such has felt the cessation of war work quite heavily; the poor demand has been followed by a decline of 3 cents, the price quoted being 12 cents per lb. Operation in aluminum are still under certain regulations and in consequence the market is very firm.

Complex Tool Situation

Activity in the machine tool industry has been more or less disturbed since the cessation of hostilities, and as a result of the cancellation of many munition contracts and the curtailment of others, the trade has become somewhat disorganized. Many builders of machine tools who have been making machines for shell plants, have received instructions to suspend operations. In some cases efforts will be made to have the purchaser accept delivery, but the general supposition is that the Government War Boards will decide on some arrangement whereby satisfactory adjustment may be made for all parties. The tendency appears to be to suspend all unfinished war work affected by recent developments, and unless tools are urgently requested for delivery, they will remain unfinished pending a settlement. Few of the dealers here have been hit with the cancellation of tools, as the buying of late has been almost exclusively for American business, and work on this class of shell will likely continue for some time. The sudden falling off of munition work has been reflected in the general supply business, and activity in this demand has shown a marked decrease. However, a fair volume of regular sales are reported and dealers are generally optimistic. Many shell plants are in the market for the disposal of their equipment.

No Market in Scrap

Operation here in regard to the trading in scrap are confined to immediate requirements where the placing of the material is assured before the purchase of the same. "We are virtually flooded with offers of old material but invariably the price asked is abnormally high and sales are not made," remarked one dealer. "We have just received an offer for the purchase of a quantity of copper scrap but the price mentioned was out of the question. It is very improbable that we would even accept material at prices quoted unless we were assured of an immediate market for the same." This seems to be the prevailing condition of the market, and heavy trading is at a standstill. Speaking of copper, Frankel Bros. stated that 18 cents was just as good as 21 cents, as present quotations could only be given as a nominal guide, the actual assurance for the prompt transfer of the metal being the essential requirement. Copper is quoted one cent less this week, the range being cents was just as good as 21 cents, as heavy. Stove plate is the only other scrap affected, the price asked being \$28 per ton, a decline of \$2 per ton. While most scraps are nominally firm dealers anticipate a decline to lower levels.

POINTS IN WEEK'S MARKETING NOTES

U. S. government is not yet cancelling orders on which work has been started, but where deliveries have not been yet made, cancellations are in order. It is estimated—that cancellations and adjustments to date amount to a billion and a half dollars.

Practically speaking, the entire priority and preference system in the United States is wiped out.

To-day the insistent demand for steel comes from jobbers and builders of automobiles. Experts who look well into the situation warn the public against believing that the first "flash in the pan" rush of peace orders is a criterion of the volume of trade to come regularly to the mills.

United States government is not inclined to spend very much money in high-priced material in order to sustain the steel market. The railroad administration and the fleet corporation both show a decided tendency to buy at bottom figures.

Several dealers in machine tools and munitions shops supplies find that they are quite heavily stocked with war material that will be worth only its scrap value. Munitions plants in several cases have approached dealers asking them to take back war supplies, but this will not be done.

Imperial Munitions Board is starting to dismantle its plants, the aviation division being the first to go. A large quantity of machine tools will be brought on the market.

Scrap dealers are out of the market this week as they were last. Dealers who tried the Chicago and New York markets for an outlet were informed that they were wasting their time in the effort.

SOME POWER NEEDED TO STABILIZE PRICES

Trade Thinks That Time is Not Opportune For Removal of Restrictions

TORONTO.—The removal of all restrictions on trade, and the making of it unnecessary to secure licenses or permits is expected daily. There is a strong feeling in Canadian trade that the War Trade Board should not cease office so soon. There is evidently a need right now for some such organization to remain in control and stabilize prices for some time to come.

Munitions contracts on American order are still running as though the war were still at its height, the only difference being that shipment is not now being made to coastal points, but the product of the shops in some cases is being stored at the point where the shell is finished, a railway embargo making this necessary.

The Machine Tool Trade

"There's a man down stairs who wants to buy a lathe." "Bring him up," came the quick answer, and the customer had the right of way. A man who is out to buy lathes or any other machine tools this week in Toronto is a welcome visitor. It is too early, the trade points out, to expect that the demand for equipment for other than war shops shall have commenced to come in. In many cases the dealers are having a pretty busy session just now trying to get their cancellations straightened out and the necessary adjustments made. For some time past some of the larger dealers in United States would not sell at all with a cancellation clause in their contracts. This may have resulted in the loss of a few sales, but it works out well now, in that these firms have no cancellation or adjustment problems.

There are several concerns that will have to take some time to have all their adjustments, following cancellation, made, as they have had work farmed out in a good many shops all over the country, and it is now in all the varying stages of completion.

Supply houses are still selling to the machining plants, although it is hardly necessary to state that the sales are all made pretty close to the wind, as these shops are mapping it out that they shall not be stuck with any of the supplies that are purely war equipment. It seems somewhat of an anachronism to see shops with American orders turning out shells the same as when the war was on. Some of the shops have shut off Sunday work, but otherwise the three shifts are coming and going just the same as they have been for several years. These shops seem to think that they will be told when to quit work, and in the meantime all they have to do is to keep on producing. Shells on American order are being stored at the Exhibition grounds in Toronto instead of being sent from here to the shipping point for American goods. This is due largely to the fact that there is an embargo on against such shipments taking up car space at present.

The Scrap Metal Trade

The word scrap metal trade is simply nominal. It may be called that because there is nothing else to call it. But there is no trade in connection with the whole works. There is little doing. "Every figure that you quote to-day," stated Frankel Bros. this morning, "is normal. You might be able to put a deal across at some of the figures, and then again there is the big chance that you could not." One of the dealers called up Chicago the first thing this week to find out if there were an opening there for a fairly large amount of material he had in sight. The answer was "Get off the line. You might as well talk to the wall. You're only wasting our time and your own."

Pig tin is coming down and will soon be classed as lowly metal. It has had a rather wild and meteoric career during war times, but its palmy days are past. Quantities are sold in New York now at 71, which is really a drop of about 34 cents in the last two weeks. The chances seem to be that it will keep on in this direction until it has reached a level at around 50c, and it may stay there for some time. Even that figure is well above the pre-war price. For a ten-year period the price of tin has been about 37½ cents, not counting war time inflation.

The Matter of Prices

A good many firms are offering to sell to the warehouse men instead of buy from them. Several places using sheets had contracts with the Imperial Munitions and they have this material now and want to place it. There is an element of uncertainty in the situation this week that is quite noticeable. With the removal of restrictions of trade it is hard to forecast which way prices will jump. It seems very certain that all such things as licenses, priorities and ratings will go by the boards very shortly, and the trade generally is not certain that it is well that this should be the case. One dealer took the case of sheet tin. The government price was $7.50 per box, and when the restrictions were taken off the price at once went to $10 per box. "That price jump," stated one warehouse man, "is not based on common sense. It is simply a frantic effort to keep up the morale of the trade and get what business they have on their books out at a good price."

He also took the case of steel bars, which form one of the greatest lines in the trade. "The present Pittsburg price is $2.90, and the present Canadian price is $4.15. That means, with freight and duty a difference of 55c per hundred against the Canadian maker. There is a danger that Canadians will cancel their orders here and place them in the lower market. There will have to be more of an equalization than that, or we will have hard work keeping orders for the mills here.

CANADIAN MACHINERY asked the sales manager of one of the largest Canadian plants how he would explain that situation. "We won't explain it," was the answer, "we will meet the American mill on the basis of dollar for dollar. We expect to do it and I am certain that we can do it."

Officials of the United States Steel Corporation that are planning the big mill at Ojibway are sending out letters just now to dealers and users of steel products making inquiries as to the amount of material that is being used in various lines. The idea apparently is that they should be acquainted with the requirements of this country before starting operations.

IMPERIAL MUNITIONS BOARD PUTS LOTS OF TOOLS ON THE MARKET

THE Imperial Munitions Board has made the announcement that they are going to liquidate their entire business properties as soon as possible. In fact, some days ago at Ottawa, Sir Joseph Flavelle stated to this paper that the Imperial Munitions Board existed now simply for the sake of going out of business.

The first break will likely be made in the aviation department, which has a number of well-equipped establishments, where a large amount of machine tools and supplies have been put in. As a matter of fact the lists are being prepared now, setting forth the machinery that is contained in these shops. These lists will be forwarded to the various places where purchases will most likely be made in the near future. When the dismemberment of the big establishments also starts, the chances are that there will be some crowding of the machine tool market. A number of the machines in the possession of the aviation department have never been taken out of their crates, and others, although they have been placed in the shops, have never been used.

Offered to Sellers

A representative of CANADIAN MACHINERY talked with one of the officers of the board at the Imperial Oil building on Church St., where the headquarters of the aviation department are situated. Work was in progress in the offices there in connection with the drawing up of the lists.

"We are getting ready now to offer the equipment in all the shops that are under the direction of this department," stated the official. "At present we have the following shops that will be dismantled and sold: Deseronto, Camp Borden, two at North Toronto (Leaside and Armour Heights), Beamsville, three in the city (the engine repair park on King street, the airplane repair park on Atlantic avenue, and the motor transport on Dupont street."

"How about the dealers who sold the equipment? Were there any cancellation provisions with them?"

"In some cases," replied the official. "As a matter of fact we followed the following programme in every case: The manufacturer of every machine had a chance to take the machinery back, but in no case was this done. They claimed they did not want them, and so we are going ahead to dispose of them by ousting them."

General Purpose Material

There is considerable general purpose machinery in the lot, and the chances are that the throwing of it on the market at this time will have a tendency to flood the situation for a time. Speaking of this aspect of the case Mr. F. W. Evans, the Toronto manager of the Canadian Fairbanks-Morse Co., stated to CANADIAN MACHINERY that there was no way out of the situation. "We have to look at the thing as it actually is and face it. We have been at war for four years. All the firms have done a big business. They have not lost money On the other hand they have made it. Now, in a period such as we are passing through we can expect to encounter situations where we are not going to make money. On the other hand we can expect to meet situations where we will lose money. But then, take the whole four years, put your gains down one side and your losses below them and subtract, you will find that you have a good margin left, and that is the only way to deal with the present situation."

Might Store Machinery

From another source the suggestion came that as the Canadian government had a commission overseas looking for trade, it might be a good idea to store some of the equipment, and hold it in preparedness in case something should turn up that would need equipment in a hurry. However, it does not seem likely that such a scheme will be entertained, as the Imperial Munitions Board is apparently out to get rid of their entire stock, and trade in as short time as possible. From what CANADIAN MACHINERY could learn, the machine tool dealers were not counting on buying in any of the equipment from the Imperial Munitions Board.

Where the Loss Comes

"Here is is something you should have," remarked the manager of one of the big Toronto concerns to CANADIAN MACHINERY to-day. "A number of the munition plants around the country that have had their contracts cancelled are writing to us asking if they can be relieved of the supplies that they have left over, and their accounts credited with the amounts. In one case a firm wrote in here giving a list of the material they had. They stated that on receipt of word from us they would ship this material and have it replaced by standard supplies. They got the word from us, but not in the way they expected. We are stuck ourselves with a fairly heavy stock of supplies that will not be any use beyond the value of the material that is in them. The munitions plants," stated this dealer, "should be prepared to shoulder their share of the losses. We certainly do not intend to take back any of these goods where a bona fide sale has been made. We took the big chance in carrying a big stock of this stuff all the time so that the munitions plants would have a good supply to draw from all the time and delays avoided in production. Now that the demand is off for these special kinds of supplies, it's up to them to shoulder and absorb their small loss, and we will have to do the same in a much larger way. Such things as hobs, chasers, etc., will not be used in any operation that we know of at present, and we are certainly not going to absorb the loss that should fall on the shell shops." A hob that was worth about $16 a few days ago was much sought after in the shell world. To-day the dealer turns it over, gives it an imaginary weighing balance in his fist and reckons that the high speed in it will bring in a pinch about one dollar. It's the old case of the Bryan 16 to 1 ratio, with the man who put up the $16 on the losing end.

PITTSBURGH HEARS PRIORITIES WILL BE SWEPT AWAY NOW

Special to CANADIAN MACHINERY

PITTSBURGH, Pa., Nov. 28.—The policy of the government as to reconstruction is probably as well defined as such a thing can be only a fortnight after the sudden cessation of hostilities, but it does not follow that the course of affairs will follow the desires of those who have undertaken to regulate matters. Necessarily, the powers of the government are much more limited than they were in the war period.

As to cancellations of war orders, the government continues to follow the policy outlined in last report, of refraining from cancelling orders on which work is being done, if that would result in idleness of plants or workmen. How long this policy can be continued is naturally a question, for the object is to allow activities to change from the making of war to the making of peace material, and it cannot be determined how soon a sufficient volume of peace work for the iron and steel industry will develop. The government can keep up the war work for a time, but of course not for any great length of time.

Cancellations of orders on which work had not been started has proceeded very rapidly. The cancellations and readjustments to date, including all classes of material, probably amount in value to $1,500,000,000 or more.

Priorities and Preferences

Practically speaking, the entire priority and preference system is wiped out. The formal order is that the preference list is discontinued and the priorities, both individual and automatic, are annulled, except orders for the Navy Department, the Fleet Corporation, and railroads and telephone and telegraph lines. With the pressure removed by other priorities being discontinued, no producer will have any difficulty in making deliveries at times desired by the activities still accorded priority, hence those priorities are merely a safeguard, and deliveries would probably be made just the same if there were no priorities at all. If demand should remain such as to keep the mills continuously busy, the decision as to which material shall be shipped first is left to the mills, thus restoring the old order of things. In normal times the mills do not fill their orders in rotation, but in accordance with their knowledge of the needs of their customers, the object being to maintain the operations of all customers as equitably as possible.

Character of Present Demand

There has developed what appears to be quite an insistent demand for steel, but this demand may be misleading if it is not scrutinized carefully. Naturally the first flash of demand, after the mills have been crowded to capacity, and more, for a trifle over three years, many consumers have been starved as to steel, and prices were at a war-time rather than a peace-time level, cannot be expected to reflect in either volume or character, the demand that is to be experienced in settled times over a period of years. That there will be for quite a while say from two to five years, a demand for approximately all the steel the industry can produce, is the common opinion, but this demand cannot necessarily be expected to develop at once, because the matter of price plays such an important part. There are all classes of buyers as to the period in which they expect to liquidate their purchases. As illustrative, two extremes may be cited, the jobber who has customers demanding material at once, and who can, perhaps, buy from a mill and have the material sold and paid for within thirty days, and the investor in a highway bridge, certain to bring in revenue for 20 years, and which, therefore, can be undertaken with the idea of its returning the capital invested in installments over a period of twenty years. The one buyer of steel need scarcely look ahead thirty days, while the other is disposed to look ahead twenty years. A well rounded-out demand for steel requires that there be buyers of all descriptions.

To-day the particularly insistent demand for steel comes from jobbers and from automobile builders. Other classes of buyers are not conspicuous in the market. The jobbers are importuning the mills and mulling over stock lists, being glad in some cases to take even a single ton of material that may chance to be in a mill stock. The jobbers show no disposition to build up their stocks except in items that are very deficient, and their general policy is to have their inventories as light as possible on January 1 for several reasons, one being the manner in which profits and taxes for 1918 must be computed. As to the automobile builders, there is believed to be a heavy demand for cars, and the makers have notified the public that they must not expect reductions in prices of cars before the end of the spring selling season. For the cars to be built in the next few months the automobile builders need not be particular as to prices paid for steel, for they know they can make a profit in turning into cars the steel they can buy on the present market.

The present flash of demand, therefore, does not bear the earmarks of permanence. The real issue is as to when the investment buyer will come into the market, when there are buyers of steel who expect to secure the return of their capital in periods of five, ten and more years. Such buyers will wait if they think the investment will cost them 10 per cent. less six or nine months later. They want to see a rising market rather than one which is likely to decline if it moves at all.

Price Prospects

Steel makers presumably know their own business, and for several weeks past their talk has been that the government ought to set minimum prices for steel, for the transitionary period, to replace the maximum prices that have hitherto obtained. There is every evidence that the steel trade expected a slump in prices if there were not artificial control. It has become established, however, that the government will not and cannot set minimum prices. At first it was thought the Sherman law, against conspiracies in restraint of trade, might stand in the way, but the second thought has been that even if it were not for that law, the United States government cannot set minimum prices when it has no means of punishing anyone who would cut prices and thus violate the order. The government has been rather strenuously engaged of late in an effort to prove to Germany that it was not "bluffing," and it would hardly be in keeping with its traditions for it to undertake now to issue orders which it could not enforce. This new thought leaves it that the War Industries Board may continue to fix maximum prices for a time, as it has done hitherto. The present limits were set to run for deliveries through December 31, and prices might therefore be fixed in the next few weeks to run for the first quarter or first half of the new year. The common expectation in the past few days has been that this will be done.

THE WEEK IN INDUSTRIAL HAMILTON

Special to CANADIAN MACHINERY

HAMILTON.—In the death of George Brannum Dowswell, which occurred at his residence on the night of November 20, Hamilton industrial circles have sustained a distinct loss, as he was one of the city's pioneer manufacturers and always had its industrial development at heart.

Born in Pickering, Ontario, 68 years ago, he spent his early years at that point, and later came to Hamilton, where as a young man he showed a strong bent for things mechanical, and also gave much promise of going far in his chosen field, as he had a fund of executive ability and was a splendid organizer.

About this time there was a great demand for what were then known as "modern laundry utilities," such as wringers, mangles, tubs, etc. Young Dowswell had the foresight to see what a splendid field there was to be developed in the making of these articles, and he became identified with Mr. J. Cummer, now of Toronto.

The Dowswell Manufacturing Company was formed, and from the start, under the careful management of Mr. Dowswell, its success was assured. For a good many years Mr. Dowswell was president of the company. Later a reorganization was effected, whereby Mr. Cummer withdrew, and the new firm was known as Dowswell, Lees & Company. The same policies were adhered to, with the result that through Mr. Dowswell's efforts the company became one of the best known in Canada in its own line.

Of late Mr. Dowswell's health had become indifferent and he was obliged to take a less active part in his business affairs, which he entrusted to his junior partner.

By religion Mr. Dowswell was a Methodist, and a staunch member of Wesley Methodist church. It has been said of him that he was "a truly consistent Christian, who carried his religion into his daily life, without parading it."

Mr. Dowswell was well known fraternally, having been a member of Acacia Lodge, A. F. & A. M., and also took an active part in the affairs of the Ancient Order of Foresters.

Of a family of twelve brothers and one sister, only one brother, Fred, of Hamilton, and his sister, of Dresden, Ontario, survive, besides his wife and one daughter, Mrs. Hebert S. Lees.

The funeral took place from his family residence on Saturday afternoon.

WANT PRICES TO BE HAULED DOWN NOW

Hamilton Firms Think That Ottawa Should Act on Their Behalf Right Away

Hamilton.—While those Hamilton manufacturers who have been working almost exclusively on munitions since the outbreak of the war are not in anywise pessimestic over the future, it can hardly be said of them that they are exuberantly optimistic. The apparent failure of the government to appoint war boards to stabilize the prices of various materials is assigned as the chief reason for this feeling of uncertainty that exists.

The chief grievance of those Hamilton manufacturers who were questioned concerned the utter failure of the government to do anything to control the price of pig iron, a material that enters into every form of manufacturing. It was pointed out that in the United States pig iron has been selling for $33 per ton, while throughout eastern Canada the price has varied from $46 to $50 per ton.

In the face of such a disparity as this, Hamilton manufacturers want to know how they are expected to compete in the foreign markets with their American rivals. On products in which there is little material and more work, the disparity in the price of pig iron is not so keenly felt, but on products where the material is in the preponderance over labor, the disparity makes things very difficult; indeed, one manufacturer said it was fatal to the efforts of Canadian manufacturers who had an eye on foreign trade. "We just haven't got a chance at all, he said. William E. Blandford, secretary-treasurer of Brown, Boggs Company, said that the difference in the price of scrap iron in Canada and the United States was also acute. The Canadian price was $40, a figure which he held to be outrageous.

The grievance of local manufacturers was all summed up in Mr. Blandford's apt words: "If the government expects us to come through the period of reconstruction without difficulty it must do its part by stabilizing prices, otherwise conditions are not going to be so good as is expected. Reconstruction is not a mere formula that is going to work out everything itself. There must be war boards to keep things steady for months to come. How can we be expected to compete in the foreign markets against American manufacturers with the present disparities existing?" he asked.

Should Buy Machinery

Mr. Blandford, as did also several other manufacturers, said he was strongly of the opinion that the government should purchase the munition equipment and store it against the time when it might be needed again. The United States government was doing this, and in doing so was acting wisely, he thought.

Mr. Blandford said there was no doubt that many single-purpose lathes which had been used for munitions would have to be scrapped.

In the last issue of CANADIAN MACHINERY an item apeared in the Hamilton correspondence stating that the Canadian Cartridge Co. will make steel barrels, and also stating that "This company will be the only one in Canada to make steel barrels."

This latter statement is, of course, not correct, as the Smart-Turner Machine Co., Ltd., of Hamilton, have been manufacturing steel barrels for the past four years, and have developed a substantial industry in this particular product.

CANADIAN MACHINERY regrets that the statement should have appeared in the way it did, and assures the Smart-Turner Co. that it was entirely an error on our part.

HAMILTON GOING AFTER EXPORT TRADE

And For That Reason Lyons Fair Will Be Centre of Interest

Hamilton.—Keen to develop all the foreign trade they can possibly handle, more than a few of Hamilton's manufacturers have already taken steps to be represented at the annual fair to be held in Lyons, France, on March 1, 1919.

The greater volume of the output of Hamilton's industries in pre-war days was of a domestic nature, and little or no attention was paid to export. But if the reconstruction period is to be passed through without difficulty, it is argued that manufacturers will have to pay the utmost attention to export and foreign markets.

At a special meeting of the local branch of the Canadian Manufacturers' Association, the importance of being represented at the Lyons fair, either by exhibit, catalogue, or photographs, was impressed on the minds of local industrial heads, and the result was that several signified their keenness to heed the speaker's advice.

If there is one country in Europe that will have to be built up, that country is France, it was pointed out, and local manufacturers were not slow in appreciating the fact that the best way they could get samples of their goods placed before the buyers on the French market was being represented by Lyons fair.

When Rearranging Your Factory For After War Work

Plan to Keep Down Your Overhead By Labor-Saving Tools

A Drum for Hoisting Materials or Hauling Cars is a Labor-Saving Tool.

The above drum can be supplied for Belt Drive, as shown, or for Electric Drive, direct connected to a motor.

It will reduce your labor costs if used for—

- Placing cars for loading or unloading.
- Moving coal or ashes to or from the power plant.
- Running cars in or out of ovens.
- Hauling cars of materials about the factory or yard.
- Conveying articles from one machine to another in course of manufacture.
- Operating an industrial shop railway, or an overhead trolley system.

Let us help you arrange your shop lay-out so as to keep down overhead.
